The primary object of the generating station referred to above is to provide power for the operation of these pumping plants, and it is expected that several other generating stations will be constructed at various points to provide still more power. A market for surplus power can easily be found in the towns in the Salt River Valley. A temporary plant has been in operation for some years at the Roosevelt dam to supply power for the operation of the cement mill, construction machinery, lighting of the town, etc., and some of the machines in this station are to be transferred to the new power plant. The purpose of this article is to describe the controlling board which has recently been completed for installation in the new power station.

The alternating-current switchboard selected by the Government engineers for controlling the apparatus in the main station is an excellent illustration of recent "bench" control-board construction. It is of the open type, that is, there is a space left between the instrument sections and the control bench, so that the switchboard operator can have an unobstructed view of any part of the generator room without going to the end of the board, which is located at the edge of the gallery about eighteen feet above the main floor. This benchboard is equipped for the control of the following circuits, the exciter switchboard being entirely independent and of the ordinary vertical construction.

Six 2,300-volt, 1,060-kilovolt-ampere, twenty-five-cycle, three-phase, three-wire generators.

Six 2,300-volt delta, 45,000-volt Y,

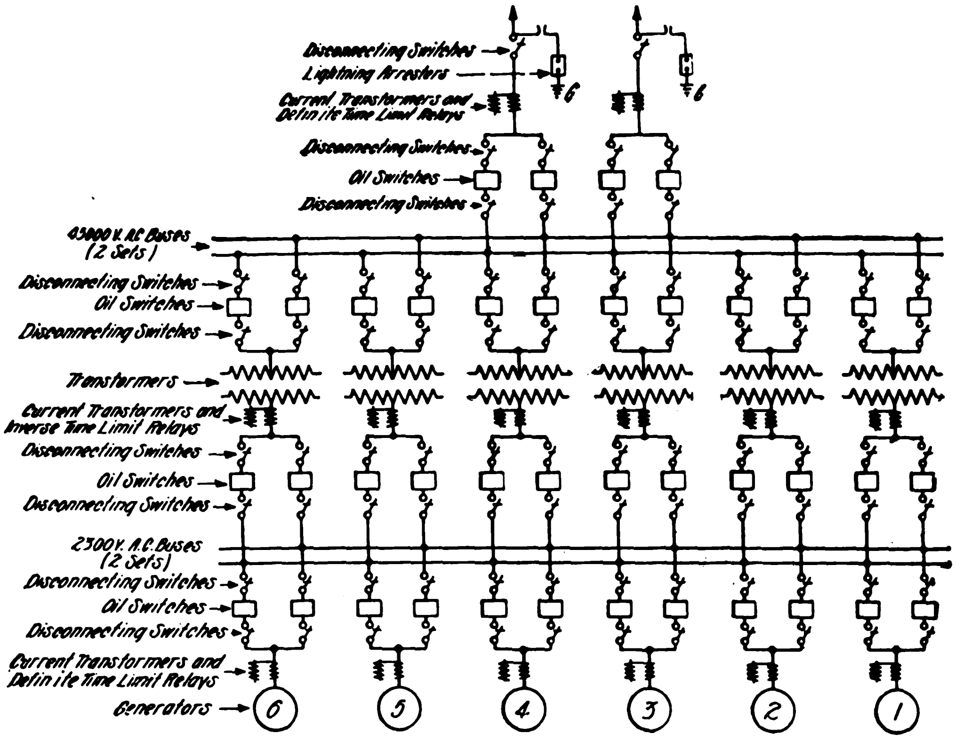

Fig. 1.—System of Connections, Switchboard for the Salt River Project of the United States Reclamation Service.

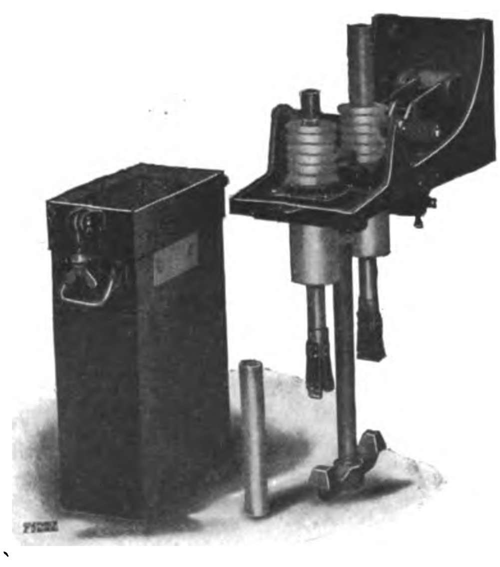

Fig. 2.—300-Ampere, 15,000-Volt Oil Switch.

Fig. 3.—100-Ampere, 45,000-Volt Oil Switch.

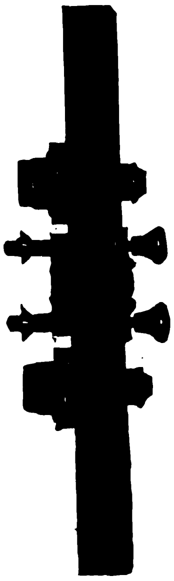

Fig. 4. — Twin Pull-Button Controlling Switch for Oil-Switch or Solenoid Control Circuit.

1,060-kilovolt-ampere, twenty-five-cycle, three-phase banks of transformers, grounded neutral.

Two 45,000-volt, 6,000-kilowatt, three-phase outgoing lines.

Fig. 1 shows the system of connections specified by the Government, one line in this diagram representing the three phases. It will be seen that both high and low-tension buses are in duplicate, allowing ample flexibility for operation, testing, inspection and repairs. Two electrically operated oil switches are used in every circuit, and complete control of the system is therefore obtained at the benchboard. This arrangement is advantageous where it is important that there be no shut-downs of an appreciable length of time. With more than two transmission lines it would probably have been advisable to modify the connections to allow of isolating any line for testing purposes after the automatic switch had been tripped by a short-circuit or other line trouble.

All protective relays used on this board are of the time-limit type in order to prevent shut-downs due to momentary overloads. The definite time-limit overload relays on the lines will, of course, be set for such a current and time that they will take care of overloads or short-circuits external to the station. Generator relays are also definite time-limit overload and will be set so that the generator switches will be tripped only on account of large exchange currents at the time of synchronizing. Inverse time-limit overload relays are used on the transformer circuits, and are so connected that trouble in any transformer will automatically disconnect all the transformers but will leave the generators operating in parallel on the low-tension bus. That the Government engineers anticipate but little trouble with the transformers is evidenced by the fact that no provision is made in the transformer-protective devices for selective operation. By using series inverse time-limit overload relays on the high-tension side of the transformers, in addition to the low-tension relays, only the defective bank of transformers would be disconnected in case of trouble.

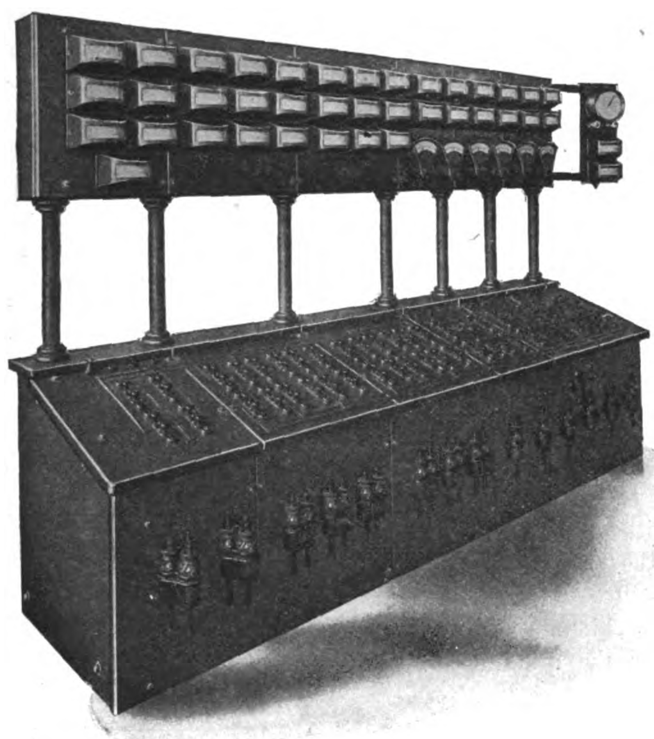

Fig. 5.—Alternating-Current and Direct-Current Switchboard, United States Reclamation Service, Salt River, Ariz.

The low-tension oil switches are the General Electric Company's standard type F form K-4, as shown in Fig. 2, each complete switch consisting of three single-pole, single-throw elements operated by a single solenoid. The switches are mounted in fireproof cells, each pole in a separate compartment, with the solenoids in small subcells. The cell doors are made of asbestos lumber with a fireproof wooden framing and are pivoted at the top, but have no fastenings at the bottom. This light, free-swinging construction of cell doors has proven preferable to heavy doors which are fastened tightly to the cells, as the effect of explosions in the cells is temporary only, so far as the door is concerned. The disconnecting switches, bus-bars and instrument transformers are mounted on pipe framework above the oil-switch cells. As will be seen from the diagram of connections, disconnecting switches are provided on both sides of every oil switch, so that any switch can be inspected, tested and repaired without shutting down any of the circuits.

The high-tension oil switches are similar in construction to the low-tension switches, and are shown in Fig. 3. These type F form K-6 switches are operated in groups of three single-pole elements by solenoids mounted on top of the switch cells. The form K-6 switch is a top-connected device, but in this case the buses and disconnecting switches are necessarily located below the oil-switch cells. The adaptability of the switch to different arrangements will be appreciated when it is stated that the only change made in the ordinary layout with the buses above the switches was an increase in the size of the cells, this being necessary in order to obtain suitable striking distance from the leads to the ground. Masonry compartments are provided for the high-tension bus-bars.

Protection against lightning is obtained by the use of a three-phase aluminum-cell lightning arrester for each transmission line, these arresters being mounted outside of the station.

The benchboard proper consists of six panels of oiled black slate, the total height, including the instrument section, being eight feet two inches, and the length, exclusive of the swinging bracket, twelve feet seven inches. Facing the switchboard, the first panel at the left controls the two outgoing lines, the next two panels each controls three banks of step-up transformers, and the three panels at the right-hand end control two generators each. The alternating-current voltmeters and the synchronism indicator are mounted on a swinging bracket at the right-hand end of the board. The back of the instrument sections and control bench is entirely enclosed by removable grille-work doors.

One alternating-current ammeter, one field ammeter and one polyphase indicating wattmeter are provided for each generator circuit. The two voltmeters on the swinging bracket are connected to the synchronizing bus in such a way that, when synchronizing, one indicates the voltage of the starting machine and the other the voltage of the bus-bars to which the incoming machine is to be connected. At other times the synchronism indicator is disconnected from the synchronizing bus by means of a small snap switch mounted on the swinging bracket, and the voltmeters can then be connected to any machine by means of the synchronizing plugs, entirely independent of the synchronism indicator.

The synchronizing and control switches and the relays are mounted on the control bench. Two synchronizing receptacles are provided for each generator, one being used when synchronizing with bus No. 1 and the other when synchronizing with bus No. 2. Two sets of contacts in these switches are used for synchronizing purposes, but the third set of contacts is connected in series with the closing side of the corresponding oil-switch control switch, so that no damage can be caused by the operator becoming excited when synchronizing and trying to close the wrong oil switch. To assist the operator in synchronizing, a governor control switch is provided for each generator circuit, this being a double-pole, double-throw reversing switch connected to the governor motor.

The controlling switches for the oil switches and field switches are the well-known twin pull-button type as shown in Fig. 4, which also shows the indicating lamps or bull's-eyes. One button actuates the closing contacts and the other the opening contacts, and they are so interlocked that it is impossible to operate both buttons together. An indicator is provided on each switch, which shows green after the control switch has been operated to open the coil switch and red after it has been operated to close it. Being a pull-button switch, it is impossible to cause trouble by accidental pressure, and, as the contacts are behind the panel, there is no danger to the operator and no chance of accidental short-circuits. Severe arcs can not occur in the control switch on account of a solenoid control relay being used to open and close the closing coil circuit of the solenoid. The use of this relay, which is mounted close to the solenoid, makes it unnecessary to run large control leads to the benchboard. The indicating lamps are connected so that they show the actual position of the main switch—red when the oil switch is closed and green when it is open. If the indicating lamps and the switch indicator do not agree the operator knows that the oil switch has tripped automatically. When this has occurred the control-switch indicator shows red and the indicating lamps green. To make the indicating lamps plainly visible from a considerable distance or at an angle, a V-shaped projection is cast on the front of the lens.

Generator field rheostats are mounted below the switchboard gallery and are controlled by combination bevel-gear and chain mechanisms, the operating hand-wheels being mounted on pedestals in front of the switchboard. The field switches are solenoid-operated and controlled from the benchboard, the same type of control switch and indicating lamps being used as for the oil switches. As stated above, the exciter and field-switch panels are of the ordinary vertical type, two sets of bus-bars being used. As the field switches are single-pole, single-throw, it is necessary to connect double-pole, double-throw lever switches in series with them so that the fields can be connected to either bus.

Mimic bus-bars are mounted on the control- switch bench, and consist of small polished copper bars which have no electrical connection with any part of the circuit. They show the system of alternating-current connections exactly as indicated in Fig. 1, the controlling switches representing the oil switches and name-plates representing the generators, transformers and lines.

The overload relays provided for the generator circuits are single-pole, the secondaries of the current transformers being cross-connected. As the generators are three-wire machines, the third line necessarily carries the resultant current of the other two current transformers. This connection can not be used on the transformer panels as three ammeters are provided for the transformer circuits, and it was, consequently, necessary to use double-pole relays. On the middle generator panel is mounted the signal relay which is used to ring an alarm bell when any of the oil switches is tripped automatically. This relay is arranged so that the bell continues ringing until the operator releases the relay, and is connected in such a way that it does not operate when the oil switches are opened or closed by the switchboard operator.

Each transformer circuit and each line is equipped with three ammeters. In addition to these instruments there is one ammeter connected in the neutral bus so as to read ground currents. Controlling circuit equipments are similar to those for the generator panels. Synchronizing receptacles are provided for the line circuits, but not for the transformer circuits, the receptacles for the line circuits being intended for use when additional generator stations are placed in operation.

In conclusion, attention is directed to the general arrangement and equipment of the board. No panel is at all crowded, the control and measuring apparatus is simple, and no superfluous or infrequently used devices are included. The equipment for each circuit is segregated so that there is no confusion in emergencies. Many recent switchboards have been unnecessarily complicated and crowded on account of including elaborate testing equipments or other devices used only at long intervals of time, the designers apparently overlooking the fact that switchboards are primarily intended for constant use in controlling the machines and circuits. Simplicity in operation involves a corresponding simplicity in design and equipment, and insures reliability, which, in the large majority of central stations, is of the greatest importance.

The switchboard described above was designed and built by the General Electric Company, of Schenectady, N. Y., to meet the requirements set forth in the Government specifications, and has just been shipped to Arizona. The photograph was taken at the factory and shows the board exactly as it will be installed.

Allis-Chalmers Business.

An officer of the Allis-Chalmers Company, of Milwaukee, Wis., is quoted as saying:

"Business booked by Allis-Chalmers in July and August showed substantial gains compared with previous months. At one time we were operating only fifty per cent of our capacity, but it has since been increased to about seventy-five per cent. All plants are now being operated.

"While all departments have recorded gains in new business, the greatest increase proportionately is shown in the demand and orders booked for mining machinery.

"We are prepared to do an electrical business on a larger scale than heretofore, and a great deal will be devoted to street-railway equipment, the bulk of which work will be performed at our West Allis plant, recently enlarged at a cost of some $5,000,000. The smaller electrical contracts will be cared for by the Bullock Electric Manufacturing Company, one of the principal subsidiary concerns.

"The foreign department is booking a good business, particularly in South Africa, Japan, China and South America."

Report of Receivers of the Metropolitan Street Railway Company.

The receivers of the Metropolitan Street Railway Company, who were, until recently, also receivers of the New York City Railway, have issued a statement showing the income account of their property from the time of their appointment on September 25, 1907, up to the end of the fiscal year on June 30, 1908.

Not taking into consideration that the company, in the nine months' period, has defaulted about $4,700,000 in rentals to lines leased or under agreements, which amount does not appear as charged against income, the deficit for the above period was $1,047,682, as follows:

Period from September 25, 1907, to June 30, 1908:

Gross earnings:		
Cash fares		$11,497,007
Ticket fares		28,438
Mail		819
Express		20,883
Total		$11,547,147
Operating expenses:		
Maintenance of way and structures	$929,012	
Maintenance of equipment	1,912,254	
Operation of power plant	899,431	
Operation of cars	3,639,086	
Injuries and damages—expended	48[illegible],813	
Injuries and damages—deferred	686,264	
General	708,076	
Total		$9,263,838
Net earnings		$2,283,308
Other income:		
Advertising	$178,108	
Rental of land and buildings	109,921	
Rental of tracks	11,109	
Rental of equipment	8,712	
Miscellaneous interest	222,016	
Other income	4,744	
Total		$533,783
Gross income		$2,817,091
Deductions from income:		
Taxes, other than special franchise	$607,424	
Taxes, special franchise, estimated on basis of assessment for year ended December 31, 1907	599,812	
Rent of leased lines on which permanent default has not been made	2,156,727	
Interest on funded debts of companies whose roads are operated under agreements on which permanent default has not been made	79,083	
Interest on real estate mortgage	36,416	
Interest on floating debt	2,112	
Claims against companies in hands of receivers	383,197	
Total		$3,864,773
Net income—deficit, not including charges defaulted		$1,047,682

In addition to the above deficit of $1,047,682, there is a further expenditure charge of $344,883, resulting from operation, about which there is a disagreement as to whether it should be charged to the Metropolitan Street Railway Company or the New York City Railway Company. Allowing for this charge and for the $4,720,114 charges on account of interest on bonds and rentals of subsidiary companies defaulted, the total deficit would approximate $6,000,000.

A statement of the default on mortgage bonds and rentals follows:

Metropolitan Street Railway Co.:			
General collateral trust mortgage	$12,500,000	@ 5%	$625,000
4% refunded mortgage	16,604,000	@ 4%	664,160
Dividend rental on capital stock	52,100,000	@ 7%	3,640,000
Third Avenue Railroad Co.:			
First mortgage	$5,000,000	@ 5%	$250,000
First consolidated mortgage	37,560,000	@ 4%	1,502,400
Dividend rental on capital stock	15,995,800	@ 6%	959,748
Central Crosstown Railroad Co.:			
Dividend rental on capital stock	$600,000	@ 15%	$90,000
Fulton Street Railroad Co.:			
First mortgage	$500,000	@ 4%	$20,000
Totals	$140,759,800		$7,751,308
Central Park, North and East Rivers Railroad Co.:			
Dividend rental on capital stock	$1,800,000	@ 9%	$162,000
Twenty-eighth and Twenty-ninth Streets Crosstown Railroad Co.:			
First mortgage	$1,500,000	@ 5%	$75,000
Totals	$3,300,000		$237,000
Grand totals	$144,059,800		$7,988,308

The statement of default covers the entire twelve months. Representatives of the company said in reference to the defaults that consideration should be taken of the fact that the company no longer received the seven per cent on $52,000,000 stock guaranteed by the Metropolitan Securities Company, which amounts annually to about $3,500,000.

Provision is made for the special franchise tax on the basis of last year's assessment, but no provision is made for depreciation.

Assuming that the Metropolitan deficit, including the charge of $344,883 in dispute, was $1,392,565 for the period from September 25, 1907, to June 30, 1908, the receivers state that if the remaining charges on account of leased lines, aggregating $2,235,810 in interest and rentals were defaulted, the road would have a surplus from operation of $800,000 after paying taxes other than special franchise of $607,424, and making provision for special franchise taxes of $599,812.

The special franchise taxes have never been paid by the surface roads, and prior to this year no provision has been made for paying them. And up to the present time no fund has been created for the purpose, but their amount has been taken into consideration in calculating the deficit on the Metropolitan system.

Receivers for Long-Distance Telephone Company of Decatur, Ala.

On petition of Frank Caughring, of Toledo, Ohio, Judge Shelby, of the United States Court of Appeals, has placed the Long-Distance Telephone Company, of Decatur, Ala., in the hands of receivers. L. G. Barker, of Louisville, Ky., and Douglass Taylor, of Huntsville, Ala., are named as receivers. The bonded debt of the company is estimated at $586,000.

New Haven's Control of the Portchester Lines.

At the hearing of the Public Service Commission for the First District, New York, in the matter of the New York & Portchester Railroad, the following statement was submitted concerning the disbursement by the New York, New Haven & Hartford Railroad Company of $11,000,000, paid for the control of the Westchester and Portchester companies:

"The New York, New Haven & Hartford Railroad Company owns 990 shares of the capital stock of the Millbrook Company out of the authorized issue of 1,000 shares, par value $100.

"The Millbrook Company owns (1) 91,581 shares of capital stock of the New York & Portchester Railroad Company, par value $100. Total issued, 91,590 (nine shares held by directors), and (2) one temporary five per cent first mortgage gold bond of New York & Portchester Railroad Company for $100,000.

"The New York & Portchester Railroad Company owns (1) 7,260 shares capital stock of the New York, Westchester & Boston Railway Company, par $100; (2) 23,614½ shares of capital stock of New York, Westchester & Boston Railway Company (voting trust certificates); (3) five shares of capital stock of the City & County Contract Company; 6,895 shares of capital stock of the City & County Contract Company (voting trust certificates); total number of shares issued City & County Contract Company capital stock is 6,890; and (4) an underwriting agreement to the amount of $13,490,000 cash to bonds and stock of New York, Westchester & Boston Railway Company. On this underwriting has been paid $4,819,120. Upon payment of balance, New York & Portchester Railway Company will be entitled to receive 13,490-13,500 of $15,000,000 par five per cent Westchester bonds and 45,000 shares of Westchester capital stock. These securities now being held under the syndicate agreement by Knickerbocker Trust Company, depositary for the syndicate managers.

"The total amount of cash advanced by the New York, New Haven & Hartford Railroad Company is $11,265,000. Of this amount $10,873,169.04 was expended in acquiring the securities of the several companies as detailed above, and the remainder, $391,830.96, is represented by demand notes or open account of the several companies. What securities will be issued against this amount can not as yet be determined."

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Kiebitz's Directive Arrangement for Electric Waves.

A brief description is given here of a directive system for electric waves which has recently been patented in Germany by Dr. F. Kiebitz. In the arrangements hitherto proposed for this purpose use has sometimes been made of some form of compound oscillator—that is, one in which an electric or open oscillator is combined with a closed oscillator. Dr. Kiebitz's device consists of a new arrangement of the compound oscillator. Although it has been tried over short distances only, sufficient data are given for an energy diagram to be plotted. In it the directed electromagnetic waves are excited by giving the radiating system such a shape that although the electric and magnetic systems generated in space have each an axis of symmetry, the two axes are in this case perpendicular or make an acute angle, while at the same time the direction of the magnetic force is inclined to that of the electric force. In this case the plane of the greatest magnetic force is inclined to the plane of the greatest electric force, the line bisecting the enclosed angle being in the direction of the greatest energy emission. The same device can be used at the receiving station, when it then absorbs chiefly those waves having the direction in which it is set. The arrangement consists of a solenoid with its ends connected to two metal surfaces. When such a system is excited inductively the electromagnetic field which it sets up consists of a magnetic doublet oscillating in the direction of the axis of the solenoid and an electric doublet oscillating in the direction connecting the two metal surfaces. The electromagnetic field thus has a minimum in the plane containing these two directions and a maximum at right angles to it. Nothing is changed when the earth is substituted for one of the metal surfaces, the direction of the maximum force then being along the earth. Experiments with this apparatus have been conducted both in the laboratory and in the open. The wavelength employed was twenty-two metres and the received energy was measured thermally. On revolving the transmitter in the laboratory a diagram of received energy was obtained having the form of a narrow lemniscate. In the open the ratio of maximum to minimum energy received was 70 to 1. A directive receiver gave the same results. With an electrolytic receiver at thirty metres, receiving distinct signals at zero degrees, rotation of the arrangement through thirty degrees caused the signals to cease. Before the practical value of the apparatus can be determined, experiments on a larger scale must be conducted.—*Abstracted from the Electrician (London), July* 31.

Weaving Concrete Poles.

A type of reinforced concrete pole, developed and used to some extent in Germany and just introduced into England, is described here. These poles are made in a machine invented by Hans Siegwart. They are hollow and tapering, in lengths up to about forty feet. The machine is capable of making columns of any size and lengths within the limits of forty feet long and two feet in diameter. Pipes can also be made in lengths three or four times as great as those customary for iron pipes. In the process of manufacture a long sheet-iron core is mounted on two trestles, running on rails, so as to be capable of rotational and longitudinal movements. Upon this core small longitudinal steel rods are fixed. The core is drawn through the machine, which is stationary. Concrete made of clean screened grit and Portland cement is mixed dry in a mechanical mixer and discharged through a chute into a hopper or drum, in which rotating paddle-wheels regularly discharge the concrete upon a bandage of coarse webbing laid on a conveyer belt, that takes one lap around the core. This continuous traveling conveyer belt is stretched so that the concrete is wrapped about the core under great pressure. As the core issues beyond the conveyer belt, wire is fed spirally around it so as to press into the concrete wrapping, and small rollers then apply great pressure by working on the webbing, the slack of which, caused by the reduction in diameter, resulting from this pressure, is taken up by another device. The core as it issues from the machine is wrapped about spirally with a bandage of cloth. The machine pulls the trestles forward with the suspended core as the concrete is wrapped on, and when the core has passed completely through the machine it is lifted by an overhead crane and laid to one side to harden. It is kept constantly damp so as to secure the maximum hardness. In about twelve hours the interior sheet metal core is reduced in diameter by means of a screw attachment inside and withdrawn. After hardening six days the bandage of webbing is removed and the pole is then complete for setting. Poles are made up to thirty-nine feet long and pipes up to twenty feet, two feet in diameter. The poles are estimated to have a life of fifty years, and during that time will cost nothing for maintenance. On this basis the total cost of an electric railway pole at the end of fifty years is estimated to be $20 for the concrete pole, $50 for an iron pole and $53 for a wooden pole, all including maintenance, repairs and renewals. This is for a twenty-nine-foot pole. For a thirty-six-foot pole for transmission service, and for the same period, the corresponding figures are: for the concrete pole, $26; for the iron pole, $68, and for the wooden pole, $68.50. Any desired amount of ornamentation may be given to the poles. Some tests on a pole of this type, thirty-two feet nine inches long, showed a deflection of two and three-quarters inches with a tensile strain of 15,000 pounds. The process is also applicable to the manufacture of concrete piles.—*Abstracted from the Electrician (London), July* 31.

The Nature of the Gamma and X-Rays.

A reply to certain criticisms of the neutral-pair theory of gamma rays, proposed by W. H. Bragg, is made here by him. Several objections have been raised by Dr. Barkla, all relating to this theory as applied to explain the behavior of secondary X-rays, as the latter thinks these rays are convincing proof of the ether-pulse theory of gamma rays. One of these refers to the equal penetrating powers of primary and secondary rays in certain cases. Mr. Bragg thinks that this is a natural consequence of any corpuscular theory. Another objection is the supposed equality in the proportion of rays of different penetrating power which are scattered. Mr. Bragg says this fact has not been conclusively proved, and if it be a fact, it is not inconsistent with the corpuscular theory. The same may be said of the proposed law of the distribution of the secondary scattered rays. The law is of limited application only, and not irreconcilable with the neutral-pair theory. Again, Dr. Barkla points out his discovery of the fact that the ratio of the quantity of secondary radiation to the quantity of primary radiation depends only on the density of the gas producing it. Others have not been able to verify this law except when used within such narrow limits that any other theory would hold equally well. Moreover, J. J. Thomson made use of this ratio in determining the number of electrons in an atom. Two other objections, related to the polarization effects, have already been answered by Mr. Bragg, and the remaining ones are based upon remarkable effects observed by Dr. Barkla and a few others, but not yet satisfactorily established. In Mr. Bragg's opinion none of the proposed theories can be considered as offering a satisfactory explanation of these phenomena, hence the neutral-pair theory is no worse off than any other. On the other hand, the ether-pulse theory will need radical alteration before it will explain satisfactorily the asymmetrical effects of the gamma rays noticed by Dr. Madsen and the author.—*Abstracted from Nature (London), July 30.*

The Teaching of Mathematics to Students of Engineering from the Standpoint of the Practising Engineer.

Mathematics is to the engineer what anatomy is to the surgeon, what chemistry is to the apothecary, what the drill is to the army officer — it is indispensable. This is the opinion of Ralph Modjeski, the well-known bridge engineer. There is much agitation at this time in France and Germany, especially in the former, favoring the limitation of the mathematical programme at present in force in the engineering schools, on the ground that it is unnecessarily extensive. From personal observation Mr. Modjeski says that the programme in the two countries mentioned covers a considerably wider range than in the average American college. In the first place, a student entering an engineering college in Europe must already know analytical geometry, the rudiments of differential and integral calculus and descriptive geometry, none of which is taught here until after the student enters college. The average length of the engineering course in Europe is four years; hence the student in the European college has more time for practical studies than the student in the American college. Mr. Modjeski believes that the time will come when only applied mathematics will be taught in the engineering college, and all necessary abstract mathematics will be required for entrance. As one result of the specialization now going on in engineering there is not the same need for advanced mathematics among all branches. The bridge engineer and the electrical engineer require more advanced mathematical training than the railroad official; while the latter needs greater knowledge in other lines, such as geology. The question then arises, Will it be desirable and possible to specialize in mathematical courses in college and adapt them to each branch of engineering? This is done at present to a limited extent only in applied mathematics. Although bridge engineers require probably as advanced training in mathematics as any other engineers, Mr. Modjeski has not found the higher mathematics which he learned at college in France of any use to him. One reason for this is that it was not taught so thoroughly as to become second nature; and unless this is the case advanced mathematical instruction is of not much value to the engineer. One can not be said to know a foreign language until he thinks in it; nor can he be said to know his mathematics until he thinks mathematically. It is not necessary for him to go to the higher mathematics, but it is necessary to be thoroughly drilled in the elementary principles of each subject. When these have become second nature, problems which arise every day in the practice of the engineer are easily solved without going into calculation. With a proper foundation the engineer's mind becomes so trained that he applies unconsciously these fundamental principles; they direct his line of thought automatically. How to secure such a foundation is the problem of the engineering college.—*Abstracted from Science (New York), August 7.*

The Petrol-Electric Drive and Other Mixed Systems.

The flexibility and serviceability of the electric transmission system for self-propelled vehicles is held by Frank Broadbent to be more than an offset to a somewhat greater fuel consumption, should this be found to result from the adoption of the system. After recalling the pioneer vehicle of this type, the Heilmann locomotive, which, he says, was not given the proper sort of trial, as it was tested in connection with steam locomotives for fairly long hauls with few stops, some of the recent systems are described. The North-Eastern Railway Company, of Great Britain, has two gasolene-electric cars in service on its Hartlepool branch. These are equipped with an eighty-five-horse-power four-cylinder engine, direct-connected to a fifty-five-kilowatt compound-wound generator which drives two fifty-horse-power motors. Several somewhat similar cars are in use in Hungary and have given good results. The fuel costs are reported to be 1.5 cents per car-kilometre. The maintenance costs are about 0.8 cent for a gasolene-electric car, which may be compared with 0.97 cent for a similar straight gasolene car; with 1.1 cents for a steam car, and 2.4 cents for a steam locomotive, all for the train-kilometre. The fuel costs for a steam car are given by the same authority as 0.9 cent, which is favorable to this system. But when all costs are considered the mixed system makes a better showing. The total costs for the steam car are given as 6.24 cents a car-kilometre, while the corresponding cost for the gasolene-electric car is only 5.73 cents. Moreover, the former figure is the average of 1,591,411 kilometres, while the latter is the average of only 135,048 kilometres, and would probably be lower for a longer use. In addition, for frequent service, where the stops are many, the better starting characteristics of the mixed system give it a decided superiority. One of the most recent systems is that proposed by Smith and Stevens. A dynamo with a falling characteristic is coupled to a gasolene engine and supplies current to two series motors. By this arrangement a constant torque is developed, irrespective of the speed. The speed is controlled by varying the speed of the engine. When the engine speed is reduced to a certain point the dynamo drops its excitation and the motors stop. Thus it is not necessary to stop the engine in order to bring the car to a standstill. For the highest speeds the resistance of the shunt field winding of the dynamo is lowered, while for the lower speeds the motors are connected in series, enabling them to develop full torque at the lowest speeds. While this system has been put forward for road vehicles, it is as suitable for local traffic on railways or any similar service. When all costs are considered it is thought that a gasolene-electric bus would show an economy of four cents a mile in running costs, and a corresponding saving should result from a proper use of this system for railway traffic.—*Abstracted from the Electrical Review (London), July 24.*

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Central Station Transformers.

The manufacture of transformers of fifty kilowatts and smaller—known among central station men as "lighting" or "central station" transformers, in contradistinction to the so-called "power" or "transmission" transformers, of sizes above fifty kilowatts—presents certain special problems which are only to be solved by manufacturers having years of experience in the design and construction of apparatus of this character. These problems are entirely apart from the question of type (whether "core type" or "shell type"), which may be a matter of individual preference or precedent on the part of the transformer builder, and which is in any event a manufacturer's question and not one in which the customer is materially interested.

The experienced builder of central station transformers must, first and foremost, understand the conditions that confront the operating companies. One of the most important of these conditions is the compulsion that the companies are under to meet their service requirements with minimum investment in transformers. This condition does not mean the selection of transformers on a criterion of low first cost; on the contrary, it means that the careful buyer, in making his yearly contracts, or in individual purchases, will give greater weight to efficiency, reliability and life than to saving in first cost of installation. The unwisdom of being blinded by the latter consideration, to the exclusion of other and more vital ones, has often been exemplified in the disappointment and loss occasioned by buying transformers of incorrect design or poor materials, or both. Such apparatus is bound to fall short in the important features of core and copper losses, insulation, cooling and general ruggedness in service—in all of which features the user is vitally interested.

Another condition is the necessity of good regulation which is recognized as essential to satisfactory lighting service, and which is essential no less to the satisfactory load performance of motors. The importance of good regulation in the latter service may be clearly shown. The prevailing types of alternating-current meters all operate on a power-factor varying from fifty to ninety per cent, depending on the percentage of load carried. On the other hand, it is well known that the load capacity of any alternating-current meter drops with the square of the fall of pressure supplied to the meter terminals. For example, a ten-horse-power motor at a pressure of 110 volts will have a capacity of only eight and one-quarter horse-power if operated on 100 volts. Since a drop of ten volts may easily occur in the transformer if the latter be of poor design with respect to regulation, the importance of the wise selection of transformers to meet such conditions is obvious.

Intimately connected with the preceding is a third condition, *viz.*, the way in which transformers of poor regulation menace the service of the central station company by shirking their load. Thus, if transformers of poor regulation are connected in parallel with transformers of good regulation, as the load increases the former will, by falling off in voltage, shift a good part of their share of the load on to the latter, which will thereby be overloaded and may even be burned out.

The Wagner Electric Manufacturing Company, of St. Louis, Mo., has specialized in the manufacture of transformers since 1891. Its experience and its recognition of the needs of the central station companies, as above outlined, have resulted in a line of central station transformers having the following operating characteristics and features of design and construction:

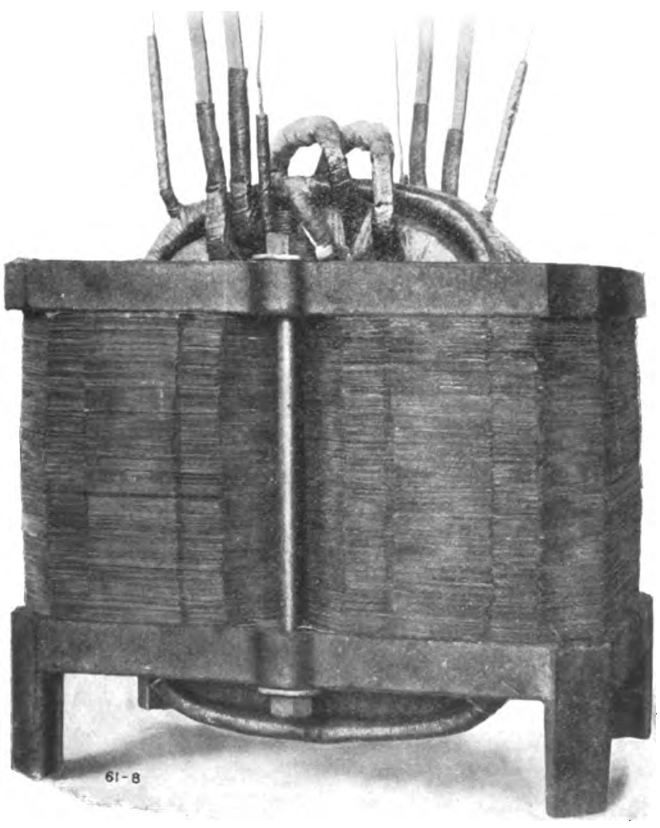

Fig. 1.—Wagner Single Central Station Transformer, with Case Removed.

In the first place the practice of this company is to employ in its central station transformers substantially the same features of electrical and mechanical design as are employed in power transformers, with the object of attaining thorough reliability in service and long life, and the maximum efficiency consistent therewith. Fig. 1 and Fig. 2 are views of the transformer element with case removed and of the complete transformer, respectively. It will be seen that the transformer is of the shell type, which is employed by all manufacturers of high-tension and large apparatus. In this form of construction the magnetic circuit of laminated sheet steel is built up around the copper coils of

Fig. 2.—Fifty-Kilowatt Wagner Central Station Transformer, Complete.

the primary and secondary windings; whereas in the core type the relative positions of magnetic circuit and copper coils are reversed—the coils enclosing the limbs of the magnetic circuit.

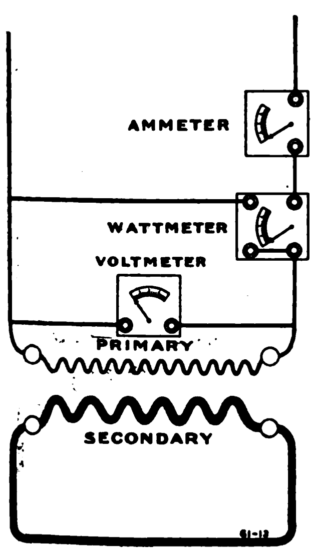

Fig. 3.—Connection for Impedance Test of Transformer.

The use of the new, so-called "alloy-steel," which the Wagner company employs, has resulted in marked advantages. Transformer cores built of this steel show not only marked reduction of initial core losses, with corresponding reduction in all-day efficiency, but also freedom from "aging" and consequent lowering of efficiency from heating of the transformer in operation.

The new steel gives a transformer having lower internal losses than has hitherto been produced, and also one in which aging is eliminated. Previous to its introduction, the operation of apparatus of this character was wisely restricted to the temperature limits prescribed by the American Institute of Electrical Engineers, for the reason that the sheet steel then employed in transformer construction aged rapidly if heated much above these limits. In the present transformers the criterion of heating is not under this restriction, but is the safe operating temperature of the insulating materials employed, although it has not been deemed wise by the company to modify the standard temperature limits that have hitherto obtained.

Unusually effective oil cooling and insulation is another salient feature of these transformers. The secret of success in properly cooling a small transformer consists in affording the oil ample opportunity to reach all the active materials. That this result is not only possible but is actually accomplished in Wagner transformers is due to the peculiarly efficient method of spacing all the parts. There are no wide individual coils in these transformers, but the coils are so subdivided as to make the interlacing layers comparatively narrow. This spacing not only permits free circulation of the oil and the maintenance of all parts at a uniform temperature, but it also reduces to the smallest working limits the pressure between layers, thereby practically eliminating the liability of puncture between them.

Wagner central station transformers do not depend upon the oil for internal insulation. All of the customary guarantee insulation tests are made upon the transformers, and sustained successfully by them, before adding the oil. The insulation of these transformers is, therefore, extraordinarily good since the effective dielectric strength of the oil is added to the already high insulation of the transformer structure due to the design. Moreover, in the construction of the transformer no insulating compounds are used that can dissolve in, or be affected by, the oil.

The attaining of excellent regulation has been made a matter of the first consideration in the design and construction of the Wagner central station transformers, which are designed with a view to their employment on either lighting or small-motor service. An approximate rule for determining whether two transformers of the same size but different makes will operate satisfactorily in parallel is to compare them on what has been termed the "impedance test" applied to each of the transformers in turn. As shown in the accompanying diagram, Fig. 3, this test consists in short-circuiting the secondary and applying an alternating current of low voltage—not exceeding two to five per cent of the normal operating voltage—to the primary, adjusting the value of the current until full-load current flows through the latter. A wattmeter inserted in the circuit will then indicate roughly the actual full-load copper loss of the transformer under service conditions. If the wattmeter and voltmeter readings are about the same for the two transformers, the latter will operate fairly well in parallel.

New Mining Property Adopting Electricity—Westinghouse Motors to Be Used.

The Virginia & Mexico Mining and Smelter Corporation, of Hostotipaquillo, Jalisco, has in transit from the Westinghouse Electric and Manufacturing Company, of Pittsburg, Pa., whose agents for the republic are Messrs. G. & O. Braniff & Company, a number of electric motors to be used in connection with its new mill. There will be some fifteen motors, totaling over 300 horse-power, the majority of which will be used for belt drive. There is to be a thirty-stamp mill, each fifteen stamps driven by a separate thirty-horse-power motor. A twenty-horse-power motor will drive ten Wilfley concentrating tables. One thirty-horse-power motor will be used to drive three crushers, and a second thirty-horse-power motor to operate air-compressor, mechanical agitator and vacuum pump. These last are for use in connection with the slime agitation and the Butters filter press which is to be installed. Another thirty-horse-power motor will be installed to drive three solution pumps and three Frenier pumps. A ten-horse-power motor will operate a Robins belt-conveyor for handling the sands, etc.

The above mill is to be one of the most modern in the republic, and the extraction obtainable will be correspondingly high, partly due to the modern machinery, and partly on account of the better efficiency obtained by the use of individual motor drives on the separate machines. Jesse Scobey is manager of the property.

Moving-Picture Machines on Alternating-Current Mains.

In the earlier days of the adaptation of the focusing arc light throwing a ray of light through a moving film, objections came from the users of alternating-current arcs, which caused the engineering department of the United Electric Light and Power Company, supplying alternating current throughout New York city, some concern. This subject is interestingly discussed by T. I. Jones in the current *Bulletin* published by the National Electric Light Association. These earlier objections included hissing at the arc, flickering and occasional black spots in the picture.

The study of this trouble showed that the black spots were most noticeable when the films had reached a given speed. This speed was found when the number of single pictures passing in front of the arc equaled the alternations per second of the current supplied. In other words, at certain times the arc was absolutely out when the picture passed in front of it; or if the arc was not actually out the difference in illumination due to the red carbon when current was absent and the incandescent carbon when current was present was sufficient to cause the black spots complained of on the screen. These black spots, therefore, had a direct bearing on the frequency of the current, as it followed that where the frequency was higher the number of spots was less and with lower frequency the spots increased.

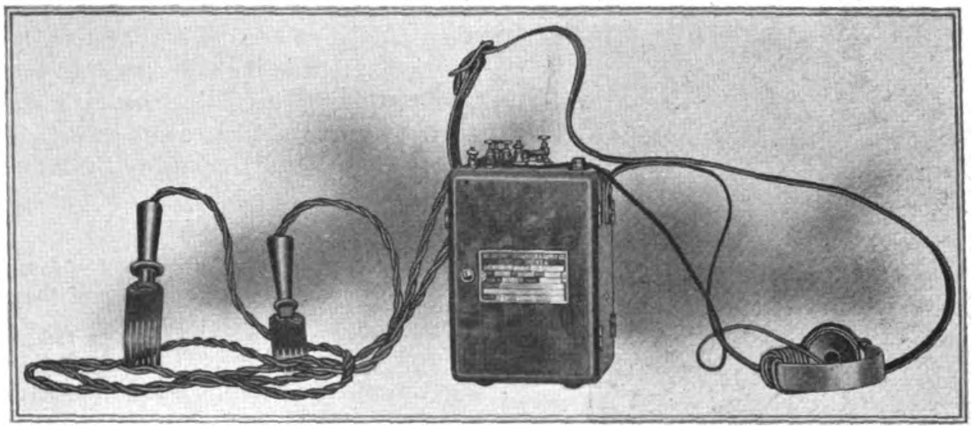
Combinations of two or more arcs were suggested, also changes of frequency of the current supplied. These suggestions, however, simply bettered without removing the condition. Accordingly, the matter of mercury rectifiers was taken up with the engineers of the United company, and in conjunction with both the Westinghouse and General Electric companies a rectifier was designed adaptable to moving-picture machines.

One of the important features in the design of the rectifier was the starting apparatus, by means of which the act of closing one switch, placed at any location, and closing the carbon switch started the entire outfit.

The direct current obtained from the rectifier removed the frequency trouble of black spots, and the use of the transformer of the rectifier outfit has a material advantage over the direct-current 110-volt street supply in that it is not necessary to use a rheostat in series with the arc to cut the voltage from 110 down to the voltage of the arc—about fifty-five. These rectifiers are now used in a number of moving-picture places in New York city.

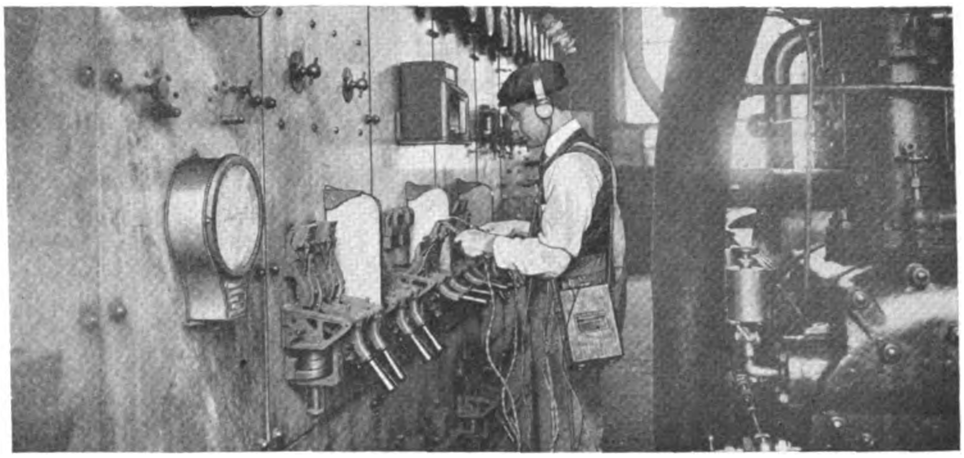
The Electric Fault Finder.

A new and useful instrument has just been brought out by the Electric Controller and Manufacturing Company, of Cleveland, Ohio, for detecting and locating grounds, short circuits, open circuits, leaks and other faults in armature coils, field coils, control circuits, switchboard wiring or any other electrical circuit. Its name, the "electric fault finder," truly describes its use since it not only indicates trouble, which is all that a magneto will do, but finds or locates the trouble. With the electric fault finder, for instance, in a motor armature a faulty coil can be absolutely located and the nature of the trouble definitely told. If a field coil is damaged the layer in which the fault lies can be absolutely determined. If there is trouble in a bunch of control wires in a multiple-unit train control, or other magnetic switch control, the faulty wire or pair of wires can be promptly located and the nature of the fault quickly found.



A New Electric Fault Finder.

As will be seen from the accompanying views, the instrument consists of a small box provided with a strap so that it can be slung over the shoulder when testing motors in place, such as under a car or on an electric overhead traveling crane. From this small box leads go to a telephone receiver fitted with a headpiece so as to leave both hands free for testing. For working in very noisy places, such as bridge and boiler shops or some parts of steel mills, the headpiece may be fitted with two receivers, one for each ear, which will shut out all sound save that received from the instrument. This arrangement not only allows perfect testing to be done in noisy places but enables partially deaf persons to use the instrument. In one case, by adjusting the rheostat to give a very loud sound (more than the normal ear could stand) and using two receivers, a very deaf man did very accurate work with this instrument. From the box leads of convenient length go also to two test terminals.

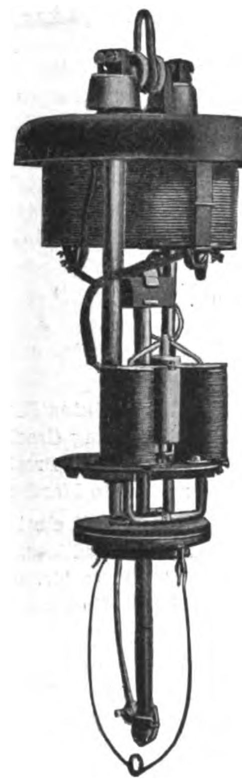


Using the Electric Fault Finder.

The electric fault finder is cheap, small, portable, and requires no outside current to operate. It requires only one man to operate under any conditions, so there is no excuse for the tester desiring a helper.

The Westinghouse 110 and 250-Volt, Multiple, Direct-Current Arc Lamps.

The Westinghouse Electric and Manufacturing Company, Pittsburg, Pa., has



INTERIOR VIEW, MILL TYPE DIRECT-CURRENT ARC LAMP.

developed a 110 and 250-volt, direct-current arc lamp for installation where the lamp may be operated under very severe conditions. The design has been adapted

EXTERIOR VIEW OF MILL TYPE DIRECT-CURRENT ARC LAMP.

especially for mills, factories and other places where a unit of delicate mechanism would not be suitable. The construction of the lamp has been simplified to the last degree, and its parts are few in number. The mechanism is of ample strength and is easy of access and thoroughly protected. The lamps are designed primarily for 110 and 250 volts, direct current, but can be adjusted to operate between the limits of 100 and 125 volts, and 200 and 260 volts, respectively. The normal current taken by these lamps when adjusted for normal voltage is four and one-half and two and three-quarters amperes, respectively. The normal life of one set of carbons is from 125 to 150 hours.

The lamp case consists of a single piece of sheet copper of cylindrical shape, finished in black japan. The mechanism of the lamp may be entirely exposed by removing the outer globe, turning the case through a small angle and lowering it. Numerous openings are made in the case through which air passes into the lamp. The air passes out through a space between the upper part of the case and the upper casting. This current of air circulates around the resistance coils in the upper part of the lamp and provides ventilation.

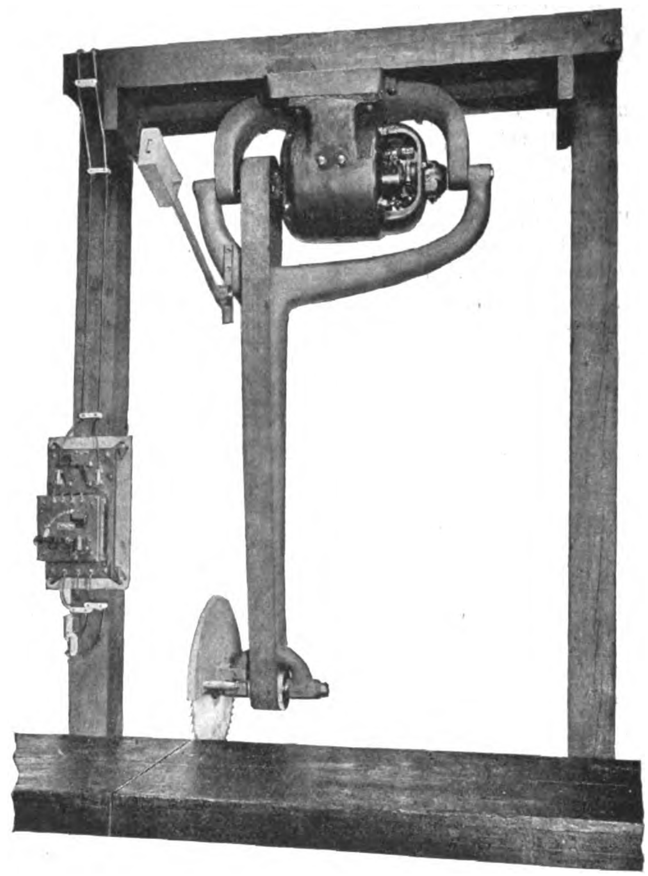
The magnet coils are wound with asbestos-covered wire and all the windings in the lamp are fireproof. The windings are so proportioned that even on a short-circuit test of several hours' duration no deterioration of the insulation nor burnouts will develop. This insures immunity from burnt-out coils whatever the exigencies of the service.

The outer globe or shade is held in place by an adjustable ring with two latches which are used for fastening the globe to the lamp housing. These latches are large and convenient to manipulate and permit the globe to be quickly released for trimming. During the operation of trimming the globe hangs suspended by a chain provided for the purpose.

Exports of copper for the first seven months of 1907 were 97,160 tons. Imports of copper for the first seven months of 1907 were 79,000 tons. Exports of copper for the first seven months of 1908 were 181,711 tons. Imports of copper for the first seven months of 1908 were 46,000 tons.—*Copper Gossip.*

The "Reliance" Electrically Driven Swing Saw.

The accompanying illustration shows the "Reliance" electrically driven swing saw placed on the market by Carse Brothers Company, 165 Broadway, New York city. In this saw compactness, simplicity and strength have been combined with great rigidity. The weight has been kept as low as is consistent with the best engineering practice. The bearings of the arbor are long, self-aligning and of the best grade of babbitt metal. The base of the saw is made in one piece, and there is no twisting, sagging or lost motion of the swinging arm. The apparatus may be mounted either on the ceiling or on a side



"RELIANCE" ELECTRICALLY DRIVEN SWING SAW.

wall. It can be supported on standards attached to a bench, and when mounted on a bench may be used as a portable tool and moved with the bench from place to place to suit the demands of the work being done.

The starting box and switch are placed in a convenient position, and the operator can start and stop the saw at will. The base supporting the motor is of cast iron, heavily ribbed, and the saw frame is a hollow cast-iron cylinder, strong and rigid. The saw is counterbalanced so that it automatically returns when the handle is released.

Current Electrical News

DOMESTIC AND EXPORT.

NORTHERN COLORADO POWER COMPANY—Harry Bronner, George C. Smith and James N. Wallace, voting trustees of the Northern Colorado Power Company announce that a meeting of the holders of voting trust certificates for preferred and common stock will be held on September 5 to vote on the authorization of a $6,000,000 issue of five per cent bonds to be secured on the property and franchises of the company.

NEW MEXICAN POWER COMPANY—The Atotonilco Light and Power Company has been organized in Guadalajara with a capital of $50,000 to install a hydroelectric plant and furnish light and power to the town of Atotonilco and to haciendas and industrial plants in the tributary territory. Atotonilco is the centre of the orange district of Jalisco. The officers of the new company are: Enrique Alvarez del Castillo, president; Francisco Muñoz, vice-president; Alfredo Gonzalez, secretary; José M. Corvera, treasurer, and Alfredo Gallardo, general manager. The other stockholders are Manuel Cuesta Gallardo, Dr. Felipe Valencia, Carlos Hering, Vicente Orendain, Frederick M. Newton, José C. Dieguez and Dr. Carlos Barriere. In the generation of electric current the new company will use the Faretan waterfall near the town of Atotonilco. The water drops a distance of seventy-five feet, and power sufficient for all needs in that section can be developed. Alfredo Gallardo, general manager of the new company, is responsible for the proposed enterprise. He planned the utilization of the waterfall and promoted the company.

NEW IOWA ELECTRIC ROAD—With a view to the construction, equipping and operating of a combination steam and electric railroad between Council Bluffs and Des Moines, Iowa, *via* Treynor, Carson, Oakland, Walnut, Elkhorn, Exira, North Branch, Guthrie Center, Panora and Dallas Center, a company with an authorized capital of $1,000,000 has been organized at Treynor, Iowa, a preliminary survey made and bonds, it is said, guaranteed. The Metropolitan Trust and Savings Bank, of Chicago, is quoted as financing the movement to a large extent, and that part of the work is practically completed. The road will be fourteen miles shorter than any now in operation. Gasolene or electricity will serve for passenger service, while steam is to be used for heavy traffic. The right of way will be secured at once and construction work begun in early spring. The officers chosen were as follows: President, G. W. Adams, Walnut; vice-president, C. L. Kirkwood, North Branch; treasurer, A. L. Ingram, Treynor; secretary, Peter Kaghmann, Treynor; general attorney, Orran Mosher, Jr., Walnut. Directors—S. B. Shultz and Arthur Saar, Treynor; V. B. Spangler, North Branch; G. L. Artist, North Branch; Charles Peterson, Walnut.

ELECTRIC RAILWAYS.

SCRANTON, PA.—Work has been begun on a new power-house for the Scranton Street Railway Company.

BROOKINGS, S. D.—The city council has granted a twenty-year franchise to the Brookings & Sioux Falls Railway Company.

APPLETON, WIS.—Plans for building an interurban line with local capital to New London by way of Hortonville are under discussion.

ALTOONA, PA.—An electric line from Altoona to Wopsononock, and over the mountain to Dougherty and Patton, is being considered by local business men.

LEWISTON, IDA.—Contracts for the grade work on the Johnson electric road between Nezperce and a connection with the Culdesac-Grangeville line have been awarded.

ARGENTA, ARK.—The town council has granted a new franchise to the Argenta Street Railway Company. The city light plant will furnish the necessary current to the railway company.

MIDDLETOWN, N. Y.—Capitalists are planning the construction within a short time of an electric railroad from Goshen to Central Valley and over the mountain to Haverstraw, to be called the Hudson River Traction Company.

KANSAS CITY, MO.—The Kansas City-Olathe Electric Railway, building south from Rosedale to Olathe, is now completed as far as Shawnee, Kan. Work is being pushed on the remaining part of the road from Shawnee to Olathe.

LOUISVILLE, KY.—The needed finances having been secured from a Boston bank, the Louisville & Eastern will complete its electric line from Louisville to Shelbyville, a distance of thirty miles. The line to Lagrange is now complete.

ELKINS, W. VA.—The power-house of the Elkins Electric Railway Company will be built by October 1 at Roaring Creek Junction, by which time it is stated cars will be running. President J. C. McSpadden states that the line will be complete to Harding this fall.

AURORA, ILL.—The Aurora, DeKalb & Rockford electric line has been sold to Edwin Bailey, of Boston, to satisfy creditors. Securities worth $835,000 par value were sold for $185,000 to Mr. Bailey, who, President Fred Dolph, of the Aurora Railway Company, says, has interests in common with him.

NEW HAVEN, CT.—The Connecticut Company, a holding corporation for the New York, New Haven & Hartford electric traction service, has awarded to C. W. Blakeslee & Sons, of this city, the contract for a trolley line from Middletown to Wethersfield, eleven miles, at an estimated cost of $400,000.

ROCK ISLAND, ILL.—At a meeting of promoters of the Rock Island Southern Interurban, from Monmouth to the tri-cities, held at Davenport, it was decided to build the connecting line in order that Aledo may be included. The line will be constructed from Preemption to Monmouth by way of Viola.

MEXICO CITY, MEXICO—The Mexico Electric Tramways Company has applied to the superior council of the federal district government for permission to build a new line to reach the new Covadonga Park of the Spanish colony in time to establish the service before the next Covadonga festivities in September.

CLARKSBURG, W. VA.—At a meeting of the Morgantown & Dunkirk Valley Traction Company, at Blacksville, it was ordered that the first section of the road, extending five miles out of Morgantown toward Wadestown, be commenced at once. Amri Martin, of Morgantown, was named as superintendent of construction.

WHITE PLAINS, N. Y.—Arrangements have been completed between the Tarrytown, White Plains & Mamaroneck Trolley Company and the Westchester Lighting Company, by which the latter is to furnish the power with which the line will be operated. Three additional lines will be strung between New Rochelle and White Plains.

PITTSBURG, PA.—A syndicate of Pittsburg and Butler men has plans for the building of an interurban traction line from Butler to Slippery Rock by way of West Sunbury. It is planned to run through cars from Pittsburg to Slippery Rock over the proposed stretch and the Pittsburg & Butler line, which would compete most of the way with the Bessemer railroad.

BILLINGS, MONT.—The sale of a franchise for an electric street railway, which was granted to Yegen Brothers by the city council some months ago, has been effected, N. S. Poole, an electrical engineer of Townsend, being the purchaser. It is stated that Yegen Brothers retain some of the stock and that a company will be organized for the purpose of constructing a line in the city and through the valley.

MASON CITY, IOWA—Charles City, Greene, Parkersburg, Allison, Grundy Center, Marshalltown and other smaller intervening points are interested in a proposed electric line from Marshalltown north to Charles City and probably beyond. Several meetings have been held and interest in the scheme has been awakened. It will take $600,000 to carry through the enterprise, and this must be raised by the cities and towns interested.

ALBANY, N. Y.—The Public Service Commission has granted permission to the Champlain & Sandford Railroad Company to construct an electric line fifty-eight miles in length in Essex County. The proposed line will tap the ore mines in the vicinity of Lake Sandford and connect with the Delaware & Hudson at Riverside. A magnetic survey shows that there are 300,000,000 tons of ore in the territory which will assay fifty per cent iron.

ALTON, ILL.—A new trolley line from Alton to Jacksonville, sixty-four miles, is in prospect through the announcement of the Alton Construction Company that work on the new Alton, Jacksonville & Peoria road will begin September 15. The line is now built from Alton to Godfrey, a little more than four miles. The money to build through to Jacksonville is said to have been pledged by a European syndicate. An extension to Peoria is planned later.

RICHMOND, VA.—Colonel C. P. E. Burgwyn and a corps of engineers have begun a survey for a railway line from West Point, on the York, to Urbanna, in Middlesex County, on the Rappahannock, a distance of about twenty-five miles. It is stated that the road is to be run with modern gasolene electric motor-cars, and will be a high-speed road traversing a section of the state now free of modern transportation facilities. Northern capitalists are said to be back of the enterprise.

OGDENSBURG, N. Y.—Representatives of New York capitalists are securing the consent of property owners to building an electric railway from this city through to Edwardsville, a distance of fourteen miles, thence across to Morristown and along the St. Lawrence River bank to Ogdensburg. The plan also contemplates a line from Edwardsville through Rossie to Gouverneur. Options will be secured later for a line from Ogdensburg to Canton, Potsdam, Massena, Louisville, Waddington and back to this city.

OKLAHOMA CITY, OKLA.—Officials of the Oklahoma City Street Railway Company are planning a number of extensions to be made within the next sixty days, to cost in the neighborhood of $50,000. John W. Shartel, vice-president and general manager of the company, has been in the East for some time looking after matters connected with improvements. It is stated that a line will be built to the state fair grounds in time for the fair in October. This line will be double track and will cost $40,000. The company is in a position to construct this line and have it in good running order by the latter part of September.

CINCINNATI, OHIO—Representative men of Erlanger, Ky., it is stated, have been at work for some time planning an extension of the Cincinnati, Newport & Covington Light and Traction Company from the St. Mary's Cemetery, on the Lexington pike, to Erlanger. Dr. James P. Riffe, who has been pushing the extension, says: "We had several interviews with Mr. Archibald White, the president of the company, and told him we would raise a subscription of $60,000 in four per cents, sufficient to pay for the extension. He assured us the extension under those conditions and it looks like a certainty now."

WELLSVILLE, OHIO—That the construction of interurban roads that will close all gaps between here and Columbus, Cleveland, Pittsburg and Cincinnati will be undertaken during the coming eight months is the belief of traction interests here. Now that a complete interurban system is open from Rochester, Pa., to Bellaire, a distance down the Ohio Valley of nearly 100 miles, attention is to be given immediately to the building of a line from Bellaire to Zanesville, on the Ohio side, and from Moundsville to Steelton, W. Va., a distance of twenty miles, and from Friendly to Williamstown, W. Va., a distance of thirty-seven miles.

GUTHRIE, OKLA.—Philadelphia capital is reported back of the proposed construction of the Oklahoma City-El Reno Electric Interurban Railway, and the work of grading is expected to commence November 15, according to statements by local promoters. The surveys have been completed between the two towns, and the work of acquiring right of way is going on gradually. A special election will be called in El Reno on the proposition for granting the street railway company a four-year extension on its franchise. The life of the franchise is twenty-one years, the company claiming that its bonds can be better disposed of if the company has a twenty-five-year franchise. The first mile of line has been completed and will be extended as soon as material arrives.

TUSCALOOSA, ALA.—The Birmingham & Gulf Construction Company has given up its contract to build the electric line from Tuscaloosa to Gadsden. By mutual agreement the contract was terminated. All of the equipment owned by the construction company has been turned over to the railroad. There have also been some changes in the officers of the Birmingham & Gulf Railway and Navigation Company. Mr. Vandergrift, who had been general manager, has been succeeded by J. T. Pultz, of New York, whose title will be general superintendent. E. F. Enslen, Jr., of Birmingham, has been appointed superintendent of the Birmingham & Gulf Railroad to succeed George H. Rois. Owing to the cancellation of the contract with the construction company the work on the line will be delayed for a short time. It is understood that a new contract will be arranged for an early conclusion.

BROOKLYN, N. Y.—The Long Island Railroad has applied to the Public Service Commission for its approval of the grant of a franchise to lay surface tracks on Atlantic avenue, Brooklyn, between Flatbush and Shepard avenues. The company claims a right of way through Atlantic avenue, but explains in the application that it is asking for a franchise for the reason that it does not wish to enter into litigation with the city. The company's claim to the right of way is based on its purchase of the rights of the old Brooklyn & Jamaica Railroad Company, which operated a surface line through Atlantic avenue. According to the application filed at this time the original grant to the Brooklyn & Jamaica Railroad Company was for a railroad from Greenpoint through Jamaica to the river's edge in Brooklyn for the term of 250 years. It is claimed that this grant gave the company "the perpetual use for railroad purposes of the thirty-foot strip in the centre of this portion of said avenue," the portion referred to being the greater length of the proposed route, and that, for the rest, a similar provision was made in the "tripartite agreement of 1855."

HOUGHTON, MICH.—At the annual meeting of the Houghton County Street Railway Company, held at the company's offices in Houghton, directors and officers for the ensuing fiscal year were elected. The election resulted as follows: President, F. J. Bawden; vice-president, F. S. Pratt; treasurer, Henry D. Sawyer; secretary, Alvah K. Todd; assistant treasurers, J. Harry Dufresne and Willard W. Dow; directors, C. A. Stone, T. E. Tripp, T. N. Perkins, Edwin S. Webster, Henry G. Bradlee, F. J. Bawden, Russell Robb, N. H. Stone and F. S. Pratt; executive committee, Henry G. Bradlee and Russell Robb. The only change made was that of F. S. Pratt in place of Henry G. Bradlee for vice-president. General Manager McGrath announced that articles of incorporation for the Houghton County Traction Company have been filed at Lansing. This company has been organized for the purpose of operating the Mohawk extension, and it is the intention of the company ultimately to take over the Houghton County Street Railway Company. The right of way for the Mohawk extension has all been secured, and nothing now stands in the way of completing the road, work on which is progressing rapidly.

BARRE, VT.—The Barre & Montpelier Power and Traction Company has closed a contract with Dornsife & Miglierini for the erection of a dam and power-house on the Winooski River, near Kinney's Mills, toward East Montpelier, that property and water rights having been purchased some time ago. When the work is completed the company will have sufficient power to run its cars between Barre and Montpelier and also for lighting purposes. It is planned to have the construction finished by November 1. The dam will be eighteen feet high and 178 feet long. Power will be transmitted from the East Montpelier side of the stream by a 600-foot penstock to the power-house, to be located near Gallup's bridge. This building will be of cement blocks and will contain two turbines, one of 350 horse-power capacity and the other of 600. There will be, in addition, an auxiliary plant, so that the company will be prepared for emergencies. At the annual meeting of the company F. M. Corry, E. H. Deavitt, I. M. Frost and T. J. Deavitt, of Montpelier, and H. K. Bush and D. M. Miles, of this city, were re-elected directors. Subsequently Frank M. Corry was re-elected president; E. H. Deavitt, clerk and treasurer; I. M. Frost, general manager, and H. K. Bush, vice-president. The reports showed that the business of the road increased during the past year. The capital stock is now $120,000.

ELECTRIC LIGHTING.

BOYERSTOWN, PA.—A site has been purchased for the proposed electric light plant, and a building forty by 100 feet will be erected.

MANCHESTER, MASS.—The proposition for the purchase of the Manchester Electric Light Company by the municipality has been defeated.

LOS ANGELES, CAL.—The directors of the Escondido Mutual Water Company have voted for the installation of an electric light and power plant to cost about $30,000.

POTTSVILLE, PA.—Contracts have been signed for the erection of a ten-mile electric transmission line in western Schuylkill. This will extend from Tower City to Lykens.

ARGENTA, ARK.—The city council has decided to expend $12,000 for additional machinery for the electric light plant to enable it to light for commercial purposes.

PASCO, WASH.—Fire destroyed the Northern Pacific Light and Power Company's plant on August 7. The plant was valued at $51,000, and was partly covered by insurance. The origin of the fire is unknown.

WASHBURN, WIS.—The city council has voted to annul the purchase of the electric lighting system from the Washburn Electric Light and Power Company. The city paid $22,580.40 for the plant but has been unable to make it pay.

ST. LOUIS, MO.—A municipal lighting plant, to supply the needs of the new city hall, municipal courts buildings and all city buildings in the downtown district, has been approved by Mayor Wells. The new plant is to cost $100,000.

SHERMAN, TEX.—At a meeting of the Sherman city council it was decided to draw up an ordinance in blank ordering an election for the issuance of bonds in the amount of $30,000, the proceeds to be used for improving the electric light and water systems.

BERLIN, MASS.—Berlin voted in special town meeting to authorize a special committee to make a contract for five years with the Marlboro Electric Light Company for electric lights in its streets. The same committee was empowered to act in regard to lighting the town hall.

PORTAGE, WIS.—Surveyors are running a line through Columbia County from Kilbourn for the Southern Wisconsin Power Company. By running through Portage, Wyocena, Rio and Columbus these towns will have the advantage of the power produced by the Kilbourn dam.

WEST CHESTER, PA.—The borough council of West Chester has made a new contract with the Edison Electric Illuminating Company to light the streets with 2,000-candle-power arc lamps at $75 each per year instead of $80 each, the price under the contract for the past five years.

CANTON, OHIO—Manager W. C. Anderson, of the Canton Electric Company, states that the contract for furnishing the city 185 arc lights or more on moonlight schedule at $41.50 per arc per year, has been returned to him from Philadelphia with the signatures of officers of the company.

MORRISTOWN, N. J.—The Morris & Somerset Electric Company has plans out for the addition to its power-house on Whippany street, made necessary for additional machinery for lighting the town, and it has taken over the Public Service Corporation's plant. Two additional 250-kilowatt generators will be put in.

MILFORD, MASS.—The Massachusetts Lighting Companies, of Boston, which operates the Milford Electric Light and Power Company, has petitioned the state gas and electric light commissioners for the right to issue $40,000 worth of first mortgage bonds to meet floating indebtedness and to further extend the local system.

MACON, GA.—By granting an amendment to the original charter, Judge Felton has allowed the Central Georgia Power Company to increase its capital stock from $100,000 to $400,000. At the same time the amendment was granted the name of the company was changed from Bibb Power Company to the Central Georgia Power Company.

ST. LOUIS, MO.—At a meeting of the United Light, Heat and Power Committee at the Planters' Hotel a subcommittee was named to make an inquiry into a proposition to build a municipal lighting plant. A resolution recommending that the city purchase the underground conduit system of the Union Electric Light and Power Company was adopted.

POTTSTOWN, PA.—Pottstown has closed a five-year contract with the Pottstown Light, Heat and Power Company for electric street lighting at the rate of $70 yearly for arc lights and $25 for incandescent, a reduction of $12.50 and $6.90, respectively, a saving to the borough of about $1,600 annually. The lighting company will make improvements costing between $15,000 and $25,000.

HOLYOKE, MASS.—The July figures for the lighting department show a gain in the output over the same month of 1,415,332 feet, or twelve and one-tenth per cent over last year. In the electric department the gain is also satisfactory, the output for last month being 360,880 kilowatts, as against 343,190 kilowatts for the same month a year ago. The greatest gain occurred in the commercial output, where a gain of twenty-four and four-tenths per cent was made.

OREGON CITY, ORE.—F. M. Swift, who is backing the project to construct an electric railway from Oregon City into the Beaver Creek, Molalla and Wilhoit Springs sections of Clackamas County, has filed notice of the appropriation of water from the main channel of the Molalla River. Swift proposes to build a canal or ditch, twenty-five feet wide at the bottom, thirty-three feet wide at the water surface, to carry an eight-foot depth of water, with a grade of two-tenths foot.

NOBLESVILLE, IND.—Ralph Wing, of Peru, and C. B. Shaber, of Arcadia, receivers for the Arcadia Electric Light Company, have reported to the court that they have sold the plant to the Noblesville Heat, Light and Power Company for $2,500, of which A. R. Holliday, of Indianapolis, is one of the largest stockholders. The court has approved the sale and discharged the receiver. The Noblesville company intends to supply Arcadia with current from Noblesville. It is already supplying Cicero and expects to extend the line to Atlanta.

WAHPETON, N. D.—Negotiations are about completed looking to the passage of a franchise which will bring water-generated electric light and power from a few miles this side of Fergus Falls, and will permit manufacturing at this railroad centre with cheap power. The total available power will be 2,000 horse. The Commercial Club has on foot a plan to connect by electric railway Sisseton with Wahpeton *via* Hankinson. The line would pass through some of the best farming land and most thickly settled country in the Dakotas, much of which is relatively far from any railroad.

ALBANY, N. Y.—The Public Service Commission has granted the application of the Williamsville Electric Light and Power Company for permission to construct and operate and exercise rights and privileges under franchises in the village of Williamsville. The order is granted upon the condition that the company will have its plant and lighting system completed and ready for supplying and distributing electricity on or before May 18, 1910. The commission has also granted the company authority to issue $25,000 of common capital stock to be used to acquire power-house and equipment. The company applied for permission to issue $35,000 stock.

CLINTON, MASS.—At a town meeting a resolution to the effect that the town acquire a plant for the manufacture and distribution of gas and electricity for municipal use and the use of its inhabitants was passed by a vote of 223 to twenty-seven. The committee that was appointed last May to investigate the subject submitted a report and was retained to make further investigation. The board of selectmen was instructed to communicate with the Clinton Gas Light Company and request them, according to law, to file with the town clerk a schedule of the property it desires to sell and the price it intends to charge. The committee's report gave some figures regarding the approximate value of the gas company's property and the result of a conference with the Metropolitan Water and Sewerage Board. From the latter the information was secured that power could be taken from the Wachusett dam at a charge of $15 per horse-power per year, and 2,500 horse-power would be available.

PERSONAL MENTION.

MR. EDWIN FERRIN has succeeded O. E. Bostick as superintendent of the Palestine Telephone Company, Palestine, Tex.

MR. CHARLES R. HUNTLEY, president of the Buffalo General Electric Company, was a visitor to New York last week in attendance at the funeral of the late Dr. William M. Habirshaw.

MR. F. H. KNOX has been made vice-president and general manager of the Electric Power and Manufacturing Company which owns and operates a street railway system, electric light and gas plants at Gaston Shoals, S. C.

DR. S. N. TAYLOR has been appointed head of the department of electrical engineering at the University of Cincinnati. Dr. Taylor has been professor of electrical engineering at the Western University of Pennsylvania for six years. Previous to that he was assistant professor of physics at Syracuse University.

MR. C. E. DUCK, formerly connected with the Waynesboro Electric Light and Power Company and Chambersburg, Greencastle & Waynesboro Street Railway Company, and who resigned from the service of the latter corporation some time ago, has accepted a position with the Carbon Transit Company, Mauch Chunk, Pa.

MR. FRANK J. QUINN, who for the past fifteen years has been associated with the Pacific Telephone and Telegraph Company as purchasing agent, and subsequently with the Western Electric Company as buyer, has become identified with the Sterling Electric Company, San Francisco, Cal., and will act as a director and treasurer of the company.

MR. ALBA H. WARREN, formerly manager of the Brockton & Plymouth Street Railway Company, of Plymouth, Mass., has assumed the management of the Pensacola (Fla.) Electric Company and the Escambia County Electric Light and Power Company, *vice* John W. Leadley, who is now on an extended vacation prior to taking up other work with the Stone & Webster interests.

MR. BEN S. REED, New Orleans manager of the Cumberland Telephone Company, has been appointed superintendent of the New Orleans district to succeed E. L. Powell, whose resignation has been announced. Mr. Reed has been in charge of the New Orleans exchanges since the beginning of this year, reorganizing the force and making many improvements. He has been manager at Owensboro, Ky.; at Chattanooga and at Louisville.

DATES AHEAD.

Colorado Electric Light, Power and Railway Association, Glenwood Springs, Col., September 16-18.

Arkansas Association of Public Utilities Operators. First annual convention, Little Rock, Ark., September 17-18.

Old Time Telegraphers' and Historical Association, and Reunion of Military Telegraphers, Niagara Falls, N. Y., September 16-18.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 5-6.

Kansas Gas, Water, Electric Light and Street Railway Association. Annual meeting, Pittsburg, Kan., October 8-10.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Railway Signal Association. Next meeting, Washington, D. C., October 13-15.

Order of the Rejuvenated Sons of Jove. Annual meeting, Buffalo, N. Y., October 15-16.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October 20-23.

ENGINEERING SOCIETY NOTE.

THE ELECTRIC CLUB OF CHICAGO—Mr. Clarence E. Freeman, of the Arnold Company, Chicago, Ill., addressed the Electric Club of Chicago on August 26 on the subject of "Irrigation and Power Development in the West."

ELECTRICAL SECURITIES.

The stock market developed considerable irregularity last week, with a distinct tendency to travel downward. Murmurings have been heard indicating that this was the result of manipulations carried on by the financial powers which have been instrumental in the upbuilding of the stock market for the past two or three months. The impression is gaining ground that a good deal of the trouble has been caused by the throwing over of investment stock which has been held for some time. The steel stocks contributed the real element of strength to the stock situation, while other metals were comparatively weak. This is essentially a period of marking time, and while the present outlook is favorable for a healthy market and increasing values, very little is being predicted one way or the other as to what turn will be made in the next two or three months.

Dividends have been declared upon the following electrical securities: Twin City Rapid Transit Company; regular quarterly dividend of 1¾ per cent on the preferred stock, payable October 1 to stock of record September 16. American Railways Company; regular dividend of 1½ per cent, payable September 15.

ELECTRICAL SECURITIES FOR THE WEEK ENDED AUGUST 22.

New York:	*Closing.*
Allis-Chalmers common	11¾
Allis-Chalmers preferred	34¼
Brooklyn Rapid Transit	51⅝

NEW PUBLICATION.

A NEW BOOK ON ELECTRICAL ENGINEERING—Robson & Adee, of Schenectady, N. Y., are preparing for publication a new book on electrical engineering by Dr. Charles P. Steinmetz. This book contains a series of lectures delivered by Professor Steinmetz under the auspices of Union University, in the winter of 1907-1908, to a class of younger engineers consisting mainly of college graduates. The lectures give a broad review of the entire field of electrical power generation, transmission, distribution, control and use, showing the close relation and dependence upon each other of all of the factors of the problem.

EDUCATIONAL NOTE.

THE ROSE POLYTECHNIC INSTITUTE—The Rose Polytechnic Institute is one of the few special technical institutes in the West. It is located at Terre Haute, Ind., and under the presidency of C. L. Mees is maintaining a high standard of excellence. The institute occupies a large and completely equipped building within the city limits, and its work is both theoretical and practical, its equipment enabling it to give its students in civil, mechanical and electrical engineering an abundance of practical work.

TELEPHONE AND TELEGRAPH.

ONEIDA N. Y.—Ground will be broken shortly for a new building for the Central New York Telephone and Telegraph Company.

NASHVILLE, TENN.—The Western Union Telegraph Company has taken over the wires on the Tennessee Central Railway between Nashville and Hopkinsville, Ky., formerly operated by the Postal Telegraph Company, and will operate them hereafter.

SPENCERPORT, N. Y.—The Ogden Telephone Company, which was organized last winter, has now practically completed the construction of its system and is furnishing service to over 300 subscribers. The Milliner Building has been leased for the Spencerport exchange and two switchboards have been placed in the building.

WICHITA, KAN.—Surveys are being made for a trunk telephone line from this city to Abilene to connect the Oklahoma service with the up-state systems. The intention is to build a later one to Omaha. One already extends from Abilene to Kansas City. The capacity of this will be doubled. The expansion of the independent service among the farming communities makes trunk lines between the cities necessary for toll service.

CENTERVILLE, N. Y.—An association, to be known as the Centerville Telephone Company, has been organized, with J. C. Vosburg, president; Victor O. Crowell, secretary, and Nelson Hauber, treasurer. Its purpose is, first, to put up a line from the post-office to the Buffalo & Susquehanna Railroad station; second, to extend a line to Fairview, four miles from here, and to create a system to cover the town of Centerville and connect with the Inter-Ocean at Rushford.

LITTLE ROCK, ARK.—The Valley Telephone Company, of Warren, contemplates an extension of its system from Warren to Dermott, *via* Monticello, a distance of forty miles. The company has 600 miles of pole line, 100 stations, thirteen exchanges and operates in seven counties. It has connection with the Cumberland at Greenville, Miss., and Lake Providence, La., and with the Southwestern Telegraph and Telephone Company at Fordyce and Pine Bluff, and has a cable across the Mississippi at Greenville. It sub-leases its instruments from the Southwestern.

REDLANDS, CAL.—A long-distance telephone line from Redlands Junction to El Paso, a distance of about 750 miles, is to be built this fall by the Consolidated Telegraph and Telephone Company, of Tucson, Ariz. The line will be the longest of the kind in the West, and a branch line which will tap the mining district of Arizona and the Imperial Valley will make the entire length 1,009 miles. The cost will be approximately $250,000. Charles A. Rolfe, of Redlands, who is identified with the Southwestern Company, of this city, has been given the contract and expects to begin work in about three months. Although the contract reads "To Redlands Junction only," the terminal point, of course, will be Los Angeles. Mr. Rolfe says it has not been decided with which company connections will be made in that city. In the construction of the line over 880,000 pounds of copper wire will be used and more than 50,000 poles.

NEW MANUFACTURING COMPANIES.

DOVER, DEL.—A charter has been filed for the Steven D. Large Company, Incorporated, Philadelphia, Pa., to engage in a general electrical engineering business. The capital is $10,000.

COLUMBUS, OHIO—The Browne-Cross Company, of Columbus, has been incorporated with a capital stock of $10,000, by Morton S. Browne, S. E. Browne, Charles W. Cross, H. H. Wilson and F. H Heywood. The company will manufacture and deal in electrical devices.

SEABRIGHT, N. J.—The Atlantic Coast Electric and Protective Company has been incorporated to manufacture burglar-alarm apparatus, with a capital of $10,000. The incorporators are: P. Hall Packer, Seabright, N. J.; Joseph Swanson, James Otterberg, New York city.

ALBANY, N. Y.—Camden & De Young, Incorporated, have filed incorporation papers with the secretary of state to carry on business as electricians, electrical engineers and general contractors. The capital is $20,000 and the directors are William Kelly, Leonard De Young and Fred Raff, of New York.

INDUSTRIAL ITEMS.

THE H. KRANTZ MANUFACTURING COMPANY, 160 Seventh street, Brooklyn, N. Y., is mailing a card calling attention to the features of the type P. C. knife switch.

THE WESTINGHOUSE TRACTION BRAKE COMPANY, Pittsburg, Pa., has ready for distribution instruction pamphlet No. T-5035, devoted to the A M S brake equipment.

THE CHICAGO PNEUMATIC TOOL COMPANY, Fisher Building, Chicago, Ill., has ready for distribution advance sheets from its catalogue No. 26, devoted to Franklin air-compressors.

THE ALLIS-CHALMERS COMPANY, Milwaukee, Wis., has issued several supplements to its instruction book 5,007. These are devoted respectively to supply parts for potential starters, type A1, type A2, type B1 and type B2.

THE PACIFIC ELECTRIC HEATING COMPANY, Ontario, Cal., has begun the publication of a little monthly entitled "Hot Points." This contains some very interesting matter concerning the electrical heating apparatus manufactured by this company.

THE NILES-BEMENT-POND COMPANY, 111 Broadway, New York city, has published a handsome catalogue devoted to Niles boring mills. Some of the illustrations show exceptional applications of electric motors to the direct driving of these important machine tools.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., has issued bulletin No. 81, devoted to central-station transformers. This takes up, in a very careful way, an analysis of the use of the new "alloy steel," with which all Wagner "Standard" and "High-Efficiency" transformers are now built. The use of this steel has resulted in marked advantages.

THE EMERSON ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., has ready for distribution bulletins No. 3,134 and No. 3,306, devoted, respectively, to single-phase induction motors, frame 24 DA, one-fortieth and one-twentieth horse-power, light-load start type, for intermittent service, and electric blowers for furnaces for alternating or direct currents.

THE ELECTRIC CONTROLLER AND MANUFACTURING COMPANY, Cleveland, Ohio, in the August issue of its attractive little bulletin, "Common Sense," devotes some descriptive matter and illustrations to the electric fault finder which the company is now calling attention to. Of course, there is the usual matter which has attracted so much attention to this excellent publication.

THE PITTSBURG TRANSFORMER COMPANY, Pittsburg, Pa., is announcing its new silico-vanadium steel transformers. The company has also completed its final designs based on the remarkable characteristics of this new alloy. The company states that core losses in Pittsburg transformers have been reduced thirty to fifty per cent, and improved copper losses and regulation have also been secured.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., has recently completed delivery on a large number of New Lexington high-tension porcelain insulators for use on the lines of the Sanitary District of Chicago. These insulators are of a new type, being fired by natural gas, and they are fully described in the insulator book which the company is now distributing. Copies of this book will be sent upon request.

THE RAILWAY SPECIALTY AND SUPPLY COMPANY, Chicago, Ill., has published bulletin T-228, describing and illustrating the Smith improved nut. This nut is made of spring steel, oil tempered. The bore of the spring end is larger than the root of the nut thread. When the nut is set tight home the spring is compressed until it rests against the main body of the nut. In this position it exerts a constant heavy pressure between the nut and the parts being held, which forces one side of the nut threads against the corresponding side of the bolt threads.

THE WYCKOFF PIPE AND CREOSOTING COMPANY, INCORPORATED, 50 Church street, New York city, states that the Degnon Contracting Company has recently removed one block of its conduit, twenty-four-duct run, the property of the Empire City Subway Company, from Sixth avenue, between Eighteenth and Nineteenth streets, New York city, owing to excavation for the Hudson River tunnels. This conduit was laid in the year 1887 and was removed in June, 1908. After twenty-one years it was sound and without the least sign of decay in any instance. The company has documentary proof of the above facts, and has samples on exhibition at its New York office which it will be pleased to show to any interested party. This conduit is being stored, as it was taken up without breakage, except a portion where it was inexpedient to pull the cables and interrupt the service.

TUNGSTEN LAMP PRICE REDUCTION—The General Electric Company announces that after September 1 there will be an extra discount of ten per cent allowed on all purchases of tungsten lamps in standard package quantities. This additional discount is made to cover all losses incident to breakage in shipment, careless handling, early burnouts, etc., and does away with the necessity of adjusting such claims with the consumer. A careful record has been kept to determine the value of the special resilient packing cases used by the General Electric Company, and the average transportation breakage in six months has been less than two per cent. Another advantage to the consumer of a different character also goes into effect the first of the month. This is a general rearrangement of the delivery schedule. Thereafter all standard package shipments to points east of the Mississippi River will be made with transportation charges allowed, and for other points, excepting a few specially designated free delivery places, a small addition to the net price will be made. The company has four factories manufacturing tungsten lamps exclusively and has a combined capacity of 35,000 lamps a day, while ample stocks are carried at eleven different district sales offices to insure prompt deliveries to any part of the country.

Record of Electrical Patents.

Week of August 18.

896,081. TELEPHONE CALL REGISTER. Byron B. Brockway, Cleveland, Ohio, assignor to the Dean Electric Company, Elyria, Ohio. The register is made a part of, and attached to, the diaphragm containing receptacle.

896,092. ELASTIC SUSPENSION FOR THE FILAMENTS OF ELECTRIC INCANDESCENT LAMPS. Paul Druseidt, Remscheid, Germany. The stem is spring-supported in three different places.

896,103. TELEPHONE SYSTEM. Charles L. Goodrum, Philadelphia, Pa., assignor, by mesne assignments, to the Dean Electric Company, Elyria, Ohio. A metallic-circuit central exchange and substations.

896,120. ELECTRICALLY OPERATED VALVE. Christian Krämer, Frankfort-on-the-Main, Germany, assignor to Felten & Guilleaume-Lahmeyerwerke Actien-Gesellschaft, Frankfort-on-the-Main, Germany. The closure is effected by means of a stem working in an electromagnet.

896,122. PLURAL LAMP SOCKET. Edward A. Lefèbre, Jr., Brooklyn, N. Y. The threaded base is equipped with a plurality of contact shells and socket-held plates.

896,130. RECEIVER FOR WIRELESS TELEGRAPHY. Guglielmo Marconi, London, England, assignor to Marconi Wireless Telegraph Company of America, New York, N. Y. The oscillation valve and primary winding of the induction coil are connected in series with each other, but in shunt with the condenser.

896,144. ELECTRODE. Harry Pauling, Gelsenkirchen, Germany, assignor to the firm of Salpetersäure-Industrie-Gesellschaft, G. M. B. H., Gelsenkirchen, Germany. Melted oxides are formed and maintained in their liquid state by the treatment of gases by arc discharges.

896,165. FAN. Otto Selg, New York, N. Y. The fan is fitted with an annular slitted deflector having a series of V-shaped blades.

896 173. TELEPHONE APPARATUS. James H. Thompson, Trenton, N. J. The bell box is provided with a drum for winding up the slack telephone cord.

896,184. APPARATUS FOR THE ELECTROLYSIS OF FLUIDS. Emil Weichert, Augsburg, Germany. The electrodes are fitted in conjunction with the convolution of each coil.

896,188. SYSTEM OF STORAGE-BATTERY CONTROL. Edward Wray, Janesville, Wis. An electromagnetic latch holds the switch arm locked when a battery is being charged.

896,189. ELECTRIC TROLLEY. John Young, Toledo, Ohio. The trolley wheel is carried in an eccentrically mounted case suspended from the trolley harp.

896,192. TERMINAL PIECE FOR ELECTRIC CIRCUIT-BREAKERS. Christian Aalborg, Wilkinsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. The terminal piece is composed of a plurality of cylindrical radially slotted lamina having an inwardly tapered open end.

896,198. TROLLEY POLE. Lawrence C. Collins and Arthur R. Eltom, Cranford, N. J. The self-seating trolley pole is provided with inner and outer telescoping members.

896,200. BRANCH CONNECTION FOR ELECTRIC CABLES. John J. Dossert, New York, N. Y., assignor, by direct and mesne assignments, to Dossert & Company. The conducting yokes are adapted to be brought into contact with the cable on diametrically opposite sides.

896,210. CONTACT MEMBER. Henry D. James, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. An end recess engages with a projecting plug of materially smaller section, located in the recess of a co-operating contact member.

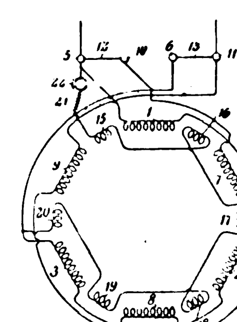
896,216. ELECTRICALLY PROPELLED VEHICLE. Louis Krieger, Paris, France. The battery, through a resistance, floats in the generator circuit.

896,217. WINDING FOR SINGLE-PHASE INDUCTION MOTORS. Fred R. Kunkel, Edgewood Park, Pa., assignor to Westinghouse Electric and Manufacturing Company. The main winding of the motor is adapted to be connected in either series or parallel relation with an auxiliary winding.

896,218. ELECTRIC WELDING MACHINE. Laurence S. Lachman, New York, N. Y. A spot-welding pole connected to a source of current, and a cross-sectional area large enough to give it rigidity.

896,220. ELECTRIC LOCOMOTIVE. Benjamin G. Lamme and Norman W. Storer, Pittsburg, Pa., assignors to Westinghouse Electric and Manufacturing Company. The axle is mounted upon quills, and the motor is resiliently connected to the axle.

896,222. ELECTRICAL MEASURING INSTRUMENT. Paul MacGahan, Wilkinsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. A graphic recording meter.



896,217.—WINDING FOR SINGLE-PHASE INDUCTION MOTORS.

896,225. MEANS FOR AUTOMATICALLY RESTORING A TROLLEY WHEEL TO THE WIRE. Charles F. Mehl, Cleveland, Ohio. An auxiliary wheel carried upon a solenoid-operated plunger finds the position on the wire for the main trolley wheel.

896,227. MEANS FOR REGULATING THE SUPPLY OF ELECTRIC CURRENTS. Charles M. P. Montbarbon, Paris, France. One terminal of the generator armature is grounded and electrically connected through contact plates connected to the other terminal of the armature.

896,243. GAS OR VAPOR ELECTRIC APPARATUS. Max von Recklinghausen, New York, N. Y., assignor to Cooper Hewitt Electric Company. A continuous conductor is hermetically sealed in a container in an intervening gas or vapor.

896,249. ELECTRIC MOTOR CONTROL. Girard B. Rosenblatt, Butte, Mont., assignor to Westinghouse Electric and Manufacturing Company. Means for coupling together two asynchronous motors.

896,252. MEANS FOR ATTACHING METALLIC FILAMENTS TO THEIR CARRIER ARMS. Johannes Schilling, Halensee, near Berlin, Germany. The stem is provided with carrier arms.

896,274. ARC LAMP. Guy N. Chamberlin, Lynn, Mass., assignor to General Electric Company. The movement of the electrode automatically varies the rate at which air is supplied to the inner globe.

896,297. ELECTRIC HEATER. Edward M. Hewlett, Schenectady, N. Y., assignor to General Electric Company. The grid-shaped resistance strip is folded back and forth upon itself in parallel sections.

896,300. ELECTRICAL TESTING INSTRUMENT. Cameron De Witt Jarvis, Winthrop, Mass., assignor to American Telephone and Telegraph Company. The contact clips terminate in a cartridge containing a resistance coil and an indicating member.

896,319. CURRENT COLLECTOR FOR ELECTRIC RAILWAYS. Philipp Pforr, Lankwitz, near Berlin, and Paul E. Herkner, Berlin, Germany. The current collectors are operated by fluid pressure mechanisms.

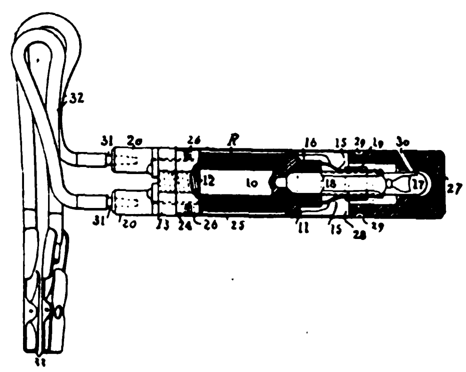
896,321. FIELD-MAGNET STRUCTURE. Henry G. Reist, Schenectady, N. Y., assignor to General Electric Company. The structure is composed of alternate large and small polygonal units each comprising a plurality of lamina riveted together.

896,322. DYNAMOELECTRIC MACHINE. Henry G. Reist, Schenectady, N. Y., assignor to General Electric Company. The laminated pole piece is equipped with removable tips.

896,323. DYNAMOELECTRIC MACHINE. Henry G. Reist, Schenectady, N. Y., assignor to General Electric Company. The field magnet is made up of staggered long and short polar portions.

896,332. AUTOMATIC TRAIN STOP. Hiram G. Sedgwick, Mill Valley, Cal. The stop mechanism on the train is actuated by an electromagnet placed in the roadbed.

896,341. FILAMENT FOR INCANDESCENT LAMPS. Willis R. Whitney, Schenectady, N. Y., assignor to General Electric Company. The filament is formed substantially of a nitride of a rare earth metal.



896,300.—ELECTRICAL TESTING INSTRUMENT.

896,348. CIGAR LIGHTER. Eskil Berg, Schenectady, N. Y., assignor to General Electric Company. The heating unit is contained in a capsule covered by a perforated shield.

896,350. STORAGE-BATTERY ELEMENT. John Bimeler, Zoar, Ohio, assignor of one-tenth to the Zoar Battery Company, Zoar, Ohio. The element is built up of a leaf structure, forming an open-work frame of large active area.

896,397. PENCIL AND APPARATUS FOR PRODUCING THE ARC LIGHT. Isador Ladoff, Cleveland, Ohio, assignor of thirty one-hundredths to Philip C. Peck, New York, N. Y. The electrode is composed of copper and titanium, and an alloy of copper and titanium.

896,416. TELEGRAPHONE. Hermann Schütte, Wheeling, W. Va. The speed of the telegraphone disc is adjusted by a clockwork and spring mechanism.

896,417. ARC LAMP. Ralph Scott, Wilkes-Barre, Pa., assignor to Scott Electrical Company. The feeding mechanism is actuated by a magnet.

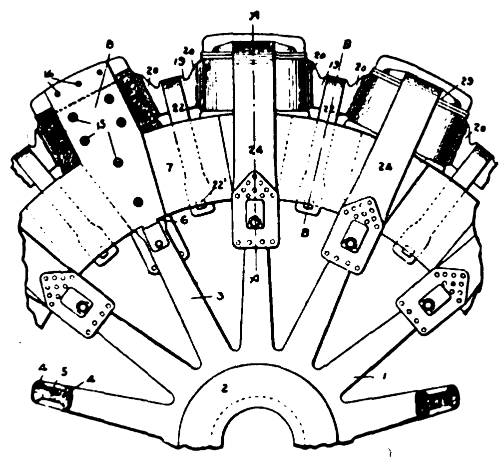
896,429. ELECTRODE FOR ELECTRIC FURNACES. Frederick M. Becket, Niagara Falls, N. Y., assignor by mesne assignments to Winthrop Chanler. The electrode has a metallic body portion, the interior of which is hollow or chambered, and an exterior coat or shell of carbon.

896,463. FIREPROOF SUPPORT FOR ELECTRICAL WIRES IN RAILWAY CARS. Edward T. Robinson, St. Louis, Mo., assignor to St. Louis Car Company, St. Louis, Mo. An insulating molding strip with a conduit for angle and corner work.

896,469. MAGNETIC CIRCUIT-BREAKER. Ralph Scott, New Brunswick, N. J., assignor to Scott Electrical Company. The contact members have recesses and prominences in their opposing faces.

896,476. CRIMPING APPARATUS FOR ELECTRIC WELDING MACHINES. Herbert L. Smith, Clinton, Mass., assignor to Clinton Wire Cloth Company, Boston, Mass. The apparatus is adjustable for making a crimp of any desired proportions.

896,516. MOTOR-CONTROL SYSTEM. Herbert W. Cheney, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. The single controller is arranged so that it can control either of the two motors separately, but is prevented from controlling them both together, and can leave one motor running while it controls the other.



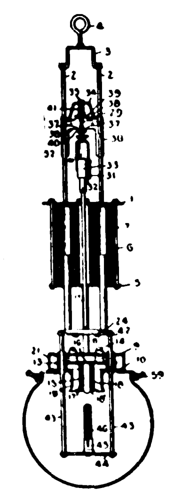
896,323.—DYNAMOELECTRIC MACHINE.

896,555. ELECTROLYTIC CELL. Gilbert C. Landis, York, Pa. A container having a number of removable frames, each frame being provided with a plurality of plates parallel to each other.

896,584. ELECTRICAL APPARATUS FOR TRANSMITTING SIGNALS. Charles Salmon and Henry J. Creffield, Erith, England, assignors to Vickers Sons & Maxim, Limited, Westminster, England. The several indicating stations are in series with the central signaling system.

896,586. MAKE-AND-BREAK DEVICE. Dominic Sandretto, Ladd, Ill. A bar pivotally mounted operates a step-by-step mechanism upon the energizing of an electromagnet.

896,608. ARRANGEMENT OF THE WINDING OF ELECTROMAGNETIC CLUTCHES. Heinrich Ast, Vienna, Austria-Hungary, assignor to the firm of Vulkan Maschinenfabriks-Actien-Gesellschaft, Vienna, Austria-Hungary. The magnet body contains an annular channel-shaped casing adapted to retain the winding.



896,698.—ARC LAMP.

896,617. TELEPHONE SWITCHBOARD APPARATUS. Lewis A. Brinkman, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. An operator's key shelf equipped with listening and ringing key, visual signal, and plugs.

896,630. ELECTRICAL HEATING MEANS FOR MOLDS. Harry E. Diller, Oak Park, Ill. The metal forms a part of the electrical conducting circuit.

896,698. ARC LAMP. Charles P. Steinmetz and John T. H. Dempster, Schenectady, N. Y., assignors to General Electric Company. One electrode is moved by gravity and the other by an electromagnet.

TANTALUM DETECTOR FOR WIRELESS SIGNALING.

During the past year or two innumerable detectors for electric waves, acting on the imperfect-contact principle, have been devised. Many of these have not been self-decohering, but occasionally a combination of metals or of a metal and some other conducting body is found which is self-restoring. Usually detectors of the latter type employ a compound of a metal, such as a carbide. The arrangements using metal on metal generally call for a mechanical arrangement for restoring the high resistance of the receptive condition. An interesting detector of this type was invented a year or so ago, and used in the Lodge-Muirhead system. This device was formed by rotating a small metallic wheel, the lower surface of which just grazed a surface of mercury covered with a thin film of oil. The rotation of the wheel served to restore the high resistance of the device, which apparently was due to a very thin film of oil adhering to the surface of the disc. This film appears to be so thin that it is punctured by the potentials produced when an electric wave is received by the antenna.

On another page of this issue a wave detector is described which employs mercury as one of the contacts and a tantalum wire as the other. The wire is exceedingly fine, being only about five-hundredths millimetre in diameter; in fact, it is nothing more than a short piece of filament taken from one of the ordinary tantalum lamps. Tantalum is not wetted by mercury, and when this fine wire is just in contact with a mercury surface the contact resistance is from 1,000 to 2,000 ohms. This resistance is not high compared with the receptive resistance of certain other receivers, but when an oscillation is received the resistance drops to about one-eighth of its original value. This ratio can even be increased if desired and the great change gives rise to very loud signals. The inventor of the detector, Mr. L. H. Walter, says that in this respect his detector is superior to most others, although it is not so sensitive as some other types for very weak oscillations. This characteristic he thinks makes the detector particularly suitable for wireless telegraphy, since the oscillation currents used in that system of communication must necessarily be relatively powerful.

Finding the combination of tantalum and mercury so excellent, Mr. Walter tried various other combinations of metals, both with mercury and with other metals; none of them, however, compared with the tantalum-mercury couple. He did find one combination of solid metals, namely, tantalum and oxidized iron, which gave fairly satisfactory results. Such an arrangement would be well adapted for use on shipboard, where the vibration of the mercury surface of the other detectors would render them useless. However, the inventor has devised an arrangement of his mercury-tantalum detector in which the tantalum wire is in contact with a small globule of mercury entirely enclosed, and which therefore does not vibrate.

It is an interesting question as to what gives rise to this high resistance of contact. One would at first attribute it to a thin film of oxide, similar though not so strong dielectrically as the coating of oxide which forms on the aluminum plates used in electrolytic rectifiers or condensers. Such a film might be easily formed if the tantalum and mercury were momentarily separated, but when the surface of contact is entirely below the upper surface of mercury, one would hardly expect such a coating of oxide to repair itself after puncture. Another explanation might be that a thin film of air adhered to the mercury. This would prevent the latter from wetting the tantalum, but the same difficulty of explaining the self-restoring effect is met. If this thin film of air behaved as a liquid, it might be said that its surface tension repaired the break; possibly there is some such effect.

THE BOSTON EDISON RATE DECISION.

After a long investigation of the methods of charging and the rates of the Edison Electric Illuminating Company of Boston, the Massachusetts Gas and Electric Light Commission has gone squarely on record against the modified Wright-demand system used by the company, taking the ground that it is practically impossible to determine accurately the cost of supplying an individual customer, and so to proportion the charges that each customer will bear his proper share of the burden of furnishing him with service. Incidentally, a reduction in rates is recommended, but the broad general interest in the decision of the board lies in the fundamental discussion it presents of the intricate problem of central station rate making.

In summarizing its explanation of electric lighting costs the company has stated that the costs of an electric lighting company are actually the sum of what its customers' costs would be if they supplied themselves under the different conditions under which they consume current, less such deduction as is justified by the use of the plant by different customers, and such deduction as is justified by the greater economy of the company's larger plant. To make costs the basis the company divides its annual expenses into "fixed" and "running" costs. In the latter it includes only those costs which are reasonably certain to vary with the amount of current made and sold, including coal, oil and waste, water, station wages, carbons and incandescent lamps. All other expenses, including dividends, are included in "fixed" costs. The "running" costs are obtained readily by meter and operating expense records. The "fixed" costs for each kilowatt of station demand are obtained by dividing the fixed costs for the year by the number of kilowatts representing the maximum station demand. The customer's maximum demand is determined by the Wright indicator, but to allow for the fact that all the maximum demands do not come at the same time, the company modifies its rates by a so-called "diversity factor," which it defines as the ratio of the sum of its customer's demands to the actual station demand. Feeling that the cost of distributing current to small consumers is proportionally much larger than to heavy consumers, the company has introduced wholesale discounts to relieve the large customers of the excess costs occasioned by the smaller customers. A year's experience with the yearly contract lighting rate shows an average rate of 7.2 cents per kilowatt-hour; with the non-contract lighting rate, 14.2 cents; with the power rate, 5.6 cents, and with the elevator rate, where the demand system is not used, 8.5 cents.

The board points out that the justification of a system of individual rates must rest upon the practicability of ascertaining with reasonable accuracy the cost of supplying each individual customer, and of automatically apportioning this cost to him by the schedule of prices adopted. The board states that the ratio of a customer's maximum demand to the aggregate maximum demands of all customers does not, aside from the practical difficulty of ascertaining the ratio, determine the customer's proportion of the fixed costs, because actual conditions require the recognition of the so-called "diversity factors." In the year ended June 30, 1907, the maximum station load was 35,310 kilowatts as against over 48,000 kilowatts, the aggregate of the customer's demands as nearly as they could be ascertained or estimated. The diversity factors were not based upon the company's experience nor that of others supplying electricity under similar conditions. They are of the greatest importance, introduced to so correct the relation of an individual customer's maximum demand to the maximum demands of all customers that his responsibility for the station peak, and therefore of the company's investment because of it, shall be correctly proportioned. Accuracy in this process, according to the board, requires that before the "diversity factors" are used the "fixed costs" shall be divided as between lighting and power or any portion of the company's business to which they are applicable. "Such a division," says the board, "is obviously impracticable, and without it there is no demonstration that the resulting charge to the individual is proportional to his cost."

In its decision the commission states that even the "diversity factor" assumes that the cost of supplying the individual customer is based on certain average conditions, since the maximum demand may vary widely from time to time. It also criticizes the inclusion of dividends and general expenses of management in the fixed costs, and urges that it is doubtful if it is practicable, even though desirable, to ascertain the costs to the company of its individual customers and to apportion such costs in the prices charged. Finally, emphasis is laid upon the desirability of every public service charge being simple, definite and readily understood and applied.

In accepting the board's recommendation as to rate reduction, President Edgar states that the company does not wish to be understood as admitting the incorrectness of its theory of differential prices or the incompleteness of its proof that its prices are based upon cost. In view of the thorough study of the rate problem which all the parties in interest have given it in Massachusetts during the past year, and in the light of the board's decision, the continued ability of the demand system to stand the test of time will be an interesting matter to observe.

THE TRACKLESS TROLLEY FOR DUNDEE.

A number of interesting traffic problems have arisen lately in Great Britain, one or two of which we have commented upon. One of the newest, worthy of note not because of its importance so much as on account of the proposed solution, is that described in our contemporary, *Electrical Engineering,* of London. It seems that the city of Dundee feels a strong need for some traffic accommodation on the Clepington road. The traffic there is not sufficient to warrant the expense of a street railway, so that various form of motor buses have been under consideration. After a careful investigation made by a subcommittee of the tramway committee of the Dundee Town Council, during which the subcommittee inspected a number of so-called trackless trolley systems in service on the Continent of Europe, it has submitted a report recommending the installation of such a system on the route mentioned.

It will be very interesting, should the recommendations of the committee be followed, to watch the success of this system. Several years ago there was a good deal of talk about the advantages of the trackless trolley for routes where the traffic is light. But, with the exception of three or four installations in Europe, the decision seems always to have been in favor of a railway.

Among the systems inspected by the subcommittee was that at Monnheim, Germany. This connects Monnheim with the railway station of Langenfeld, the distance being about two and one-half miles. It has been in service for a number of years; when first started the traffic was light, but it has since built up a traffic sufficient to warrant the laying down of rails, which is soon to be done. The result here is precisely what was predicted would happen. The inexpensive trackless system saves the greater part of the expense of the street railway; it thus greatly reduces the risk and determines whether there is sufficient need for a railway. An incidental advantage of the system is that it can be so constructed as to make but slight change necessary in the overhead structure when the tracks are laid.

Another system inspected by the committee was that connecting the towns of Ahrweiler, Neuenahr and Walporzheim. This system was put in service a little over two years ago. In many places the streets are very narrow, the paving is rough, though between the towns the roads are fairly good. The motor-car carries baggage and draws a trailer seating twenty passengers. A speed of fourteen miles an hour is made, and it is said that the actual results show a consumption of energy of only 0.67 kilowatt-hour per mile run. This figure seems very low considering the unfavorable road conditions existing in places and the fact that the motor-car draws a trailer.

Still a third system investigated was that at Mulhausen, where it is said the most recent installation exists. This system was installed to connect the zoological gardens of the town with the electrical line. The company operating the latter said that the traffic was too intermittent to make an extension of its system profitable, and at the same time the grades were too steep for a railway to operate successfully, therefore a trackless trolley system was constructed and put in service during last May. The cars are light and well equipped and have been provided with emergency brakes. The subcommittee was so well pleased with the operation of this line that it recommends that a similar system, somewhat modified, be used for Dundee.

The advantages of the trackless trolley system are its suitability for just such conditions as have been described above. The greatest drawback of the system would be assumed to be the large energy consumption due to the fact that the cars do not run on rails, but if the figure given above is reliable, it is evident that a properly constructed car can be operated over moderately good roads without requiring an excessive supply of energy. The system, of course, avoids the expense of laying a track, and does not add this impediment to other traffic. It does, however, require two overhead wires, since a ground return is impracticable, but the overhead structure could generally be light and placed where it is least objectionable. It is evident, from the report to which we have referred, that very good speeds can be obtained. Fourteen miles an hour is fast enough for such light traffic as could be handled by a system of this kind. Possibly, when the success of these foreign installations is better realized, the system itself will receive more attention elsewhere.

A HIGH-TENSION TRANSMISSION DECISION.

Last March proceedings were begun by the Commissioner of Water Supply, Gas and Electricity of New York city against the New York Central & Hudson River Railroad Company looking to the compelling of the railroad company to place under ground its high-tension feeders supplying current to its electrical zone for the operation of its third-rail system. Hearings have been conducted before the Public Service Commission of the First District. While the commission does not approve of aerial transmission lines, it holds that as long as this line is safe, and the testimony and evidence presented, it avers, did not prove it unsafe, it would seem to be a great injustice to the company to compel it to destroy its present lines, and to place its high-tension transmission system under ground. Other suggestions made by the commissioner are either overruled or modified. The decision, on the whole, is favorable to the company and is an indication that this commission is not prepared to indulge in high-handed or arbitrary procedure.

During the hearings it was shown by testimony that in addition to the high-tension system of the New York Central and the Long Island Railroad system there are at present maintained in the city of New York, presumably under permits from the city, five hundred and thirteen miles of overhead line operating at from one thousand to three thousand volts, and forty-seven miles operating at from three thousand to eleven thousand volts, for electric light and railway service and strung along the public streets.

Ohio Electric Light Association.

Fourteenth Annual Convention, Held at Hotel Victory, Put-in-Bay, Lake Erie, August 25, 26 and 27.

THE fourteenth annual convention of the Ohio Electric Light Association, held at Put-in-Bay, Lake Erie, on August 25, 26 and 27, 1908, combined to a larger degree than ever before in the history of this association the social and the business elements. While the committees in charge of the entertainment features, which were many and varied, performed their duties with good taste, energy and judgment, the business features received equally adequate treatment and full preparation, so that the papers read were pithy and suggestive, and above all brief and to the point, and were business-getters. They brought out in nearly all cases full and free discussion. If the work of an association is to be judged by results in increased membership and better turnout of the membership to the conventions every year, the Ohio Electric Light Association is certainly maintaining its position as one of the best of the state associations in the country.

TUESDAY AFTERNOON SESSION.

Secretary Gaskill called the convention to order at two o'clock on Tuesday afternoon, and announced that in the absence of President F. M. Tait, of the Dayton Lighting Company, ex-President W. P. Engel, of Defiance, would preside during the opening session.

The first order of business was a paper by William M. Adams, of Elyria, Ohio, on "Gas Engines in Central Station Work." Mr. Adams advocated very strongly the employment of gas engines in place of steam where gas is available, on account of the decreased cost of operation, and he gave figures covering four years' experience with these engines.

Mr. Adams stated that his company had run two engines since a year ago last April and had never lost any time during that period. Last spring they remodeled the plant entirely and did not shut down one minute. These were two Westinghouse 280-horse-power, three-cylinder, and one Struthers-Wells of 258 horse-power. They use a single system of ignition, with a duplicate set of batteries so as to provide for a battery giving out.

He said that it takes a good man to run a gas engine. They pay more for gas engineers than for steam engineers when they find the right man. Where they could get a steam engineer for $65 they pay $70 or $75 for a gas engineer. The engine was guaranteed for 250 horse-power, twenty-five per cent overload. It ran twenty-five per cent over the guarantee. During one period of twenty-four hours it ran all the way from 250 to 330 horse-power under water rheostat test.

The next paper was entitled "A Report on Gas Producer and Oil Engine Plants," contributed by B. H. Smith, of the Lexington electric plant.

This paper describes a suction gas-producer plant operated by the Lexington Electric Light Company, Lexington, Ohio. This consists of a twenty-five-horse-power suction gas producer and a 100-horse-power producer gas engine. The dynamo is a seventeen-kilowatt, 125-volt, direct-current machine. The producer is an antiquated type built in 1902, using anthracite coal. With an average load of 10.2 kilowatts, and a run of five and one-quarter hours, 271 pounds of coal are consumed, including a stand-over loss of three pounds per hour. Deducting fifty-six pounds for stand-over, the fuel consumption during the run is 215 pounds, or 2.2 pounds per horse-power-hour or four pounds per kilowatt-hour. With coal at $4.90 a ton, the cost for fuel is one cent per kilowatt-hour. The entire cost, including oil, attendance, etc., is four cents per kilowatt-hour. The preparation of the plant for the run takes about an hour. Oiling the engine, cleaning and timing the igniters, cleaning, barring and blowing the fire in the producer, sum up the usual preparatory service. The engine receives the greater part of the attention necessary during the run. The igniters have given but little trouble. The repairs on the producer have not exceeded $5 per year. The upkeep of the engine will probably amount to $30 per year.

S. E. Folk, of Bryan, said he had been operating a Diesel engine for about a year with entire satisfaction. The economy of the engine has been remarkable, current at the switchboard costing three and one-half to four cents per kilowatt-hour, including interest, sinking fund, labor, fuel and all operating expenses. The maintenance has been much less and the labor less than with the steam engine had previously.

Bonds to the amount of $60,000 were sold for the installation of this plant. There is set aside $500 a month, which will pay the face of the bonds in ten years, and $250 a month for interest; so that it is expected to pay for the plant in ten years. The capacity of the plant is 300 kilowatts. The output varies from 900 to 1,500 kilowatt-hours a day, varying with the demand for motor load. The power-factor during the day is seventy per cent.

WEDNESDAY MORNING SESSION.

President Tait opened the Wednesday morning session and delivered his address, saying in part:

There has been a decided tendency during the past year for competitive electric companies in the same territory to consolidate, thereby effecting what is absolutely necessary for complete business and financial success in a public utility of any sort. It is only by the complete and absolute control of the electrical output in any community that a public service corporation can lower its production and distributing costs and thereby benefit the consumer as well as help itself.

Monopoly does not and can not successfully mean disregard for the public rights and welfare. The lighting company's responsibility increases in proportion to its complete and absolute monopoly of the lighting situation in its territory. The municipal ownership idea seems to be gradually falling behind. Each year is bringing the taxpayer to a better realization of the fact that "the public pays the bills."

Announcement was made by Secretary Gaskill that there was being held coincidently at the same hotel a convention of the Astronomical and Astrophysical Society of America, and suggested that the courtesies of the Ohio Electric Light Association be extended to them. The motion carried unanimously and the chair appointed T. D. Buckwell and L. Clifford Anderson as a special committee to wait upon Professor E. C. Pickering, president of the Astronomical and Astrophysical Society and communicate to him the action taken.

Professor Pickering, director of Harvard College Observatory, addressed the convention briefly and with evident gratification at the kindly reception and applause accorded him.

Professor Lord, professor of astronomy, Ohio State University, was also invited to address the association and returned his acknowledgments.

Secretary-Treasurer Gaskill submitted his report for the year, showing gross receipts of $1,815.56 and disbursements of $1,577.64. He congratulated the association upon the very active and successful work accomplished, characterizing the year as the most successful one in the history of the association.

C. R. McKay, of the Toledo Railways and Light Company, presented a paper on "Experience with Luminous Arc Lamps."

This paper describes the installation by the Toledo Railways and Light Company, in February, 1907, of some 547 luminous arc lamps of the General Electric type for series street lighting. This number has been steadily increased, until at the present time about 1,670 lamps are in regular service. The first few hundred lamps were operated from belt-driven Brush arc generators, which machines were gradually removed as the installation of twenty-five-cycle, constant-current transformers with mercury arc rectifiers and switchboard panels progressed. All the street lighting in Toledo is now effected by means of such lamps, which, for the most part, are spaced approximately 600 feet apart in the residence and outlying districts of the city, while in special cases the lamps are nearer together and set upon ornamental iron poles.

The lamps average from 320 to 324 watts per lamp, including line losses, as measured at the direct-current circuit terminals. The present 1,670 lamps, distributed over thirty-seven circuits, are trimmed by three trimmers, each provided with horse and buggy, and about one per cent of the lamps are in the shop as an average for adjustment or minor repairs.

Concerning the life of mercury arc rectifier tubes, there are many which have exceeded 2,000 hours life, and several have exceeded 3,000 hours life. The maximum recorded life of any tube up to June 1 was 3,589 hours and eight minutes. The average life of twenty-three tubes which burned out during May was 1,110 hours.

The chair called attention to the importance of arc-lamp efficiency and invited a full discussion, in the course of which Mr. Glosser (Marion) inquired if the lamps and tubes operated directly on twenty-five-cycle circuits without the use of frequency changers, to which Mr. McKay replied that no frequency changers are used in the operation of these lamps, the twenty-five-cycle current from the turbines being supplied to the constant-current transformers and delivered by them at the same frequency to the rectifier tubes, which in turn change the twenty-five-cycle current to a pulsating direct current.

Mr. McKay said that he doubted whether any motor-generator set would show up an efficiency much better than eighty-five per cent or eighty-six per cent at its full load; whereas the efficiency obtained by the rectifier system, as indicated by the tests given, is considerably higher than that; furthermore, it is to be borne in mind that by the use of constant-current transformers one is dispensing with any additional running machinery other than the generator itself. The attendance required in the operation of constant-current transformers with rectifiers is very little. In the station quoted, having some thirty-four sets, the work of handling the switchboard is done by exactly the same attendants who look after the other switchboard work in that station, which is a station of some 15,000 kilowatts capacity in the various systems. Practically none of their time is spent on the rectifier board except when they are plugging in circuits.

B. H. Gardner, of the Dayton Lighting Company, read a paper on "Best Ways and Means of Getting Out and Keeping Out Private Plants in Central Station Territory."

Mr. Gardner is of the belief that the primary fault to find with central stations is that too many of them still demand excessive rates for their service, these rates being based on quantity only, regardless of the quality of the load. There are still managers who think they can not go below some certain fixed price per kilowatt-hour which may represent average costs, while the truth is that they could afford to take on some kind of business at half the rates they have scheduled. For instance, there was recently a private plant purchased in a large city, although the parties wished to avoid the investment. The load would average from 200 to 300 kilowatts, and would be on from ten to fifteen hours per day. The central station refused to make any concession whatever, insisting on its lowest published net rate of three cents per kilowatt-hour, claiming it would lose money if the business were taken at a lower rate. This stand of the central station, combined with the fact that coal was cheap, explains why one private plant was installed.

To get out a private plant after the plant has once been put in operation is usually a very difficult task. The owner of the plant may be persuaded to close the plant down for a year, using the central station service during that year. It is advisable to take this business for the year's trial at a flat rate, this flat rate to be determined by the costs of the previous year. At the end of the year's test a long-term contract may be entered into at whatever rate the test shows the consumer is entitled to. There are not many people who will go back to a private plant after a year's use of central station service, provided, of course, this service is what it should be.

Mr. Elwell (Sidney) reported that in the case of several factories that were maintaining large steam plants and had their own dynamos he had had difficulty in securing their general lighting business, but had obtained some revenue for their night lighting. In a factory that had something like 200 lights wired up he would give it, say, a thirty or forty-light capacity, limiting the supply by fuse or circuit-breakers so as to avoid getting tied up to the extent of the full capacity, for which he would get no return.

W. C. Anderson reported that they had taken on a planing mill at a flat rate entirely off the heavy lighting hours and where the Edison main passed right by the place. An arrangement can be made with many planing mills not to use power during hours that artificial light is required. Mr. Messer reported that he furnished both power and light for the planing mills at Warren, and they used their refuse under their own boilers to make low-pressure steam for their dry kilns. He had furnished them power for four years.

Papers by J. F. Rothery, of the East Liverpool Traction and Light Company; C. A. Elliott, the Dayton Lighting Company, and H. Engle, Consolidated Gas and Electric Company, Youngstown, were read on the general subject of electric signs, outlining and other special uses of electricity as an adjunct to profitable central station work.

These papers were discussed as an entirety, and some interesting points brought out.

Mr. Buckwell (Toledo) referred to the introduction of motors for ventilating school buildings, an appreciated feature being that they are on from four o'clock in the morning until half-past three in the afternoon. When the school closes the motor is cut out.

Mr. Gaskill reported a similar installation in Greenville. When the schoolhouse was first built two gas engines were installed to operate two blowers, and they gave an unending amount of trouble, first because the janitor knew very little about their operation, second because it is difficult to get reliable small gas-engine units. The speaker, being on the board of education at the time, on tracing the matter up found that the repairs to the gas engine were running about $80 a year, and besides this a charge for gas. The board of education, after carefully considering the matter, decided to substitute electric motors. They are a strictly day load and average to the company about $10 a month. They have not caused the board of education a cent of expense for repairs since their installation.

In the absence of the author, the paper by F. H. Plaice, of Hastings, Mich., on "How Can We Best Increase Our Business?" was read by Secretary Gaskill.

E. D. Strickland, of Buffalo, Statesman-at-Large of the Rejuvenated Sons of Jove, addressed the meeting on the objects of the order.

Luncheon was served in the convention hall, after which the discussion of Mr. Plaice's paper was taken up.

WEDNESDAY AFTERNOON SESSION.

President Tait commented upon the statement by Mr. Plaice that "under the propaganda the addition is platted and the electric wires strung even before the streets are graded, so that when a house is built the service may be installed from the beginning." It may be a question whether the board of directors of the ordinary company would tolerate such an expenditure of money in advance of the business to that extent, but he believed that the majority of the central stations throughout Ohio are too backward in installing service for those who want it. It is certainly detrimental to install service where one is not going to get an adequate return; but he believed that occasionally it is necessary to stretch a point in order to get new business, and it is always possible to find out certainly just how much line one can afford to build, and if necessary to increase the minimum service charge for a year or two till the place grows up, with the understanding that as increasing numbers of the people connect themselves with the circuit the minimum charge will be reduced in proportion.

W. P. Engel related an instance where a line was erected to outlying territory, the consumer agreeing to pay $200 of the expense of erecting the line, with the understanding that as further connections were made he would be given a rebate; and under a flat rate of $1 minimum and ten cents meter charge per 1,000 watts the result was that in less than a year sufficient houses were connected to enable the company to make a complete refund to the original consumer.

Edward F. Gwynn, of the Delaware Electric Light and Power Company, presented the first of two papers on this question, "Should Central Stations Do Wiring" This was followed by a contribution on the same subject by C. C. Custer, of the Miami Light, Heat and Power Company, of Piqua, Ohio.

Mr. Gwynn, speaking from his own experience and especially in smaller cities of, say, 15,000 population and under, states that his answer to the question, Should central stations do wiring? would be, "Yes." He believes that this is necessary to properly serve and protect the company's patrons. Cities of this size (15,000 population) can support but one first-class wiring and construction establishment, and some cities can not do this. It should be the duty of the central station to look after all new buildings and see that the electrical installation is not being overlooked nor neglected. He believes that in small cities the average citizen has more confidence in the central station and prefers to deal with it rather than with a supply house or contractor.

Mr. Custer is of the opinion that the function of the central station is to generate and distribute electrical energy. It is to the central station's interest that house wiring be well done and the wiring business pushed, but this does not mean that the work must be done by the central station, nor that when so done it will be better wiring. It seems to him that this is a field where the central station should be a co-operator instead of a participator. It is possible to get good wiring done by private contractors, and such contractors should have the moral support and co-operation of the central station. When sure of this support he believes it is generally possible to get a sufficient number of responsible private wiremen to enter the field.

W. P. Engel was strongly of the opinion that central stations, whether large or small, should do wiring and should have a trouble man to look after every little detail of residence, store or factory, and in this way give more prompt service and eliminate kicks that this, that and the other was going wrong. He would charge the consumer for every renewal and every supply part used for repair, but there should be no time charge made in the bill.

Mr. Adams (Lorain) quoted the experience of the gas company in the introduction of gas stoves and the fact that by their going into the plumbing business they had so increased the use of gas stoves that they were now selling thirty per cent of their output for heating and cooking. He inquired why the same policy should not be followed with regard to electric wiring.

Mr. Selig (Mt. Vernon) reminded the convention that last year he had expressed himself in favor of central stations withdrawing from the wiring business and turning it over entirely to the contractors. A year's observation had further confirmed him in this opinion. In this way the central station enlists the assistance of the contractor, which often proves valuable.

Mr. Turner stated that in Cleveland about two years ago they initiated an instalment plan of payments for wiring, the wiring being turned over to certain contractors. The first year some 500 houses were wired, but the company was not satisfied with the general results, and had adopted another plan which gave promise of being more successful, and up to this time about 1,000 houses have been wired under it. It accomplishes results and at the same time keeps the central station out of any liability or responsibility, either legal or moral. The company solicits the wiring of houses under a flat price per outlet. The contract is then turned over to any reliable wiring contractor who will work under this plan, *viz.*, that he must undertake any houses turned over to him whether he makes or loses money on them, and his price for wiring can not exceed the printed schedule of flat rates at so much per outlet. The company gives the consumer credit on his electric light bill for fifteen per cent of the cost of wiring and fixtures up to a total of $15; that is, fifteen per cent on his total bill not exceeding $100 worth of fixtures and wiring. The fixture houses agree to sell fixtures also on the instalment plan of payment. The plan has been working out very successfully during the past year, and the incentive for the man wiring houses to do soliciting is that he turns the contracts over for the wiring of houses on a pro rata basis as to the number turned over to us that he has solicited.

J. S. Codman, of Boston, Mass., presented his paper on "Illuminating Engineering."

Mr. Codman believes that in co-operation with customers there is, at least in the lighting field, a good opportunity to bring down the cost, since the waste by customers, not only in converting electrical energy into light, but also in the use of the light itself, is something prodigious. This continual waste, unrealized by customers, leads to the impression that electric lighting is more expensive than is actually the case. The result is that many are afraid even to try it, and the growth of the business is stunted. One of the principal objects of the science of illuminating engineering is to prevent, or at least check, this waste, and some knowledge of its principles is of great value to those connected with the central station business. Much electricity is wasted by customers through the use of cheap lamps of low efficiency. This can best be remedied by the adoption of the wise policy of furnishing lamp renewals to customers, either free or at less than the market price. Another prolific cause of waste is the use of dirty lamps. The use of an unnecessary number of lamps is still another form of waste. Another cause, also common in residences, is the failure to make it easy to turn the lights on and off. There are other ways in which light is wasted which are not so obvious, and to overcome which some knowledge of illuminating engineering principles is necessary.

Professor F. C. Caldwell, of the Ohio State University, discussed in an able manner the leading points in Mr. Codman's paper.

D. L. Gaskill, of the Greenville Electric Light and Power Company, presented a report on the experience of central stations with tungsten lamps.

This paper is a recapitulation of the experience of a number of central stations using tungsten lamps for the last six months of a year. From this summary the conclusion is arrived at that the tungsten lamp has been in use for too short a time to judge fully as to its adaptability for general use. The price at present charged is exorbitant and will prevent its coming into general use unless reduced. The life of the lamp is shorter than that claimed by the manufacturers, or it does not permit of a wide range of conditions such as must be met by any lamp in general use. The brilliancy and the economy of the lamp are particularly good. While fragile, it has borne shipment with fairly good results. Discoloring of the lamps has not been bad, nor has such change affected the quality of the light. It is a valuable adjunct in meeting competition, and, where installed in the proper manner, gives excellent results from the illuminating standpoint. The larger units, as now made, are most desirable. Until the price is reduced the most satisfactory method of disposing of them to the consumers is through the supply houses.

George C. Osborn said that this report was convincing of the fact that the central stations in Ohio are enthusiastic users of the tungsten lamp. Considering the five installations as a whole and not in part, there were twenty-six lamps installed, and of this number eight were shown to have burned out, and eighteen, or seventy per cent of the total mentioned, are still burning. The average life of the early burned out lamps equals 397 hours; and the remaining eighteen, or seventy per cent, were still burning at the end of 382 hours. The total amount paid for the tungsten lamps, considering them at a price of $1.65, would aggregate $42.90; the total that would have been paid for carbon lamps would be $13.28, showing a differential of additional cost for tungsten lamps of $29.62. Five new installations were obtained involving the displacement of gas or gasolene at a cost to the central station at the present time of $6.27, eliminating the rental which will accrue from the seventy per cent of the lamps still on circuit. The report indicates that the installations were used on an average of four hours per day, and at a rate of ten cents per kilowatt-hour the income thus far received has been $100. Surely this is making one blade of grass grow where none grew before. Even with the apparent short-life showing made by this central station it can thus be seen that the use of tungsten lamps was of great benefit.

A successful method of satisfying a prospective customer on the life of tungsten lamps is to show him what the minimum life is that the lamp will pay for itself as compared with an installation of the same candle-power obtained with carbon-filament lamps on free renewal basis. In the above report, where the price of the lamp is given at $1.65 the 100-watt tungsten lamp pays for itself in current saved on a ten-cents-per-kilowatt-hour rate in ninety-two hours; and, therefore, in the average life shown above every lamp had paid for itself four times over, and seventy per cent were still in service.

THURSDAY MORNING SESSION.

Secretary Gaskill announced the banquet for Thursday evening, stating that it was free to all, whether active or associate members or guests. He urged a full attendance, as elaborate preparation had been made to make the occasion an interesting and entertaining one.

The nominating committee submitted their report, and at the suggestion of Secretary Gaskill action on same was laid over until just before the noon adjournment, in order that all might have opportunity to consider the nominations made. Later on in the session the report was taken from the table and unanimously adopted, electing the following as officers for the ensuing year:

President, C. R. McKay, Toledo.

Vice-president, J. C. Rothery, East Liverpool.

Secretary-treasurer, D. L. Gaskill, Greenville.

Executive Committee—F. M. Tait, chairman, Dayton; W. P. Engel, Defiance; M. E. Turner, Cleveland; W. F. Hubbell, Wauseon; L. G. White, Columbus.

Advisory Committee—Samuel Scovil, chairman, Cleveland; F. M. Tait, Dayton; D. L. Gaskill, Greenville.

Publicity Committee—E. L. Booth, chairman, Bellaire; W. A. Wolls, Columbus; W. C. Anderson, Canton.

Finance Committee—T. D. Buckwell, chairman, Toledo; L. C. Anderson, Franklin; T. D. Elwell, Sidney.

Membership Committee—W. J. Hanley, chairman, Cleveland; C. B. Rodgers, Tiffin; H. H. Cudmore, Cleveland; G. E. Miller, Cleveland; C. M. Lott, Hicksville.

The chair announced that the discussion on the tungsten lamp would be resumed at this time and called upon F. W. Willcox, of the General Electric Company, Harrison, N. J., to address the convention.

Mr. Willcox said the central station interests have cause for congratulation that the tungsten lamp is available. There are two features of this lamp that should cause all central station men to rejoice; one is that the efficiency obtained has been secured with a simple form of incandescent lamp. This has not been the case oftentimes in the evolution of a science or device; the tendency is generally to run to greater complication. That means a great deal of saving in investment and writing off of old apparatus, because the lamp simply replaces itself in the ordinary course of renewals, and therefore there is no antiquation. The report heard yesterday is also cause for congratulation as showing that in its inception, the lamp only having been six months in service, as shown by these reports, has acquitted itself so well. We have never had in the history of any developments any lamp that has shown the promise and performance that the tungsten lamp has. Other developments, such as the Gem, tantalum and improvements in the arc lamps have required much longer time and caused a great deal more complaint and dissatisfaction before finally arriving at satisfactory condition. It is now up to the central station to adopt some policy that will insure the lamps being introduced and the consumers given the benefit of it. As far as he can judge it seems that experience so far indicates that the most satisfactory policy will be a monthly maintenance charge for the lamp, which avoids the user having to pay full price of the lamp whenever one burns out.

The twenty-five-watt tantalum lamp should be seriously considered by central stations. This lamp is reasonable in price and, while it has not as large candle-power as the ordinary sixteen candle-power, yet, considering brilliancy, it is fully as satisfactory a lamp as the sixteen-candle-power. It is serviceable and more handy and durable than the tungsten lamp, and in conjunction with the tungsten lamp should find wide use in the improved economy which renders these new lamps necessary. The tantalum lamp has been materially improved in life since its introduction, giving a life on direct current well over 1,000 hours, and on alternating current of sixty cycles or less it is found that the light is about two-thirds of what it is on the direct current. It is reported from abroad that the German manufacturers are at present doing a larger business in tantalum lamps than in tungsten.

J. R. Cravath said that in regard to a question about the equivalent lighting value of the 100-watt tungsten lamps and gas arcs, he had occasion to figure out the probable relative value from theoretical considerations and arrived at the conclusion that under most conditions two 100-watt lamps would easily replace the ordinary gas arc. It would not do it where the gas arc was always maintained under ideal laboratory conditions, but we all know they never are maintained that way; it is a physical impossibility. Unless they are adjusted just right to give the maximum candle-power from hour to hour it can be pretty safely figured that two 100-watt lamps with reflectors will deliver as much useful light in the store as one gas arc.

W. C. Anderson, of Canton, said that in the matter of meeting gas cost, where there is natural gas competition it is absolutely an impossibility to meet the cost of gas; but customers are very glad to pay more money, not only fifty per cent more, but two or three times as much to get a satisfactory light. That has been proven very well, not with the tungsten lamp, because that has only been available a short time, but with other illuminants, the direct-current enclosed arc lamp and the Nernst lamp and the Gem lamp.

President Tait asked Mr. Willcox if it was fair to expect that the tungsten lamp will ever reach a development such that the price will go down proportionately as the price decreased on the carbon-filament lamp? For instance, the latter was bought years ago for $1.25 and they gradually came down to fourteen or fifteen cents during the course of five or ten years.

Mr. Willcox replied that there are so many factors involved that one can not give a definite answer, but from the present outlook it does not seem as if it could; yet that does not mean that something may not develop in the way of a cheapening process that one can not foresee now which will make it possible to bring that lamp relatively as low in cost as the carbon; but central stations must remember that we are dealing with a lamp that runs on one and one-quarter watts per candle instead of three to three and one-half watts per candle, and therefore even at the same cost it is going to be three times as high. Even at the same cost for equal candle-power the tungsten lamp renewal cost per kilowatt-hour will of necessity be three times as high as that of the carbon lamp.

Mr. Osborn said that those central stations that are selling the lamp at a high price are just as aggressive and getting just as many customers as those that are selling cheaper. The subject of rental basis is one that can be scaled down as low as one cares to make it, but the actual selling price of the lamp, if it was reduced in any case ten or fifteen per cent, would not affect its sale. If a reduction in price comes it will be better for a central station to pocket that difference and perhaps be more liberal on the question of early burnouts or trial installations, or a liberal policy generally in handling the proposition rather than to make a corresponding reduction in price which would hardly count for anything. The question of what the life is going to be is often asked; what the minimum life is in which the lamp will pay for itself. A lamp that will cost $1.80 will pay for itself ten times in 1,000 hours, so that it pays for itself at the end of 100 hours' use.

Mr. Gardner said that the Dayton Lighting Company charges a rental for one 100-watt tungsten lamp of twenty cents a month regardless of the number of hours that it may be used. If a man only burns his lamps about two hours a day they would actually get more, taking a basis of 1,000 hours, than it would cost to renew; in other words he would pay for his own renewals. If a man uses his lamps three and one-half hours a day he pays about as much as it costs to renew them on a basis of 1,000 hours. If he burns them ten hours a day it will cost the company about two cents per kilowatt-hour to renew those lamps, and at the same time it is getting eleven cents per kilowatt-hour for ten hours a day service. Twenty-five cents per lamp per month would assure a little better return; burning for five hours per day it would not cost anything for renewals.

H. M. Browne, of the Nernst Lamp Company, described the new Westinghouse Nernst units which are being placed on the market. These new units of single-glower type have screw base renewal and are made in sixty-six-watt, 110-watt and 132-watt sizes, both alternating-current and direct-current, 110 volts; eighty-eight-watt, 110-watt and 132-watt, 220 volts. The efficiency of the new unit on single-glower lamps will range from 1.2 to 1.4 watts per candle, with regular alabaster globes; on the multiple-glower, from 1 to 1.25 watts per candle, depending on the size of the lamp. On the holder of the multiple-glower type lamps we have a wafer heater. This wafer has a longer average life than a heater tube and costs very much less.

D. L. Gaskill read a paper on "Some of the Causes of Failure in Municipal Lighting Stations."

L. Clifford Anderson, of the Franklin Electric Light Company, read a paper on "Grounded Alternating-Current Secondaries."

E. F. Creighton, of the General Electric Company, delivered a very interesting address on the subject of protection from lightning, describing the many measurements made to determine the phenomena and effect of the current induced by lightning discharges and bringing out the main features of the new types of lightning protective devices which have been placed on the market.

After discussion and some routine business a recess was taken until 2.15 P. M., when the paper entitled "Gas and Gasolene Lighting Competition and Best Ways to Meet It" was read by Fred Leslie, of the Muncie (Ind.) Electric Light Company.

There was some further desultory discussion and the convention adjourned to meet when and where it may hereafter be determined by the executive committee.

One of the interesting events of the convention not upon the regular programme was the Rejuvenation of the Sons of Jove on Wednesday evening. The initiation was in charge of Jupiter H. H. Cudmore, of Cleveland, Ohio, and Statesman-at-Large E. D. Strickland, of Buffalo, N. Y. The Sons of Jove now number over 1,700. The initiates were: Charles L. Bogner, Cleveland Electrical Supply Company, Cleveland, Ohio; William A. Baker, American Electrical Heater Company, Detroit, Mich; William R. Collins, New York & Ohio Company, Warren, Ohio; F. R. DuGuay, Erner Electric Company, Cleveland, Ohio; H. O. Dutter, Bucyrus Gas and Electric Company, Bucyrus, Ohio; F. L. Finch, Union Electric Company, Pittsburg, Pa.; Warner Jones, Cleveland Electrical Supply Company, Cleveland, Ohio; T. J. Smith, New Lexington Electric Company, New Lexington, Ohio; E. L. Van Winkle, Post-Glover Electric Company, Cincinnati, Ohio; F. A. Williams, chief engineer Hotel Victory, Put-in-Bay, Ohio.

The annual meeting of the Sons of Jove will be held in Buffalo, N. Y., on October 15 and 16, 1908.

The entertainment committee arranged a number of interesting events for the attending ladies and delegates. Dances were held on Tuesday and Wednesday evenings; a progressive euchre party and a bowling tournament for the ladies on Thursday morning, and a vaudeville performance on Thursday evening, with volunteer talent. The ladies were also conducted on a trip through the caves. Music and songs were rendered on Wednesday evening by a colored quartette.

The following companies made exhibits:

Allis-Chalmers Company; represented by F. C. Colwell, Cincinnati, and S. Wolff, Cleveland, Ohio; exhibiting polyphase and direct-current motors, autostarter and transformer, rotating part of steam turbine showing internal construction.

Diamond Rubber Company; Edwin Williams, sales manager; large-sized National Electric Code cables; issued an attractive postal card.

Duncan Electric Manufacturing Company; Adrian Tobias, sales manager; showed a line of integrating watt and test meters.

The General Electric Company was represented by H. C. Houck, C. R. Wallis, Cincinnati; W. J. Hanley, H. B. Goodloe, Cleveland; L. R. Dunkle, Columbus; G. H. Stickney, Lynn, Mass.; George C. Osborn, F. W. Willcox, Harrison, N. J.; E. F. Creighton, R. E. Russell, Schenectady, N. Y. The exhibit especially emphasized the latest developments in tungsten diffusers. There was an interesting layout of tungsten lamps for church installation, showing fixtures with units grouped in an artistic way; also photographs of other unique fixture designs. Another feature was a new lamp-testing watt indicator for the purpose of making ocular demonstration to prospective customers of the relative watt consumption of metallic and carbon-filament lamps.

The Holophane Company; A. C. F. Keleher, New York; J. S. Codman, Boston, Mass.; line of new prismatic reflectors, giving ten per cent increase of candle-power; concentrators used for window lighting with very high ceilings.

The Ideal Electric and Manufacturing Company; Clarence E. Delafield, S. E. Huenerfauth, Mansfield, Ohio; new single-phase motor.

H. W. Johns-Manville Company; R. R. Braggins, manager electrical department, Cleveland, Ohio; exhibiting insulating material, fuse devices, "Linolite," service and subway boxes, friction tape, etc.

National Metal Molding Company; V. F. Gates, Cleveland, Ohio; metal molding.

Nernst Lamp Company; Max Harris, Pittsburg, Pa.; H. M. Browne, manager, Detroit, Mich.; showing new screw burner Westinghouse-Nernst lamp, made in four sizes, from fifty to 125 candle-power.

New York & Ohio Company; William R. Collins, Warren, Ohio; advertising literature.

The Sterling Electrical Manufacturing Company; W. F. Benedict, J. T. Donahue, Warren, Ohio; presented all comers with souvenir rules, tape measures, handsome celluloid blotting pads, etc.

Wagner Electric Manufacturing Company; Thomas T. Richards, St. Louis, Mo.; Dean Emerson and Paul Sentman, Cincinnati; switchboard instruments, etc.

Western Electric Company; George H. Porter, sales department, Chicago, Ill.; F. M. Shely, Cincinnati; arc lamps and Sunbeam tungsten lamps.

Westinghouse Electric and Manufacturing Company; J. W. Schrantz, Cincinnati; C. E. Miller, R. D. Nye, George S. Vail, Cleveland; H. H. Hughes, Columbus; Charles H. Davis, L. A. Starrett, S. A. Fletcher, J. O. Little, W. B. Wilkinson, Pittsburg, Pa.; fan motors of various sizes, electric irons and heating apparatus, glue pots, meters, etc.

The Ambos-Cudmore Company; H. H. Cudmore, Cleveland, Ohio; Weston Electrical Instrument Company apparatus, Eclipse voltmeters and ammeters, oil switch, Condit oil circuit-breakers, flexible conduit, etc.

The Adams-Bagnall Electric Company; represented by A. J. Mitchell, Cleveland, Ohio, who distributed court-plaster.

The Sanitary Pump Company; duplex reciprocating power pump operated by electric motor, manufactured for pressures up to 150 pounds, and in sizes up to 1,000 gallons per hour.

The Pittsburgh Transformer Company; ten-kilowatt Pittsburgh transformer, with silico-vanadium steel core.

Invincible Electric Renovator Sales Company, Cleveland; apparatus in operation sweeping the carpet in the hotel lobby.

Among other manufacturers and supply and material men in attendance were the following: American Electrical Heater Company; W. A. Baker, B. H. Scranton. American Electrical Works. American Shipbuilding Company, J. E. Ginn. Benjamin Electric Manufacturing Company; H. E. Watson. The F. Bissell Company; Fred Bissell, Frank M. Knierim, A. J. Gray, Joseph E. Lockwood. Bryan-Marsh Company; Fred W. Godfrey. Central Electric Company; W. D. Dunsmore. Cleveland Electrical Supply Company; L. Greisser, sales manager; Warner Jones. Doubleday-Hill Electric Company; Elliott Reynolds, W. D. Shaler. S. K. Elliott Electrical Company; S. K. Elliott, C. P. Billings. Electrical Appliance Company; F. J. Anderson. Erner Electric Company; F. R. DuGuay. Erner & Hopkins Company; H. B. Rogers, William A. Hopkins. Fort Wayne Electric Works; George B. Edgar, A. A. Serva. Federal Electric Company; James M. Gilchrist. Globe Electric Company; J. E. Swisher, A. B. Flagg. Hall Gas Engine Company; Marvin E. Hall. F. D. Lawrence Electric Company; Charles E. Kuntz. McKeever Electric Company. W. N. Matthews & Brother; V. L. Crawford. W. G. Nagel Electric Company; Harry E. Adams, A. I. Carney. National Carbon Company; N. C. Cotabish, A. G. Summerell, A. B. Pyke. Post-Glover Electric Company; Edwin L. Van Winkle. Robertson Electric Company; E. D. Strickland, manager publicity department. Standard Underground Cable Company; Le Loyne L. Parkinson. A. L. Swett Electric Light and Power Company; Arthur J. Howard, manager. Toledo Electric Company; Charles E. Yost. Union Electric Company.

French Cable Company Fined in Venezuela.

The Civil Court of the First Instance at Caracas, Venezuela, has handed down a judgment declaring the French Cable Company guilty of complicity in the Matos revolution against President Castro. The company is condemned to pay damages of nearly $5,000,000 and a further amount to be assessed later by experts. The company will probably appeal.

THE TEST-METER METHOD OF TESTING SERVICE METERS—IV.

BY JOSEPH B. BAKER.

COMMERCIAL TEST METERS OF THE MOWBRAY TYPE—THE GENERAL ELECTRIC AND FORT WAYNE TEST METERS.

It should be stated at the outset that by "test meter of the Mowbray type" is meant any specially constructed test meter of the type described in former articles having a number of field coils giving equal torque for any given percentage of full load on each coil, thereby enabling the meter to be used for testing through a wide range with constant high accuracy. Test meters so designed and used are to be distinguished from "portable standard" meters, either of ordinary construction and fixed capacity, as employed in the early days of meter testing, or of special construction and variable capacity, as exemplified in the Westinghouse portable standard integrating wattmeter. In using the term "Mowbray type" the author does not mean to pronounce upon the matter of priority of invention, patent rights, etc.

Fig. 7.—Thomson High-Torque Induction Test Meter.

ADVANTAGES AND COMMON FEATURES.

The General Electric Company and the Fort Wayne Electric Works are now putting out alternating-current test meters of the Mowbray type, which will be described in the following. Only the individual features of each will be dwelt upon in text and illustrations. For general discussion of the test meter the reader is referred to the matter on preceding pages.

In introduction, it may be well to rehearse very briefly the need which the test meter fulfils in the testing of consumers' meters, and the advantages claimed for the Mowbray type, the fundamental features of design which must be incorporated to obtain these advantages, and the features of operation common to all makes.

In regard to the need filled by the test meter, it is only necessary to call attention to the enormous increase in the number of consumers' meters in service and the higher standard of accuracy in the measurement of electric energy which is now insisted upon in modern central station companies.

While the General Electric and Fort Wayne test meters (see Fig. 7 to Fig. 15) differ in details of design and features of operation, certain fundamental features of design are common to both.

The most important is the composite field winding for obtaining a wide range of operation at maximum precision by securing a high torque in the moving element, constant for every field winding—*i. e.*, the same for any given percentage of full load on one winding as for the same percentage of full load on every other winding. Thus it is claimed for one of these test meters that the torque when using the smallest coil with one ampere passing is equal to that produced by using the largest coil with twenty amperes. The disposition and range of the composite winding and the method of effecting its various connections in order to adapt the test meter to the testing of different capacities of consumers' meters, differ between the two manufacturers.

Another important feature is the electrical method of starting and stopping the test meter—by a switch in the potential circuit.

The use of a register for counting the revolutions of the test meter against the revolutions of the meter under test is the outgrowth of the simple disc and pointer of the earlier test meters. While differing in actual design, the register is in both cases of simple (horizontal) form, with three dials, giving sufficient range of registration for practical testing purposes. It is located in the top of the test meter, with good-sized dials adapted for easy reading. The main dial is divided into hundredths, and its pointer is fixed directly on the meter shaft.

Portability of the test meter and accessibility of its parts have been sought. In both makes a neat carrying case, with lock and strap, are provided, and considerable ingenuity has been exercised to facilitate inspection and repairs. The arrangement of keeping the moving element out of contact with the jewel in transportation is regarded as a necessary feature of the test meter as a portable piece of apparatus. A simple and positive "locking device," operated by a thumbscrew, is employed.

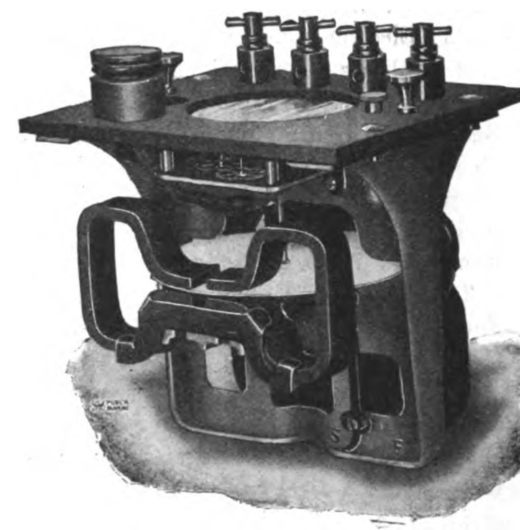

Fig. 8.—Working Parts of Thomson High-Torque Induction Test Meter.

In regard to the bearings, the manufacturers have realized the importance of providing minimum friction and maximum durability in order to maintain the maximum ratio of torque to mechanical friction. Both the General Electric and the Fort Wayne test meters of the present day are equipped with spring-supported cup-diamond jewel step bearings and removable pivots. The top bearings and shaft construction, however, differ in the two makes. The usual care in providing damping magnets of the greatest strength consistent with permanency, and a moving element of minimum weight are exercised in these test meters as in other modern commercial meters.

Certain other features of the several

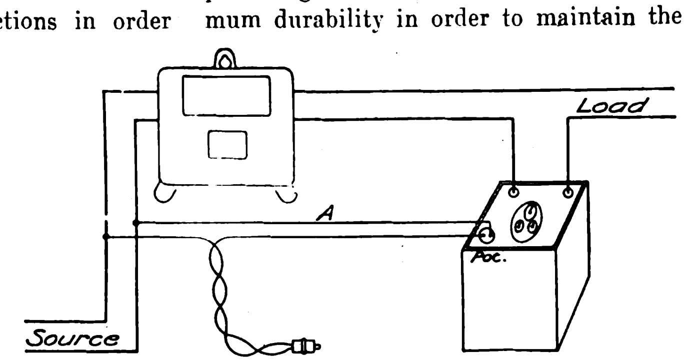

Fig. 9.—Connections in Using Thomson High-Torque Induction Test Meter.

commercial test meters, as meters, are common to all makes.

The operation of both the General Electric and Fort Wayne test meters is the same and may be described briefly as follows:[1]

The test meter should be placed convenient to the consumer's meter and the rotating element lowered onto the jewel. After making the proper connections for test meter and consumer's meter and ascertaining by temporarily starting the test meter (by closing the switch, which is in the potential lead for alternating-current meters) that its disc rotates in the counter clockwise direction, a reading of the register should be taken. Or, the main pointer may be brought to zero by manipulating the switch. The test meter should be started for the test simultaneously with the beginning of the count of the revolutions of the consumer's meter, and stopped after the desired number of revolutions has been taken. The register should then be read again, and the difference between the readings will give the total number of revolutions. The watt-hours registered by each meter are simply the product—quickly obtained on the slide rule—of its respective revolutions and calibrating constant. Since the constant is the watt-hours registered per revolution, the relative accuracy of the meter under test is shown by the ratio of the watt-hours registered by the two meters. A sufficient number of revolutions should be taken to make negligible any error in reading the test meter. As already stated, after the test has once been started it need not be stopped until the desired number of revolutions has been taken, as any change in the external circuit affects both meter under test and the test meter equally.

Fig. 10.—Calibrator with Cover Open.

In checking the test meter the same rules are followed as in testing standard meters, with the possible exception of the formula, which, with the constants usually furnished with the test meter by the manufacturer, becomes:

$$\frac{3600 \times \text{revolutions} \times \text{calibrating constant}}{\text{seconds}}$$

= watts registered by test meter.

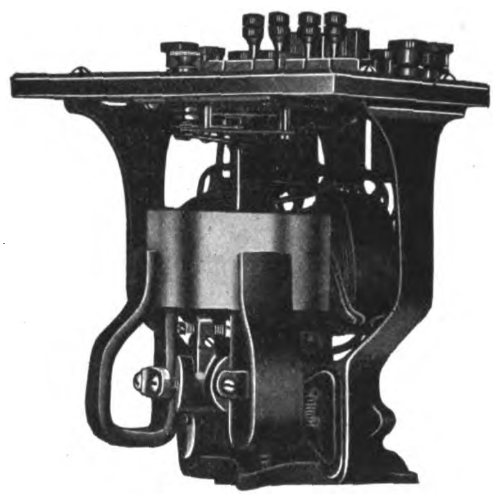

Fig. 11.—Calibrator Removed from Case.

Calibration of the test meter is most readily done in the test room by the indicating-instrument and stop-watch method, the necessary adjustments being made in the same way as in the regular consumers' meters of each manufacturer; any special devices are described.

GENERAL ELECTRIC COMPANY TEST METER.

The Thomson high-torque induction test meter, type IB-2, manufactured by the General Electric Company (Fig. 7 to Fig. 9), is designed for testing 110-volt alternating-current meters of three-ampere to twenty-five-ampere normal capacity.

Special features of this test meter, described in detail below, are the simplicity of the connections to the test meter and of the general design, extremely high torque, astatic magnet system, and special calibrating devices.

The test meter is contained in a case nine and one-half inches by eight inches by seven inches, with hinged cover. The register has three dials and the ratio between gears is ten to one, so that the second dial reads in units and the third in tens of revolutions. The units and tens dials are placed inside the main dial. The standard three-dial register permits a three-minute test at full load to be made, as the full-load speed of the test meter is lower than thirty-five revolutions per minute. No current leads for connections between test meter and consumer's wiring are provided, but the potential circuit is wired to a receptacle in the top plate of the test meter, and a flexible lead is provided having a plug at one end for inserting into the receptable and a pendent snap switch near the other end by means of which the potential circuit may be closed and opened from a distance.

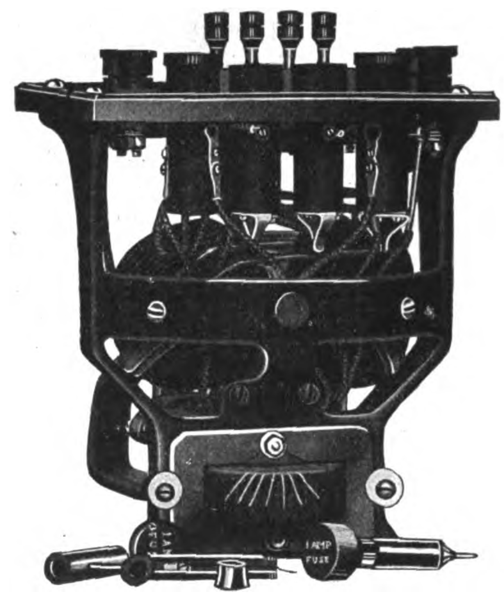

Fig. 12.—Back View of Calibrator Removed from Case.

As shown in Fig. 7 and Fig. 8, the test meter is assembled on a central frame hung from the plate which forms the top of the test meter when the cover of the case is opened. The register dials are in the middle, and along the rear edge are four heavy binding-posts for the current connections. The binding-posts are of simple and rugged pattern, adapted for making "solid connections" with ordinary wire leads. A little to the right of the dials is the thumbscrew for the locking device, and at the left is the receptacle for the potential plug. By means of a pair of buttons, one at each side of the top plate, the test meter may be lifted bodily from its case to make it accessible for calibration or repairs. As shown in Fig. 8, when removed from the case the test meter may be set down resting stably, in a vertical position, on the botton rib of the frame casting. The single-potential winding with which the test meter is equipped may be used on voltages ranging ten per cent on either side of normal (110

[1] The appropriate current coil—i. e., the coil of capacity nearest approximating the load under which the consumer's meter is being tested—should be connected in series with, and between, the meter under test and the load, and the potential coil should be connected across the line between the mains and the meter under test.

volts). There are three current coils, one end of each being connected to a common binding-post, and the other ends to each of the three remaining current binding-posts, marked with the respective ampere capacities of the coils, one, ten and twenty.

In general construction, the Thomson high-torque induction test meter compares well with any make of test meter, as may be seen without need of lengthy description, by an inspection of Fig. 8. Calibrating on full load is effected by loosening the two clamping screws that hold the magnet shoe and then moving the magnets bodily. This illustration shows the general accessibility of the parts. Light-load adjustment is obtained in the usual way by moving a lever at the bottom of the test meter to the right or left, thereby shifting a small rectangular conductor in the space between the potential winding and the disc; the distortion of the flux thus produced accomplishing the desired result without affecting the full-load calibration. The top bearing is a simple hole drilled in the bottom plate of the register.

It is stated by the maker of this test meter that it possesses a constant accuracy throughout a range of 200 to 1, *i. e.*, from a two-kilowatt load down to a ten-

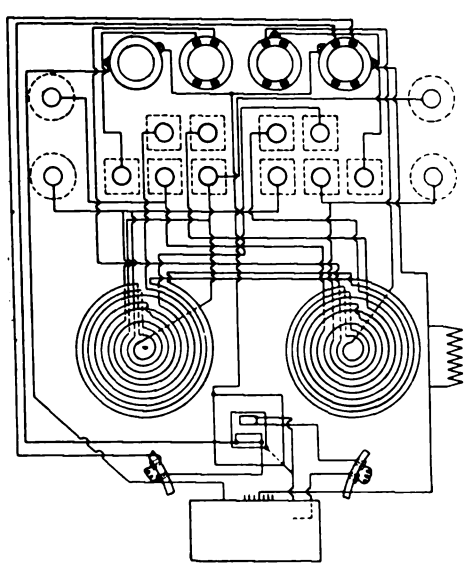

FIG. 14.—WIRING OF CURRENT-COIL SECTION TO PLUG SWITCH.

watt load, and that negligible error is introduced by ten per cent changes in voltage or frequency.

The correct connections of the Thomson high-torque induction test meter for testing a regular two-wire, three to twenty-five-ampere type I Thomson high-torque induction meter are shown in Fig. 9. The testing procedure is the same as already described in the general discussion of commercial test meters of the "Mowbray type."

THE FORT WAYNE ELECTRIC WORKS TEST METER.

The Fort Wayne type of test meter, the portable wattmeter calibrator, type

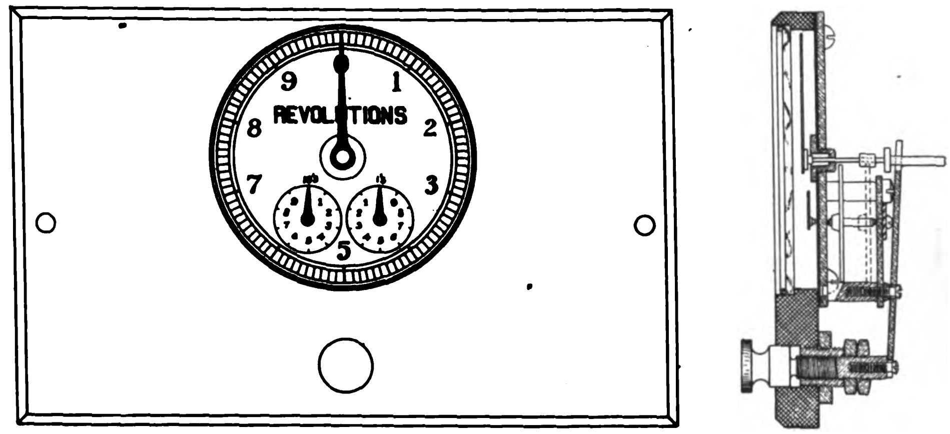

FIG. 13.—REGISTER MOVEMENT AND DIAL OF CALIBRATOR.

KM-1, manufactured by the Fort Wayne Electric Works, is one of the most recent additions to the growing family of test meters.

This "calibrator," which is shown in the general views, Fig. 10 to Fig. 12, is designed for testing alternating-current meters, covering the range of most 110-volt and 220-volt meters in service on two-wire and three-wire circuits from light load to full load. Special features of the calibrator, described in detail below, are its wide range, the plug-switch method of cutting in the different field-winding combinations, the provision of fuses to protect the one-ampere field winding from accidental overloads, the use of the Fort Wayne type of "cap" instead of the flat disc that is employed in meters of other types, and the general accessibility of the calibrator.

The calibrator is contained in a mahogany carrying case eight inches by eight inches by ten and three-quarters inches. The register (Fig. 10 and Fig. 13) is in the front section of the top plate, and consists of a main dial two and three-quarters inches in diameter, and two smaller ones within the main dial. The ratio between gears is ten to one, so that the second dial reads in units and the third in tens of revolutions. Flexible current and potential leads are provided, the former being a four-conductor cord with punched meter terminals at one end and cable connectors at the other end, all stamped with distinguishing letters to facilitate the making of correct connections with the calibrator and the consumer's wiring, respectively; and the latter a two-conductor cord with a pendent snap switch cut in on it for closing and opening the potential circuit of the meter, and having plugs at one end for connection to the potential receptacles on the meter and spring clips at the other end for connecting to the line. One of the cable connectors of the current leads and one of the line connectors of the potential leads are stamped plus (or minus), to facilitate the correct poling of the calibrator.

Referring to the illustrations, the calibrator is fitted with a hard-rubber top

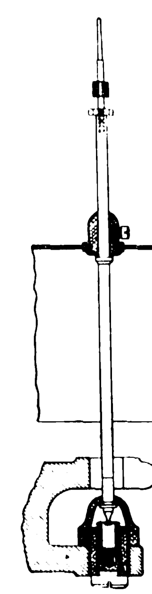

FIG. 15.—STEP-SHAFT BEARINGS.

plate, in two sections, which contains all of the devices used in the operation of the calibrator in the testing of meters.

The front section, which contains the register, as already described, is supported by the frame of the meter, which in turn is supported on the bottom of the carrying case. Directly in front of the register is located a knurled thumbscrew for operating the "locking device." Turning this screw to the right raises the rotating element and locks it firmly for transportation, out of contact with the jewel, and turning the screw to the left lowers the rotating element onto the jewel. The rear section which is supported by the frame, like the front section, contains the four current binding-posts (two at each end of the plate) and the two potential receptacles (in the middle of the plate) one for use on 110 volts and the other for use on 220 volts, both provided with caps to prevent dust from entering the calibrator when the plug of the potential lead is removed. On each side of the potential receptacles is a receptacle for a one-ampere fuse, consisting of a piece of ordinary fuse wire mounted in a fuse chamber of special design. The front middle part of the plate is occupied by the plug switch which is used for effecting the various combinations of the two current coils with which the calibrator is equipped to give the latter the necessary range of capacity. The current coils are wound in sections which may be connected by means of the plug switch in series, series parallel, or parallel in conjunction with the cable connectors on the current leads. The wiring of the current-coil sections to the plug switch is shown in Fig. 14. The windings selected as most suitable for meter testing are of one, two, five, ten and twenty-ampere and 110 and 220-volt capacity. With these windings meters up to and including twenty-five amperes, two wires, either 110 or 220 volts, and up to and including twelve and one-half amperes, three wires, 220 volts, may be tested.

The top and step-shaft bearings are shown in Fig. 13 and Fig. 15. The top bearing is located in the top plate of the register and is easily accessible by removing the glass, which is held in place by a spring brass ring and the pointer over the large dial. The top bearing may then be unscrewed for inspection. It consists of a simple brass stud tapped into the register plate and drilled for the reception of the upper end of the shaft.

As already stated, accessibility is a feature of this test meter. The entire meter may be lifted out of the case by removing the screw under the strap in the bottom of the case. All of the connections are made on the rear section of the top plate, so that the register and rotating element may be removed without interfering with the connections or altering the calibration. The shaft is made in three sections as shown in Fig. 15, the top-bearing pivot, the shaft proper and the jewel pivot. The joint between the top-bearing pivot and the main portion of the shaft is made just below the bottom plate of the register.

The Care and Maintenance of Storage Batteries.

If the operator in charge of storage batteries, says F. A. Warfield, will always remember that his batteries will do so much in a given time and no more; that they must be used and treated as carefully as an engine and generator; that any attempt to make them do more than the company which furnished them guaranteed will only involve failure, dissatisfaction and expense, he will have mastered the substance of the best set of instructions for their care. A potential of 2.15 volts per cell is required to start the charge and the author has usually obtained the best results by charging at fifteen per cent above the normal rate, maintaining this rate until the voltage reaches approximately 2.5 per cell. At this point the current should be reduced to the normal rate and the charge continued until the voltage stops rising. When charged in this way the voltage will rise rapidly from 2.15 to 2.25 during the first hour, then slowly until 2.45 volts per cell is reached, then it jumps to nearly the maximum value, at which point it remains practically constant, giving off gas freely at the positive and negative plates, while the solution remains perfectly clear. Under ordinary operating conditions a battery may be considered fully charged when the voltage reaches a constant value, but at least once a week this method of determining the state of charge should not be relied upon. There are three ways of determining when a battery is fully charged: When the voltage reaches a constant value; by the color of the plates, and by the specific gravity of the electrolyte reaching a maximum constant value. It is very important that the battery be fully charged, but it is just as important that it be not overcharged, and to prevent this the specific gravity of the individual cells should be taken at least once a week with a hydrometer as a check upon the voltage readings. Usually a charge twenty per cent in excess of the normal discharge is required. And about once in two weeks an overcharge should be given. This is done by charging normally until the full charge has been given; then the current should be dropped to one-half the normal rate and continued for three or four hours. While doing this the specific gravity will be found to rise for an hour or more after the voltage has become practically constant and the overcharging should be continued until the specific gravity itself becomes constant. If, in case of an emergency, it becomes necessary to charge more quickly than usual, the charge may be started at twice the normal rate and continued until the battery commences to gas and the voltage reaches 2.6 per cell. At this point the electrolyte will have a milky appearance and the battery will be gasing freely. The current should then be reduced to one and a half times the normal rate and the charge continued until the voltage reaches 2.6 again, when the charging current should again be lowered. When a battery is used spasmodically or is kept floating on the line it is a good plan to discharge it at least once every two weeks and then overcharge. The temperature of the cells should never be allowed to go above 100 degrees Fahrenheit, the temperature of the cells near the middle of the battery being watched to prevent this. The best results are obtained when charging with the temperature between seventy and ninety degrees. The electrolyte should be maintained at least one inch over the tops of the plates and the specific gravity should be between 1,200 and 1,225 when fully charged. The following rules should be observed: Never discharge a battery below 1.75 volts; never adjust the specific gravity by adding acid until the cause of the low specific gravity is known; never allow the acid to get below the standard level; always maintain the acid at the standard specific gravity; never let the battery stand in a discharged condition; at frequent and regular intervals give the battery a good overcharge at a low rate; keep the battery and all connections clean; keep all connections tight; remedy all trouble immediately, and use only pure water and pure acid for the electrolyte. —*Electric Journal* (*Pittsburg*), *August.*

The Telephone in Advertising a Play.

During the week a novel use was made of the telephone directory in New York city to advertise the play "Paid in Full." The scheme was to call up every regularly listed telephone subscriber and use a set form of message in apprising the called party of the play and an invitation to be sure to see it. In elaborating the scheme lists of the newly arrived guests at all the leading hotels were secured, and they, too, were reached by telephone.

The Korn System of Image Transmission.

A Detailed Description of the New Apparatus.

By C. L. Durand.

IT will be remembered that Dr. Korn brought his image-transmitting apparatus from Berlin to Paris last year, where it was set up in the offices of the illustrated weekly *L'Illustration* in order to make a public demonstration as to sending the photographs over a wire, and this was quite successful over a long-distance line. Since then the journal decided to take up Dr. Korn's system on a practical scale for newspaper work, and it accordingly had a set of improved apparatus constructed by the Carpentier firm, the successors of Ruhmkorff, who are noted for instrument work on the Continent. One of these instruments is now set up in the building of *L'Illustration* at Paris, where it occupies a special laboratory devoted to this purpose, with a dark room for developing the photographs which are received. The corresponding instrument is in operation at London in the office of the *Daily Mail*. The Paris apparatus is also in connection with one of Dr. Korn's instruments which is set up at Berlin. The transmission between Berlin and Paris is all that can be desired at present and a transmitted photograph of Dr. Glatzel, who is in charge of the Berlin station, is shown herewith. Owing to the compensating selenium method, which is one of the original features of Dr. Korn's method, the details of the photographs are reproduced with great clearness, and the views can be sent within a reasonable length of time. The line between Paris and London includes a telephone cable across the channel, and owing to the inductive effects of the cable the results have not as yet been all that might be expected, but it is hoped to secure a good transmission in the near future.

The station at Paris is in charge of Jules Chatenet, who has kindly furnished the writer with the following points about the new apparatus. Dr. Korn's compensating method, which has not been well understood up to the present, is here described in full, and it is of great interest from a physical standpoint as well as of a considerable practical value. No doubt it will be used in the future by all inventors who are at work upon image-transmission devices. There seems nothing left to be done in the way of transmission of photographs, as Dr. Korn has now solved the problem in a thoroughly practical manner and with remarkable results, but there still remains the attractive and difficult problem of direct vision at a distance, which is far from being solved at the present time.

Each of the complete apparatus contains a transmitter and receiver, and these are mounted side by side upon a suitable support with a motor placed underneath. By changing a lever, the motor mechanism is made to drive either the transmitter or the receiver.

REPRODUCTION OF ELECTRICALLY TRANSMITTED PHOTOGRAPH.

Referring to the outline diagram of the transmitting apparatus, which is shown in Fig. 1, the beam of light is furnished by a lamp which is enclosed in a sliding tube L. For this purpose a Nernst lamp is preferred. By means of a large lens M, placed in front of the lamp, the beam is sent along the chamber to the left, where it reaches a second sliding tube B. This tube contains a lens and at the farther end is a small diaphragm opening which allows a beam of very small size to pass through. The photographic film or positive image which is to be transmitted is wrapped around a glass cylinder A, and this is rotated in a regular way by means of the shaft E. The synchronous motor is made to drive the vertical shaft by means of a suitable mechanism. At the same time the shaft is raised gradually by a screw thread which it carries at the lower part, thus giving a rotating and a vertical movement to the cylinder after the manner of a phonograph cylinder. In this way the beam of light is made to cover all parts of the photographic film. Generally a positive film is used for the transmission, as this will give a negative image at the receiving end. However, a negative film can be employed if desired, in which case the effect is reversed. After passing through the film the beam is received in a total-reflecting prism C, which directs it vertically and allows the light to fall upon the selenium cell D, the light being diffused over the whole surface of the cell. In this way the opaque or transparent parts of the film come into the path of the beam and this action causes more or less of the light to be stopped off. The selenium cell thus receives varying intensities of light which correspond to the different portions of the photographic film.

The receiving apparatus (Fig. 2) is mounted parallel to the transmitter and, like it, consists of a main horizontal chamber with a vertical chamber at one end which receives the rotating cylinder. The mounting of the lamp tube L and the lens M is the same. From this point the beam passes along the chamber and first traverses the galvanometer device W, which is used for cutting off more or less of the beam, according to the amount of current passing in the line. The prism F is not in use when the receiver is being operated, and in this case it is moved to one side and out of the path of the beam so that the light is made to pass through the diaphragm opening E and the adjustable tube D, which contains a lens for concentrating the beam upon the receiving cylinder. The latter cylinder is shown at A, and it is considerably smaller than the transmitting cylinder. Around it is placed a sensitive photographic film which receives the beam, narrowed to a point by a diaphragm. Means must be provided to keep the cylinder A in the dark, after the manner of a roll holder. This is carried out by a tight box B, which contains the cylinder, and the shaft which rotates the cylinder is connected by a coupling piece K to a short piece of shaft which passes through the bottom of the box. As the cylinder has an upward movement like that of the transmitter cylinder, there is provided a long sliding cover CC which is permanently fixed on the end of the tube D and it runs in a groove in the box so as to keep it always covered. There is also a slide which is placed on the box between the cylinder and the tube D (not shown here), so that by closing it the box as a whole can be removed for developing the film.

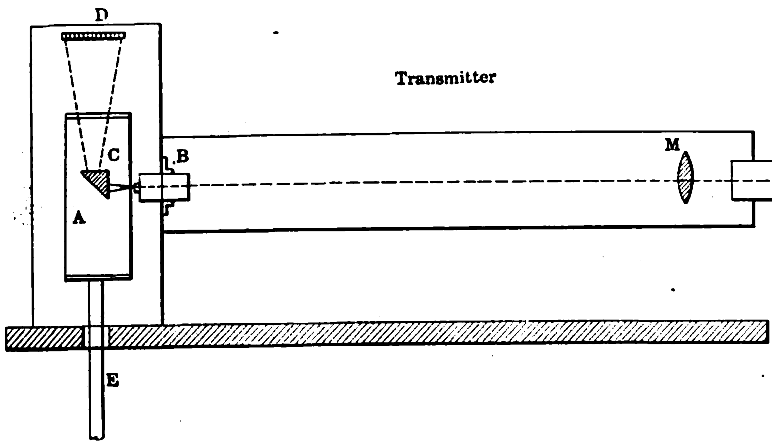

FIG. 1.—THE KORN TRANSMITTER FOR IMAGE REPRODUCTION AT A DISTANCE.

For intercepting a greater or less amount of light, according to the current sent into the receiver, a device which was designed by Dr. Korn is used. It is shown at W, and consists of an electromagnetic shutter which has a small screen moving back and forth in the path of the beam. The movable part T is inserted from the top and lies between the poles of the strong electromagnet N. Openings in the poles allow the beam to pass through. Referring to the detail view of the part T (this can also be seen in one of the photographs), it consists of a supporting rod *a a* upon which is mounted a double stretched wire *b*. For this purpose a fine platinum wire is used. In the middle is mounted a small square of aluminum foil which is exceedingly light. The current coming from the line is made to pass in the platinum wire, and as it is placed in the strong magnetic field the system is displaced to one side and away from the centre as the current passes. The amount of the deflection depends on the strength of the current, but it is not proportional to the latter, as will be mentioned further on. The lack of proportionality is compensated for by a diaphragm placed in the path of the beam at E, which has a triangular opening, so that the amount of light falling on the photographic film is nearly proportional to the current in the line; that is, to the amount of light which has passed through the varying parts of the original image, causing the resistance of the selenium cell to vary in the usual way. Hence, for each part of the original image, light or dark, we have a corresponding resistance of the selenium cell and a corresponding current in the line, giving a greater or less amount of movement to the electromagnetic shutter and hence a corresponding impression on the receiving film.

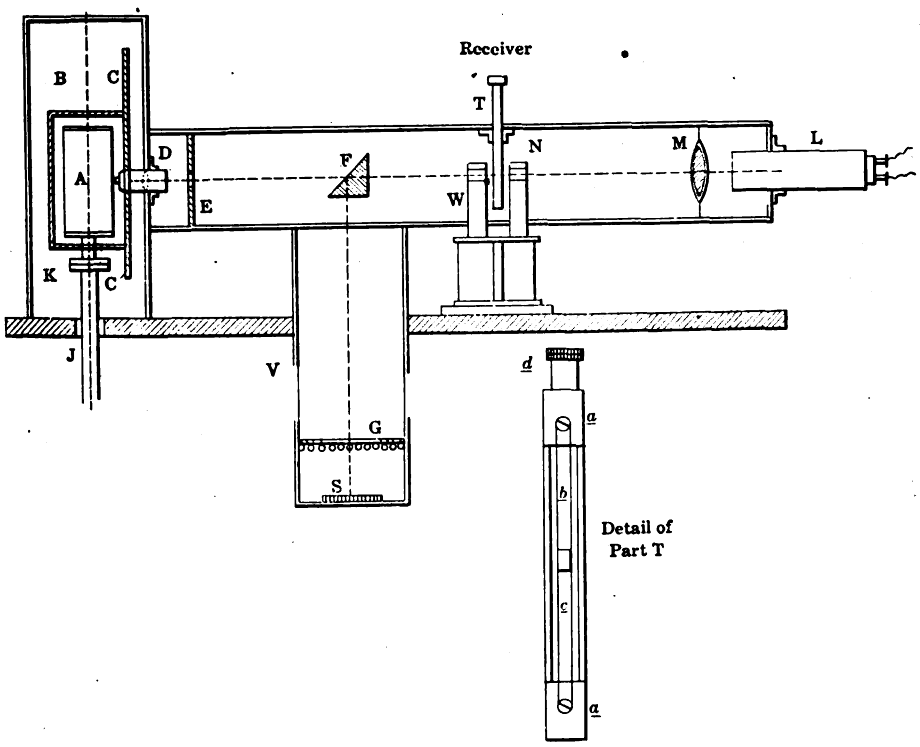

FIG. 2.—RECEIVER OF KORN SYSTEM OF IMAGE TRANSMISSION AT A DISTANCE.

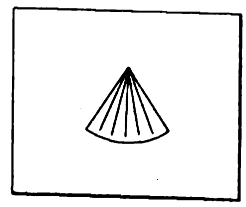
The portion of the apparatus shown at V, including the prism F, does not properly belong to the receiver, but is used in connection with the transmitter when the receiver is not working. This part forms the compensating device which is one of the most ingenious parts of Dr. Korn's apparatus. It is found a great advantage to use a second selenium cell in connection with the main cell in order to overcome one of the main difficulties which is found in the use of selenium, that is, the "inertia" of the cell. As is well known, the cell does not respond at once to the effect of the light which falls upon it, but there is a certain interval of time, or lag, in the change of resistance which takes place. Again, when the light is removed the cell does not come back at once to the original state. This inertia of the selenium has been a serious drawback in the use of selenium cells for the transmission of images, both as concerns the sharpness of the image and the rapidity of transmitting. In order to overcome the effects of the inertia Dr. Korn uses a second selenium cell which is connected electrically with cell No. 1, both cells being placed at the sending station. Cell No. 2 receives light at the same time as No. 1, and the light sent upon both cells depends upon the thickness of the film, but cell No. 2 does not receive the light directly. For this purpose an electromagnetic shutter and a second beam from a lamp are used to throw light on cell No. 2. The



TRIANGULAR DIAPHRAGM PLACED BEFORE THE LENS TUBE (AT E) FOR CORRECTING THE LACK OF PROPORTIONALITY IN THE ELECTRO-MAGNETIC SHUTTER.

shutter receives current from the circuit of cell No. 1. In this way the effect on cell No. 2 is somewhat the same as if it had been lighted directly from the image. The combined current from both cells is now sent into the main line, as will be explained below, and the result is that such current shows but a small amount of lag with reference to the moment of changing the light upon the selenium cells and this practically overcomes the inertia of the cells when in combination, although each of the cells is unchanged and possesses the usual amount of inertia. The method of compensating can only be explained clearly by the use of curves in order to show the resulting effect. The main points as to the compensating method will accordingly be brought out in the theoretical account which follows.

Each of the instruments, transmitter and receiver (Fig. 3 and Fig. 4), is operated by a synchronous motor which will be observed in the engravings. To the motor shaft is connected the mechanism which is used for operating the cylinder in each case. The gearing which drives the cylinder shaft is arranged so that it can be varied by shifting a lever so as to give the normal speed or a slower speed. Usually the normal speed is employed, which gives the transmission of the image in about twelve minutes. Each of the synchronous motors is operated from a local storage battery by direct current. The armature of the motor carries also a ring collector at the other end, and from it can be taken alternating current. Such current is used for operating the frequency indicator. This latter instrument is shown in its essential parts in Fig. 5. A main electromagnet carries the coil W, and the laminated pole-pieces P P′. Attached to the pole-piece P are three tongues of spring steel, A, B, C, which are separated from the second pole-piece by an interval. The tongues are made to vibrate on the passage of alternating current, provided they are tuned so that their normal vibration period corresponds to the frequency of the current. In practice the three tongues are tuned so as to vibrate at 99, 100 and 101 periods, respectively. The upturned ends of the tongues are made to face a dial plate with the corresponding numbers engraved upon it, as will be seen on the right. When the frequency is at ninety-nine cycles, only the first tongue will vibrate. For 100 cycles the second tongue vibrates, etc. For ninety-nine and one-quarter cycles No. 1 vibrates in a smaller amplitude and No. 2 in a still smaller one; at ninety-nine and one-half Nos. 1 and 2 vibrate at a reduced and an equal amplitude. In this way the speed of the motor can be adjusted at each station so as to correspond. As usual in running synchronous motors the motor of station No. 1 (transmitter) is run somewhat slower than motor No. 2. When the cylinder shaft of No. 2 has completed its revolution, it thus arrives at this point somewhat before No. 1, and it is stopped automatically by a pawl. As soon as No. 1 comes to the same point, a current is sent into the line which operates the release of No. 2 by means of an electromagnet. Therefore both shafts start together for the succeeding revolution, and so on. Motor No. 1 is set by the synchronizer at say ninety-nine, while the second operator sets his motor at 101. The stop in the revolution of No. 2 is exceedingly short and does not affect the transmission. At this time a battery current is sent over the line and it is received in a sensitive relay which operates the electromagnet of the releasing device. At the same time the current

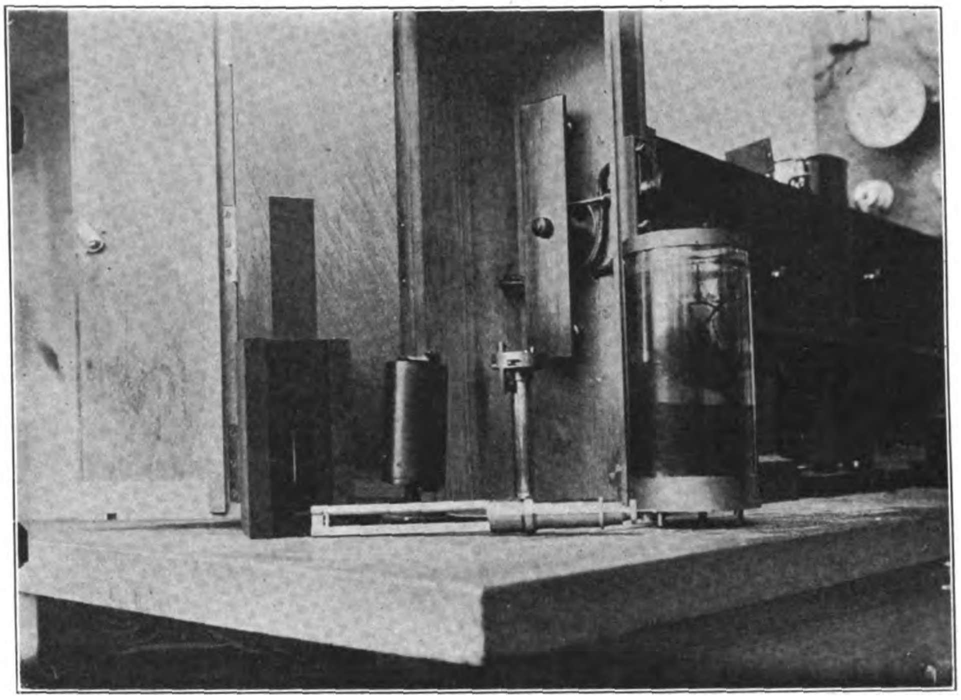


Fig. 3.—One End of the Receiver, Showing Transmitter Cylinder, Motor Shaft, Cylinder, Electromagnetic Shutter and Dark Box.

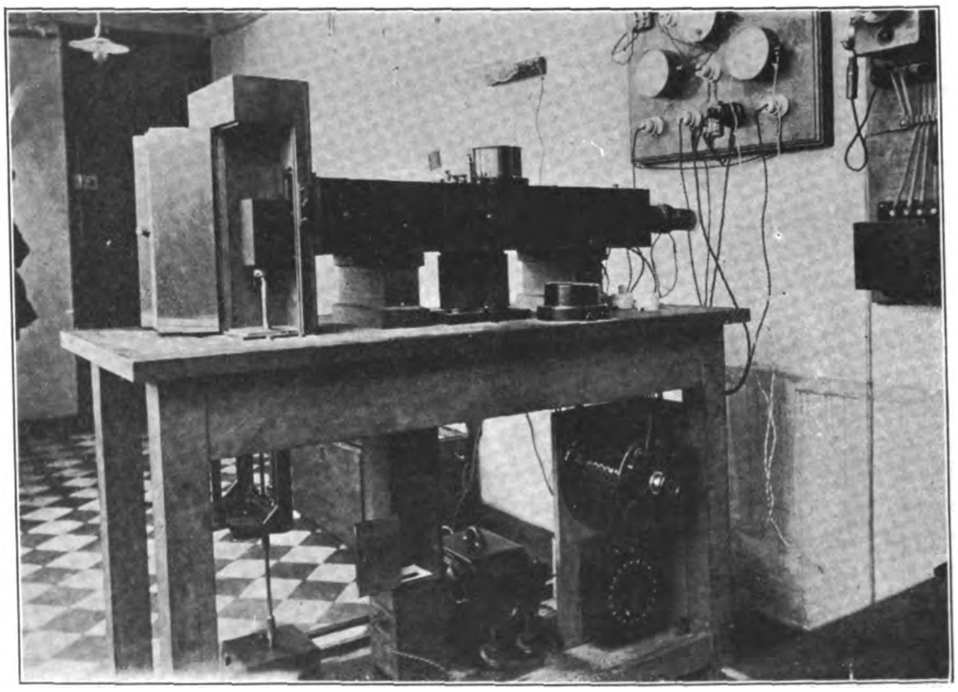

Fig. 4.—Receiver with Dark Box in Place. The Vertical Column is Seen Below, with the Compensating Cell.

from the selenium upon the line is broken automatically for an instant and the receiving electromagnetic shutter is likewise cut out.

The compensating method which was devised by Dr. Korn is of considerable interest, seeing that it is one of the main factors in the success of the present apparatus, owing to the fact that it over-

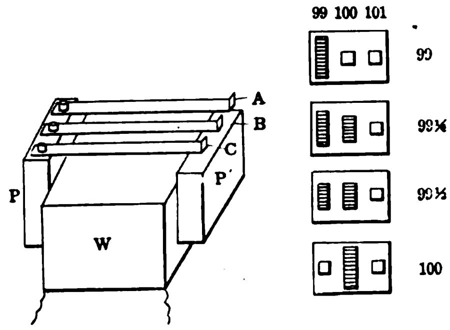

Fig. 5.—Frequency Indicator.

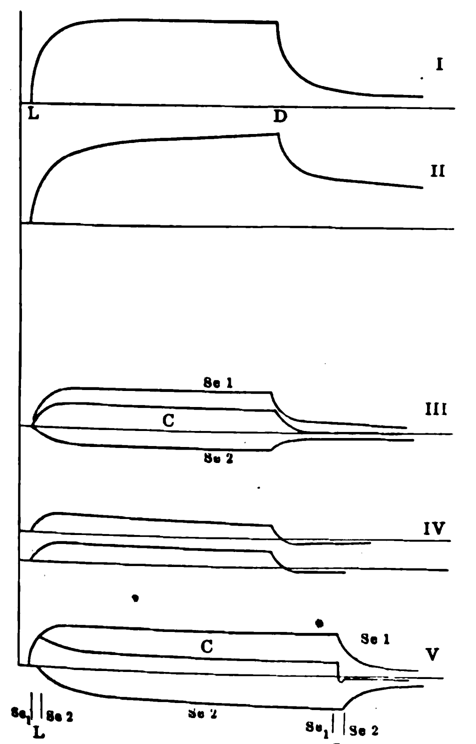
comes the inertia of the selenium cell to a great extent. The result is that the image at the receiving end is much clearer, and at the same time the speed of sending the image can be reduced within a reasonable time, seeing that the



Characteristic Selenium Curves.

impulses of current in the cell can be made in a more rapid succession than could be done were the cell to have the usual amount of inertia.

Curves I and II[1] show the inertia of selenium cells when lighted and then darkened. When lighted (at L) the current rises, but not instantly. When the light is cut off (at D) the current value falls somewhat rapidly at first and then very slowly. In order to secure an abrupt rise and fall of the curve Dr. Korn employs two selenium cells which are of a different character as regards their physical properties and at the same time can be differently lighted if desired. By con-

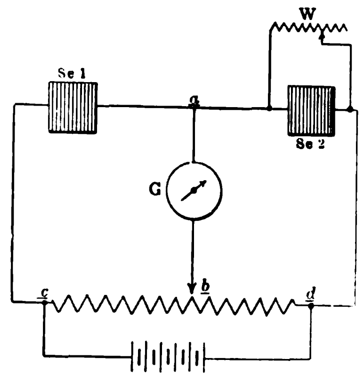


Fig. 6.—Connections of Selenium Compensator.

necting these two cells in opposition in a circuit on the Wheatstone bridge principle he is able to overcome the inertia to a great extent. The connection must be such that the differential current from the combination of the cells is greater than zero when the cells are lighted, and must be zero when in the dark. Referring to Fig. 6, he connects the cells Se^1 and Se^2 in a Wheatstone bridge circuit with the galvanometer G and battery. The bridge is balanced so that in the dark there is no current in the galvanometer circuit *a b*. Taking two cells having a different physical character, it is found that upon lighting them the resistances do not change equally, so that the bridge, balanced in the dark, will be unbalanced when the cells are both lighted at once, and a current will flow in *a b*. Such current will be stronger as the lighting is higher, within certain limits, and it is the difference of the currents which flow in the bridge arms Se^1 and Se^2; it also depends upon the difference of potential in *bc* and *bd* which form the other arms of the bridge. By displacing the contact arm at *b* we can find the best point for the compensation by experiment, and when this is found we proceed to balance the bridge (when the cells are in the dark) by means of the extra resistance W, which is connected across the cell No. 2. As this somewhat alters the first compensation adjustment, we make another adjustment at the other resistance. The result of this combination is shown in curve III, using the oscillograph to take the curves in the different arms of the bridge. In the curves marked Se^1 and Se^2 are shown the usual curves of current rise and fall for each of the two selenium cells taken separately. Here the inertia is large, especially at the drop of the curve. However, the differential current in the galvanometer shown at C is of a different character. The curve rises somewhat more rapidly, but at the drop the fall is much more rapid than usual, and the current value reaches zero very quickly. This effect can be further increased by the use of an over-compensa-

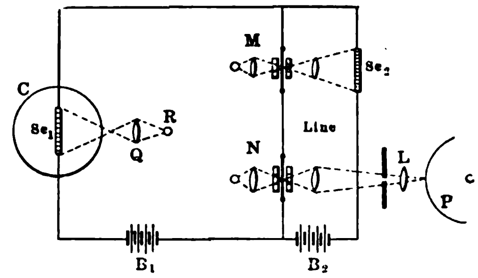

Fig. 7.—Another Means of Securing the Compensating Effect.

tion, so that the curve takes the forms seen in curve IV. Here the current falls below the zero line and consequently the drop is more rapid than before. The current in the galvanometer circuit, which is the one used in practice on the line, should be as large as possible and we should make the best choice of the differences of potential in *ab* and *bc* to carry this out. At the same time the current can be increased by lighting the two cells differently but still at the same moment.

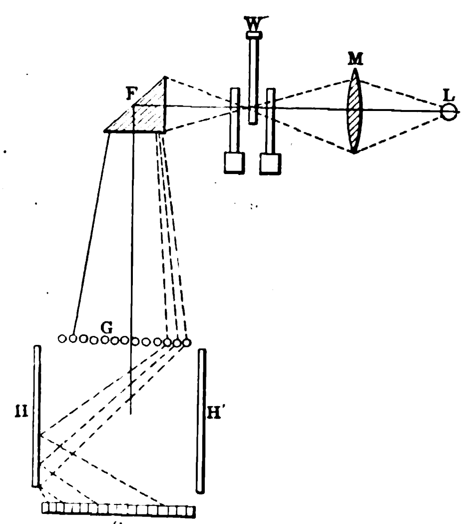

Fig. 8.—Detail of Prism and Diffusing Chamber.

As mentioned above, the two cells must have different physical properties. Dr. Korn employs in general the form of cell which consists of a flat plate of insulating material having wrapped around it a number of turns of double platinum or other wire. Between the wires there is spread a layer of selenium in the usual way. Such a layer may be made thick, and in this case the resistance of the cell

[1] These curves were obtained by Dr. Glatzel of Berlin, to whom the accompanying description is due.

is less. But on the contrary the inertia is greater, as the effect of the light appears to take some time before reaching the under part of the selenium. For a thin layer of selenium the resistance is higher but the inertia is lower. Thus in curves I and II, the former shows the inertia of a 500,000-ohm cell, and the latter the inertia of a 70,000-ohm cell, and it is seen that the low-resistance cell has a much higher inertia. In carrying out the Wheatstone bridge combination just referred to we use a cell Se^1 which has a low inertia and high resistance, while Se^2 is a low-resistance and high-inertia cell.

By the use of the following methods Dr. Korn was able to secure a still better compensating effect. At the transmitting end (see Fig. 7) we have the cell Se^1 which is lighted through the photographic film by the lamp R and lens Q. Cell Se^2 (the compensating cell) is lighted by means of a second lamp and an electromagnetic shutter M, of the type which we have already described. At the receiving end is the electromagnetic shutter N, which causes light to fall upon the photographic film P. The three parts M, N and C are connected on the Wheatstone bridge principle upon the main line. When Se^1 is lighted the bridge balance is destroyed and a current is sent into M. This causes Se^2 to be lighted in turn, but nearly at the same time, the only difference lying in the very slight inertia of the electromagnetic shutter. Se^2 will thus be lighted somewhat later than Se^1. As seen in curve V, curves Se^1 and Se^2 are somewhat displaced and the result is the compensated curve C, which represents the current in the line. This curve has a quicker rise, and it also falls at a faster rate than the former compensated curves. Owing to this fact the instrument is affected by small variations in the lighting, that is in the image, which would be lost in the above method, so that the resulting photograph is finer in the details and therefore much superior.

In practice this is carried out by using the electromagnetic shutter of the receiver which is placed at the transmitting station. When sending the image it is out of action. In this case the reflecting prism F (Fig. 2) is shifted in the path of the beam so as to send it down into the chamber V. Here is placed the compensating cell S. Above it is a screen composed of a set of parallel glass rods G, for diffusing the light over the surface of the cell. This is shown in detail in Fig. 8, where L is the lamp, M the lens, F the prism and W the shutter. At G is a set of glass rods which act as cylindrical lenses. The two plane mirrors H H′ act in connection with the rods to give the diffusion of the light on the cell S.

THE DIRECT PRODUCTION OF COPPER TUBES, SHEETS AND WIRE.[1]

BY SHERARD O. COWPER-COLES.

The numerous processes involved in the production of suitable copper and its subsequent conversion into copper sheets, tubes and wire by a series of operations, such as rolling, drawing and annealing, would occupy too much time to be referred to even briefly; therefore the author has limited the paper to the direct production of copper tubes, sheets and wire by electrolysis from impure copper.

The methods described are all based on the work of Davy and the law of electrolysis established by Faraday in 1833, namely, that when a current of electricity is passed through a solution containing metallic salts and two or more electrodes, one of which is soluble in the solution, a known quantity of metal is transferred from one electrode to the other for a given quantity of electric current; that is to say, if the soluble electrode (the anode) is connected to the positive pole, and assuming the metal and the electrolyte employed to be pure, a weight of metal will be deposited upon the cathode connected to the negative pole, corresponding to the amount dissolved from the anode. If the anode is of impure metal many difficulties are introduced, and if the current is increased to a sufficient density to enable the metal to be deposited at such a rate as will give commercial results, other serious difficulties arise. Electrometallurgists have been working for thirty years or more devising methods to overcome the difficulties experienced in applying Faraday's law to the commercial production of copper tubes, sheets and wire from comparatively impure copper having the physical properties of wrought copper, when deposited at a sufficiently rapid rate.

The refining of copper by electrolysis has now assumed vast proportions, and the annual output of electrolytic copper in the year 1907 has been estimated at 400,000 tons, equal to fifty-six per cent of the world's production, and the capital sunk in the industry at about $75,000,000. The whole of the copper thus produced is in the form of rough slabs or cathode plates which have to be smelted and worked to the desired forms.

Electrometallurgists have been striving for many years to devise a process which does away with the smelting of copper after it has been electrolytically refined, and to electrodeposit copper after the refining operation in such a form that it can be placed direct on the market as finished sheets, tubes and wire.

[1] Abstract of a paper read at the Bristol meeting of the Institution of Mechanical Engineers, July.

WILDE'S PROCESS.

It was observed shortly after Elkington practically applied Faraday's law to the refining of copper in the year 1865, that the electric current density, or the rate at which the copper is deposited, could be considerably increased by circulating the electrolyte or moving the electrodes. It was soon found that circulating the electrolyte alone was unsatisfactory, and that the best results could be obtained with a vertical mandrel revolved in the electrolyte. Wilde was one of the first to use a cylindrical cathode, his object being to deposit copper on iron rollers suitable for textile printing purposes, for which he took out a patent in the year 1875. The anodes consisted of copper cylindrical tubes, and the iron cylinder to be coated with copper (the cathode) was placed in the centre of the cylindrical vat and caused to rotate on its axis. Such an arrangement, in conjunction with a circulating propeller placed in the electrolyte, insured an even distribution of copper over the whole surface uniformly along the length of the roller by means of the motion imparted to the solution, and the equal density thus maintained. The current density was low, considerably under twenty amperes per square foot.

ELMORE'S PROCESS.

The next development of importance was the Elmore process, which consists of using horizontal mandrels on which copper sheets or tubes are deposited, while agate burnishers travel continuously over the copper, so as to consolidate it, and at the same time prevent the growth of copper trees or nodules. Even with the use of a burnisher the current density could not be increased beyond thirty amperes per square foot, and the mechanical difficulties introduced by the burnisher are considerable. Large works were erected to operate this process near Leeds and on the Continent, and are principally engaged in the production of large tubes and cylinders for special purposes.

DUMOULIN'S PROCESS.

Dumoulin introduced, at a later date, a process for burnishing copper during deposition with sheepskin as a substitute for agate, and claimed that the process had also the advantage of insulating any projections that might be formed on the deposited metal, the sheepskin impregnator coating all projecting parts with a film of animal fat, thus preventing further deposition until the surrounding depressions are raised to the common level. It was also claimed for this process that a current density of from thirty to forty amperes per square foot of cathode surface could be employed at a voltage of about 1.6 per vat. This process was tried on a large scale in England but was soon abandoned.

OTHER PROCESSES.

Attempts have been made at various times to further increase the rate of deposit by Swan, Elmore, Thofehrn, Graham, Poore and others, by impinging jets of the electrolyte against the cathode surface. The quality of the copper is liable to vary in density if impinging jets alone are employed; it is therefore necessary to move the cathode, otherwise the copper is deposited in the form of annular rings of varying density and smoothness.

The author, when carrying out some experiments on the production of copper tubes and sheets by electrodeposition on rotating cathodes, observed that when the speed was greatly increased entirely new results were obtained, and that a current density of 200 amperes or more per square foot could be employed, the copper remaining smooth and having a tensile strength equal to the best rolled or drawn copper, and in some cases a tensile strength some fifty per cent higher than that obtained by the ordinary process of casting and rolling, the tensile strength increasing with the rate of rotation of the mandrel. The result of revolving a mandrel at a comparatively high speed is that every molecule, as it is deposited, is burnished or rubbed down so as to produce a tough fibrous copper, the usual order of things being reversed, the present practice being to put the mechanical work into a mass of copper by rolling or drawing instead of treating each molecule separately.

CENTRIFUGAL PROCESS.

This observation led to further experiments, which resulted in evolving the process now known as the centrifugal copper process for the manufacture of sheets, tubes and wire, which will now be described in detail, together with the results obtained.

After a long series of experiments had been made to determine the best composition for the electrolyte and the most economical current density to employ, the critical speed was accurately determined by means of revolving cathodes in the form of cones. By observing the point at which the copper remains smooth, and by measuring the circumference of the cone at that point and multiplying it by the number of rotations per minute, the critical speed is readily determined; 200 amperes per square foot is found to be the most economical current density, although a current density up to 500 amperes per square foot can be employed by increasing the rate of rotation, but the increased cost due to increased voltage renders such a current impracticable for ordinary commercial work.

One of the chief difficulties inherent in any electrolytic or wet process for the production of copper tubes and sheets is having any working parts, such as bearings, in an acid copper sulphate solution, and this was one of the first troubles encountered when working the centrifugal process on a commercial scale. This difficulty was eventually overcome by constructing vats in the form of an annular ring, as shown in Fig. 1. It will be observed that by such an arrangement all

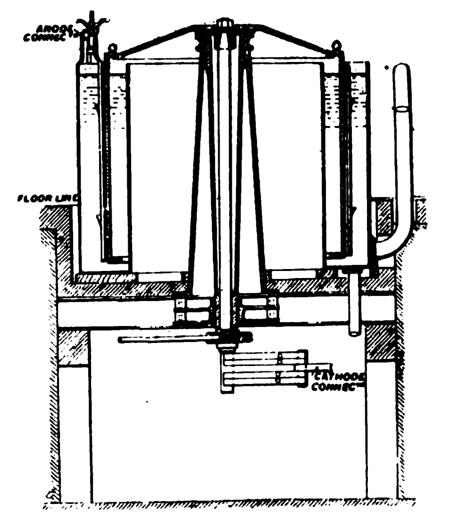

FIG. 1.—VAT USED FOR CENTRIFUGAL PROCESS.

working parts are outside the vat and do not come into contact with the electrolyte, so that the bearings can be lubricated in the ordinary way; only the actual face of the mandrel on which the copper is to be deposited is immersed in the electrolyte. The cathode consists of a steel or cast-iron cylinder closed at one end, to which is attached, on the inside, a steel rod projecting below the edge of the mandrel to guide it into position; the cylinder can be five or six feet in diameter or even larger so as to produce a copper sheet of say twenty feet long by four or five feet broad. Anodes composed of crude copper are placed around the mandrel with intervening spaces and are fed forward by suitable mechanical means as the copper dissolves away so as to keep the voltage constant.

One great advantage of the centrifugal process is that a very low voltage is required even when employing a very high current density; for instance, only 0.8 of a volt is required at the terminals of the vat when working at a current density of 200 amperes per square foot of cathode surface. The effect of revolving the cathode is fivefold: Firstly, it keeps the electrolyte agitated, so that there is always a fresh supply of copper ions in proximity to the cathode; secondly, each molecule of copper as it is deposited on the cathode is burnished or rubbed down by means of the skin friction between the revolving cathode and the electrolyte; thirdly, the rotation prevents any foreign matter that may be in suspension in the electrolyte settling on the cathode and becoming entangled by further copper being deposited around or over it; fourthly, it brushes away any air-bubbles on the cathode, which are the cause of nodules forming; and fifthly, the rotation of the cathode insures the thickness of copper being uniform even when a mandrel of say eight feet in length is employed.

The method of making tubes by the centrifugal process is as follows: A mandrel somewhat smaller than the finished internal diameter of the tube is prepared by coating it with an adhesive coating of copper by first depositing copper upon the surface from an alkaline solution and then thickening it up in an acid solution, the surface being highly burnished and treated chemically to insure the easy removal of the deposited tube. The mandrel thus prepared is then placed in a vat as shown in Fig. 1, according to the diameter of the tube and its length. When the desired thickness has been obtained the mandrel is removed and placed in a horizontal or vertical lathe, and a round-faced roller run over the surface so as slightly to expand the deposited copper, which can then be readily drawn off.

Copper sheets are prepared in a similar manner, the only difference being that the mandrels are of much larger diameter, and a narrow insulating strip is fitted down one side so that the sheet can be easily removed by inserting a tool under one of the edges of the deposited copper. It is no more costly by the centrifugal process to make thin sheets than thick ones; copper foil can be made like the samples exhibited in five minutes direct from crude copper.

Copper tubes produced by this process without any drawing have given a maximum stress of seventeen tons, and tubes after drawing have withstood a pressure of 3,000 pounds per square inch without showing any signs of distress.

Sheets made without any rolling have given a maximum stress of twenty-eight to thirty tons and more per square inch according to the peripheral speed at which the mandrels were revolved.

The formation of copper trees and nodules was another difficulty that had to be overcome, but which has been reduced to a minimum in the centrifugal process, for the reason that impurities held in suspension in the electrolyte have no opportunity of settling on the cathode, and all gas bubbles are swept from the surface on which the copper is being deposited.

The percentage of free acid employed in the centrifugal process is high, amounting to twelve or thirteen per cent. The electrolyte, the usual composition of which is 12.5 per cent of copper sulphate and thirteen per cent of sulphuric acid at a temperature of forty degrees centigrade, is kept in the cupric state and the impurities in suspension separated by means of a centrifugal filter provided with arc lights and an atomizer for breaking the solution up into a fine spray, as shown in Fig. 2 and Fig. 3, respectively. It has been found that by subjecting the solution to a strong light the impurities are more easily precipitated, and the solution is kept in the cupric state.

The production of copper wire by electrolytic means is a more difficult problem than the production of copper tubes and sheets. Various processes have been suggested and tried from time to time, such as the electrodeposition of copper on thin wire, until it has obtained a considerable thickness, and then drawing the thickened wire down to a comparatively fine wire. Swan and Saunders have both experimented with such processes, but so far they have not been worked commercially.

Elmore's process consists of producing copper tubes by his burnishing process, cutting them into long spirals and then drawing them into wire.

Other experimenters have tried placing an insulated spiral strip on a cylindrical mandrel so as to produce long copper spirals, but such an arrangement only allows of a very low current density being employed, on account of the nodules which form on the edges of the strip, even at very low current densities, rendering the strip unsuitable for drawing down into wire.

Copper wire is made by the centrifugal process in the following manner: A mandrel similar to that used for making copper sheets is employed, around which a spiral scratch is made, the pitch being determined by the size of wire required.

The effect of the spiral scratch (which need only be very light but must be angular) is to cause the crystalline structure of the copper to form a cleavage plane, as shown in Fig. 4. It will be observed that the copper divides exactly at the apex of the scratch, that is, the copper deposited in the scratch is equally divided and forms a small V-shaped fin on two sides of the copper strip. If the scratch is not angular, but rounded at the base, the copper will not divide, as the crystals are radial. After the desired thickness has been obtained, approximating the pitch of the spiral scratch, the mandrel is removed from the depositing cell and placed in a vertical position on a lathe and the copper strip is unwound at an angle of about forty-five degrees to the face of the mandrel. During the process of unwinding the small fin or burr is removed by passing the wire through a suitable die and then through a wire-drawing machine provided with three or more draw-plates to reduce the strip to the desired diameter. By employing a mandrel of six or seven feet in diameter, lengths of wire four or five miles long can be made in one operation.

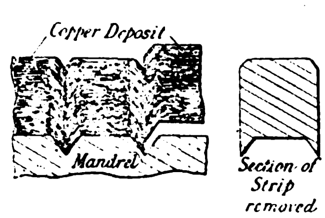

FIG. 4.—DIAGRAM SHOWING METHOD OF FORMING WEAK LINE OF CLEAVAGE DUE TO CRYSTALLINE STRUCTURE.

CONCLUSION.

The advantages of an electrolytic process as compared to a smelting process are many and the day is not far distant when copper will no doubt be leached direct from the ore and electrolyzed with insoluble anodes, to produce finished copper sheets and tubes in one operation direct from the ore without the intermediate process of smelting and refining.

The centrifugal process is a step in this direction, as it is capable of depositing copper from its solutions by using insoluble anodes in the form of finished tubes or sheets in one operation. The centrifugal process is at least ten times faster than any existing electrolytic process, and a high current density can be employed without deteriorating the quality of the copper. There is no risk of lamination, as no burnishers are employed. The plant is simple and free from mechanical complications, and the amount of copper locked up for a given output is small compared to other processes.

APPENDIX.

The following is a typical analysis of the copper produced by the centrifugal process:

Iron	0.0189
Arsenic	0.0015
Lead	0.0013
Antimony	0.0010
Bismuth	0.0008
Silver	absent
Nickel	absent
Sulphur	absent
Copper (by difference)	99.9765
	100.0000

Under favorable conditions the theoretical weight of copper is obtained, and the table (I) gives the weights and thicknesses of copper deposited in an hour at the current densities usually employed.

The capital expenditure of a plant for the centrifugal process both for the manufacture of sheets, tubes and wires, compares very favorably with an up-to-date rolling mill and wire-drawing plant. The cost of such a plant, with buildings, is about $400,000 for an output of 100 tons per week or 5,000 tons per year. The following is an estimate of the cost of a plant for the centrifugal process capable of dealing with 10,000 tons of tubes, sheets and wire per annum:

ESTIMATED COST OF PLANT FOR PRODUCING 10,000 TONS OF TUBES, SHEETS AND WIRE PER ANNUM BY THE CENTRIFUGAL PROCESS.

Cost of ninety-five vats and accessories	$320,000
Machinery for finishing tubes, sheets and wire	25,000
Cranes and lifting gear	7,500
Building	75,000
Plant for mandrel-making	10,000
Machinery for fitting shop	7,500
Pumps, atomizers, filter tanks	25,000
Driving machinery for vats	25,000
Conductors and electrolyte	25,000
	$520,000
Floating capital for copper	150,000
	$670,000

TABLE I.

TABLE GIVING THE WEIGHT AND THICKNESS OF COPPER DEPOSITED PER HOUR AT VARIOUS DENSITIES WITH METRICAL EQUIVALENTS.

Current Density in Amperes per Square Foot.	Weight of Copper Deposited per Hour per Square Foot. Pound.	Thickness of Copper per Hour. Inch.
150	0.3893	0.00872
160	0.4153	0.00930
170	0.4413	0.00988
180	0.4672	0.01046
190	0.4932	0.01105
200	0.5191	0.01163
210	0.5451	0.01221
220	0.5710	0.01279
230	0.5970	0.01337
240	0.6230	0.01395
250	0.6489	0.01453

ESTIMATE OF COST PER TON OF PRODUCING COPPER TUBES, SHEETS AND WIRE BY THE CENTRIFUGAL PROCESS DIRECT FROM CRUDE COPPER.

Power per ton (2,240 pounds), 1,015 kilowatt-hours at 0.55 cents per kilowatt-hour	$5.58
Wages at 16 cents per hour, 18½ hours	2.96
Management	1.25
Interest on copper lock-up	.25
Depreciation on plant and building	2.50
Heating electrolyte	.25
Finishing and gauging	1.25
Cost per ton	$14.04

These figures represent the actual working cost on which there would be a further reduction of the precious metals recovered and if $7.50 be deducted from the above cost, which may be taken as an average difference between Chili-bar and electrolytic copper, the cost per ton is reduced to $6.62.

Chicago Street Railway Accidents.

The Chicago City Railway Company announces that the number of fatal accidents for the first half of 1908 was the lowest on record, there being only one killed in every 4,172,727 passengers carried. This is stated to be a direct result of the use of the new pay-as-you-enter cars.

Electric Smelting by the Lash Process.

In the summary report of the mines branch of the Canadian Department of Mines for the 1907-1908, recently published, some attention, says the *Iron Trade Review*, is given to the solution of the problem of the direct production of steel from the ore, in connection with which technical difficulties have been encountered. It is thought that these may be overcome by the application of the Lash steel process in an electric furnace, and the Canadian Lash Steel Process Company, of Niagara Falls, furnishes a description of its working. Successful experiments with this process in the case of the open-hearth furnace on a commercial scale indicate its possibilities with regard to electric smelting. In this process finely divided ore is mixed with carbon, a certain quantity of finely divided carboniferous iron, such as cast-iron borings, or granulated pig iron, sawdust and fluxes suitable for the iron ore under treatment. The working of the process can best be explained by comparison with the open-hearth "ore process," which consists in forming a bath of molten pig iron and then adding thereto a sufficient amount of ore (iron oxide) to reduce the carbon content of the metal to the desired amount. The oxygen of the ore, combining with a certain amount of the carbon in the pig iron, forms carbon monoxide gas and sets free the iron of the ore to mix with the bath of molten metal. Thus a mixture of approximately seventy-five per cent pig iron and twenty-five per cent ore can be worked up. But in the Lash process the proportions are very different, for a large proportion of ore can be used with a small percentage of carboniferous iron. A typical mixture has the following percentage composition:

	Per Cent.
Iron ore	54
Cast-iron borings or granulated pig iron	27
Sawdust	4
Limestone	4
Coal tar	3
Coke	8
	100

These constituents are finely divided and intimately mixed, and when heated to a high temperature the reactions that occur are similar to those found in the open-hearth furnace using the ore process. The cast-iron borings correspond to the molten bath of pig iron and react with the ore, but the latter being in large excess it is necessary to supply a certain amount of free carbon in the form of coke for the complete reduction of the ore. The great economy of the process lies in the substitution of a large amount of ore for pig or scrap iron. In using the Lash mixture in the open-hearth furnace it is necessary to have a bath of molten metal, as otherwise it would not be practicable to heat it to the reacting temperature without losing carbon in the mixture by combustion. If, however, the charge is put into an electric furnace, no difficulty of the kind is experienced, since the gas in an electric furnace is neutral, in contradistinction to the oxidizing atmosphere of an open-hearth furnace. Experiments using the Lash mixture have been made in the electric furnace on a small scale with successful results. It was found that the yield of metal amounted to ninety-eight per cent of the metallic content of the mixture. The average cost of the materials in Canada for the production of 100 tons of steel ingots in the regular open-hearth furnace is $20.79 per ton, and it is claimed that by using the Lash mixture in the electric furnace this can be reduced to $16.22 per ton, and that the technical difficulties which have been encountered in the production of steel directly from the ore by electricity will disappear. Different electric furnaces are being tested to ascertain the type most suitable for the application of the process.

Functional Organization for the Central District and Printing Telegraph Company of Pittsburg.

A new form of organization, similar to that being put into effect by the New England Telephone and Telegraph Company and other large Bell subsidiaries, has been adopted by the Central District and Printing Telegraph Company, of Pittsburg, Pa. The organization was effective September 1 in Allegheny County and will be extended to the balance of the company's territory at as early a date as practicable. M. C. Rorty has been made general superintendent, S. P. Grace general superintendent of plant, and F. O. Hale general superintendent of traffic.

The Pennsylvania Electric Association.

The first convention of the Pennsylvania Electric Association will be held at Eagles Mere, Sullivan County, Pa., September 8 and 9. Arrangements for the accommodation of those attending the convention have been made at the Forest Inn Hotel, Eagles Mere Park. The secretary of the association is E. L. Smith, of Towanda, Pa.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

The Rose Recording Target.

A form of recording target which requires only three wires and yet reproduces the record of the shot at the point of fire, showing the point where the bullet hit within one-sixteenth of an inch, is described here. It is the invention of S. A. M. Rose, of Melbourne, Australia. By this instrument much time and possible misunderstanding and considerable expense may be avoided. In its simplest form the target is intended for showing the results of single shots, but it can be adapted to volley firing by the addition of a cable which takes the place of the three wires. The advantages of this target are its simplicity, as compared with other automatic recording targets; the fact that no more or less delicate mechanisms are subjected to the violent impacts of the bullets, and the actual targets can be preserved for record if desired or may be patched up for immediate use again. The target is printed on a roll of paper or cloth at regular intervals, and means are provided for exposing a new target by winding off the roll on to a drum. This traversing of the paper is effected by some means which gives absolute synchronism at the firing point with a smaller roll of paper, upon which the record is reproduced. As the target is rolled off it passes under a row of contact fingers, each finger of the set being connected to a point of a resistance in an electric circuit running to the recording station. When a hole in the target passes under these fingers certain ones fall through and make contact on a bar underneath. The position of the fingers determines the strength of the current which flows, and this current at the receiving recording station draws up the core of an electromagnet to a corresponding height, thus bringing a pencil or other marking device to the position on the record corresponding to the hole made by the bullet. Two guide marks are punched on the target and are marked on the record in their proper positions and enable a transparent gauge to be placed upon the record and show the exact locations of the shot. This target could be used for volley firing and would show correctly any number of shots at once if not more than one shot fell in line with the contact fingers at once. In that case the recording pencil could not record properly. To reproduce properly such a record it is necessary to run a wire from each contact finger to the recording device, where there is a magnet and stylus for each finger. When these styluses are drawn against a ribbed back they tear slits in the record showing exactly the location of holes in the original target. These tears can not be obliterated or imitated. With a target six feet square and contact fingers a sixteenth of an inch apart, 1,152 wires are required for Rose's apparatus, but since this cable is used intermittently only it could be used for a large number of targets. Other recording systems to give an equivalent record would require the square of this number of wires.—*Abstracted from the Electrical Engineer (London), July 31.*

The Tantalum Wave Detector.

A description is given here of a new electric-wave detector, devised by L. H. Walter, the idea being to make use of the indifference of tantalum to the atmosphere and to mercury and the spontaneous decohering property of mercury. This combination has been made practical by the introduction of the tantalum lamp, since before this tantalum was not procurable. The first experimental detector was made by passing two tantalum wires taken from an ordinary tantalum lamp through two capillary tubes of glass, allowing the wires to project about one-twentieth of an inch and their points just to touch the surface of a small pool of mercury. Trials of this detector gave good results and it was found that both the liquid dielectric and the insulating sheathing could be dispensed with. The actual device consists of a glass stem through which two platinum wires are sealed, similar to the arrangement used in incandescent lamps. One of these wires is longer than the other and is allowed to project down into the mercury. The shorter one is formed into a clip into which a short piece of tantalum wire is inserted. The whole is enclosed in a small glass bulb into which enough mercury is poured to make contact with both wires. The bulb is then sealed up. It may be exhausted if thought desirable. With this arrangement connections are easily made by means of the platinum leading-in wires. The tantalum wire is about 0.05 millimetre in diameter and should have its lower end just immersed in the mercury. When thus constructed the device appears to be permanent and not to deteriorate and is not too fragile to transport. Detectors of this form have been tried in actual wireless work. They do not seem so sensitive as the electrolytic or magnetic detectors for very weak signals, but for slightly stronger signals they give sounds several times as strong as the electrolytic, which is itself more sensitive than the magnetic. With the second detector made, signals were obtained from a distance of seventy miles over sea without any attempt at tuning. These sounds were louder than those given by an electrolytic detector with the aid of a step-up oscillation transformer and careful tuning. One of the less satisfactory of a later model of this detector has given satisfactory signals at a distance of 450 miles from an ordinary ship installation of two kilowatts. By means of the resistance substitution method it has been found that in the receptive condition the resistance is only 1,200 or 1,800 ohms (the electrolytic is 30,000 or more), and this low resistance should be beneficial for tuning. When oscillations are acting the resistance drops to anything from 250 ohms for strong signals to perhaps seventy ohms for very strong signals. The ratio of the current when oscillations are acting to that in the normal condition is from 3 to 1 to 8 to 1, and may be as much as 30 to 1. On account of this characteristic the inventor thinks the tantalum detector is particularly adapted to wireless telephony since here the use of microscopically weak signals is out of the question, and it is here that the superiority of this detector for moderately strong signals will be useful. The form of detector described above, while suitable for fixed stations, does not work well when it is subjected to shaking or mechanical shocks, as experienced on shipboard. To meet this requirement a form in which the mercury is rendered immobile has been developed. The platinum wire with the clip is sealed into a minute glass bulb, to which a capillary tube is attached. The tantalum wire passes through this tube. The whole is exhausted and sealed. Then the tube is carefully heated until it collapses on the tantalum wire. The tube is then ground off so as to present the end of the tantalum wire. This tube is slipped through an ivory plug, which is in turn inserted in a second glass tube about five-sixteenths of an inch in diameter. A little mercury is poured into this tube, so as to be in contact with the exposed end of the tantalum wire, and the tube is closed with a second ivory plug through which a platinum wire passes. The outer tube is then placed in an ebonite tube for protection and is mounted so as to be rotatable about a horizontal axis. The most sensitive position is with the tantalum wire at the top. The outer glass tube should be about five-thirty-seconds of an inch in diameter. A larger tube would be more sensitive and constant but not free from the effects of vibration. A smaller tube gives a less sensitive and more variable detector. Although tantalum, the first metal tried, gave such good results, a number of others were experimented with, such as iron, nickel, tungsten and certain alloys, but all of these gave perfect contacts and were therefore not suitable. No effect was obtained with vanadium, molybdenum, cobalt, manganese, tellurium, zirconium, ferro-silicon, ferro-manganese, ferro-nickel, antimony or bismuth. But a fairly sensitive and moderately loud detector can be made, using pure tantalum on several solid metals. Oxidized iron seems to be the best, but an equally sensitive, though not so loud, instrument is given with tantalum on tellurium. None of these arrangements at all compares with the tantalum-mercury instrument. — *Abstracted from Electrical Engineering (London), July 3.*

On Earth Currents and Magnetic Variation.

The relation between earth currents and magnetic variations is very far from being known thoroughly. The main question, according to Dr. L. Steiner in this article, is whether the magnetic variations are entirely, or at least partly, due to the electromagnetic action of earth currents, or whether they are in turn induced by the magnetic variations. It has not yet been satisfactorily answered. Many investigators are inclined to accept the former view, relying mainly upon observations made at times of magnetic storms. The few data at our disposal concerning the daily variations on calm days have not yet settled the question. The elaborate investigations dealing with this subject—the well-known investigations of Professor Weinstein—advanced the problem considerably, but they do not lead to final results. If the earth currents are the primary causes of the daily magnetic variations, then we should expect that the west-east components of the currents are connected with the north components of the magnetic variations, and the north-south components of the currents with the west-east components of the magnetic variation. The observations at Paris seem to confirm such a connection for the west-east currents, but the connection for the north-south currents is not so evident. Schuster, von Bezold, and Fritsche have shown that the daily variation of terrestrial magnetism is to be ascribed to two causes, one outside, the other inside the earth. The numerical separation of the two, as far as the data permitted, has been done by Fritsche. A tabulation of his results, which is given, shows an obvious parallelism between the east-west earth current and the north-south magnetic variation, but no connection between the north-south current and the east-west magnetic variation. Deriving, however, the differential coefficients for the latter variation, a direct variation apparently results. If we imagine the earth current contained between two plates in the earth is closed somehow in the interior of the earth, then an increase of the magnetic force to the west induces—in conformity with Maxwell's rule—an earth current in the north-south direction, and a decrease of the force to the west, an earth current in the opposite direction. The table of coefficients shows these characteristics. The extreme values and the changes of sign occur in the differential coefficients at the same time, or a little earlier, than for the earth currents, which seems favorable to the supposition that these currents are induced by the changes in the earth's magnetism. The agreement is not so close for winter as for summer, which is not surprising when all the complex factors entering into the phenomena are considered. By tabulating Fritsche's and Weinstein's results for the Berlin-Dresden line and the Berlin-Thorn line a loose agreement between the earth currents and the north-south magnetic variation only is found for the latter line, while the former shows a remarkable agreement between the earth currents and the differential coefficients of magnetic variation. This seems to prove that a part at least of the daily magnetic variations is related to the earth currents in such a way that the north-south magnetic variations are partly electromagntic actions of the east-west currents and the north-south earth currents are partly induced currents caused by the variations of the east-west magnetic variation. If these remarkable connections be real then the relation of the earth currents and the magnetic variations is more complicated than would at first be supposed, and the physical explanation of it seems to present great difficulties. Why should the east and west currents act as primary causes and the north-south currents behave like currents induced by the east-west magnetic variation? The sun may have something to do with this, as the temperature gradient caused by its daily action is greatest in the east-west direction, and may thus give rise to earth currents in the same direction. These currents may be looked upon as primary currents. The unsymmetrical distribution of the stream lines in the east-west direction allows us to expect a magnetic force in the same direction, and the variation of this component will induce currents in the north-south direction. This explanation, however, is easily attacked, and the above apparent connections still await explanation. Schmidt has put forward the hypothesis that the earth currents are due to induction in the wires. Weinstein holds the contrary view. It seems possible that, so far as the inner agencies of magnetic force are considered, there may be a difference between the north-south and the east-west currents with regard to their origin.—*Abstracted from Terrestrial Magnetism and Atmospheric Electricity (Baltimore), June.*

A New Smokeless Fuel.

A patent fuel has recently been brought out by a French inventor, designated as "charbonnette." This fuel, it is stated, can be produced for about two-thirds the cost of coal. It lights easily and, rapidly becoming incandescent, no smoke is emitted, while at the same time it gives out intense heat and leaves very little ash. It is manufactured in briquettes, and its main features are cleanliness in handling and the absence of odor. It is understood that the preliminary tests have been so satisfactory that a manufactory is to be erected.

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

SUCTION GAS PRODUCER POWER.

AMERICAN PRODUCERS FOR AMERICAN COALS AND LIGNITES.

BY L. P. TOLMAN.

The early history of producer gas dates as far back as the year 1509, at about which time the "Fulen Heitzen" first became known, and were described by H. Brunschwyk in his book "Ars Distillandi de Compositis," or "The Art of Distilling Compounds," which was published in Strassburg, Germany.

The first plant similar to those now in use was built by Emerson Dowson, who has the distinction of introducing, in England, in 1878, the first practical gas producer for power. This was of the "pressure" type. A small steam boiler was necessary, as well as a large gas holder.

Then followed the invention of Herr C. Wiegand, of Hanover, Germany, who in 1895 took out the first patent (No. 88,044, German) on the principle of the modern suction gas producer. The importance of this invention was not realized in Germany until some years later.

In France, during the same year, Benier built what is believed to be the first practical suction gas producer. This was a success as soon as the necessary changes had been made in the gas engine to adapt it to the "suction" system. It is surprising in this case, as with most other great inventions now in general use, that an apparatus so simple and easily understood was not developed long before.

About five years ago American manufacturers began to take a live interest in the success of European, and especially German, suction gas power plants. factory installations already in operation on American coals. It is estimated that there are over 500 producer power plants in this country, having an aggregate of 150,000 horse-power. Of these, about eighty-five per cent are of the "suction" type and fifteen per cent of the "pressure" type. The suction plants average approximately 100 horse-power each while pressure plants are usually built in sizes larger than 1,000 horse-power.

This article deals with suction gas power plants in single units of 200 horse-power, or smaller, and complete plants made up of a number of such units, 1,000 horse-power or larger. This range of sizes covers the requirements of the great majority of power users.

Fig. 1 illustrates a suction gas producer power plant. The apparatus is simple, reliable and economical. With

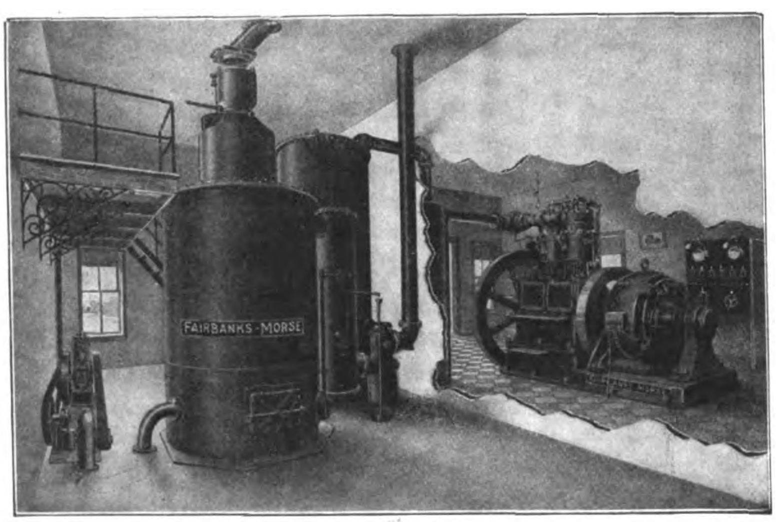

FIG. 1.—COMPLETE PRODUCER-GAS POWER PLANT, WITH ENGINE DIRECT-CONNECTED TO DYNAMO.

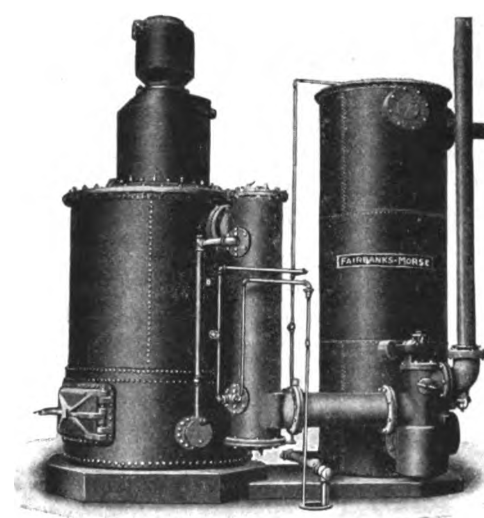

FIG. 2.—FAIRBANKS-MORSE SUCTION GAS PRODUCER.

Mr. Dowson's plants were successful and are still in regular service. Anthracite is the usual fuel.

The next substantial progressive step was taken when Dr. Ludwig Mond, in England, in 1889, developed the first successful soft-coal producer. This became a standard for sizes of 250 horse-power and larger but proved too elaborate and expensive for use in smaller sizes. With this plant a large gas holder is needed, also a steam boiler and an elaborate system of gas washers, purifiers and economizers.

American engineers visited Europe and in this way learned at first hand what was being done abroad. As early as the year 1904 it is estimated that there were over 10,000 suction gas power plants in Germany alone. They had come into general use and were found in the finest hotels, stores, factories, etc., for electric lighting and other power purposes. The actual users of the plants were enthusiastic over the results.

That producer-gas power is a pronounced success in the United States is evidenced by the large number of satis-

this plant eighteen per cent of the total energy of the fuel is converted into useful work. (Varies according to conditions from fifteen to twenty-one and one-half per cent.) This means that a suction gas producer plant uses from one-half to one-fourth as much coal for a given amount of power as a steam plant.

A 150-horse-power suction producer plant, running two-thirds load, 3,100 hours per year, uses approximately one and one-half pounds of coal per brake horse-power per hour. (Tests have been made showing a consumption of less than one and one-quarter pounds at two-thirds load and less than one pound at full load.) With anthracite at $5 per ton the fuel alone costs $1,162.50 per year. Furthermore, the cost of attendance can be reduced materially with a producer plant, as the operator can spend part of his time in other useful work.

Much valuable information is given in the report of the United States Geological Survey concerning the fuel testing plant at the Louisiana Purchase Exposition, St. Louis, Mo. For three years the government experts conducted a series of tests on many samples of coal from mines all over the country. Briefly, the apparatus included a non-condensing Corliss engine steam plant with water-tube boiler and a pressure type producer with three-cylinder vertical gas engine.

From the summary of results obtained from a long series of tests, the fuel consumption in pressure type producer plant varied from 1.18 to 3.47 pounds per brake-horse-power per hour, the average being approximately one and three-quarters pounds. The average with the Corliss steam plant was found to be approximately four and one-half pounds, using similar fuels. With lignite the consumption in pressure producer plant was from 1.95 to 3.47 pounds, the average of five samples actually figuring 2.60 pounds. With Corliss steam plant using lignite the average consumption of "coal as fired" (not "dry coal") was approximately seven pounds.

Fig. 2 illustrates an exterior view and Fig. 3 a sectional view of a Fairbanks-Morse anthracite suction gas producer. All of the principal features are clearly shown. Coal is admitted to the producer through a hopper at the top. This has double closure, so that fuel can be introduced without at the same time admitting air. In the process of partial combustion which takes place producer gas is generated.

The hot gas passes through a vaporizer in which a small amount of steam is formed which, with a limited amount of air, passes under the grate of the producer. In the smaller sizes the vaporizer is at the top of the producer where it uses the waste heat from the escaping gas and where, at the same time, the water keeps the top from getting too hot. In the larger sizes the vaporizer is separate and connected to the producer by piping.

From the vaporizer the hot gas flows through the scrubber, which is merely a cylindrical-shaped tank filled with coke over which a spray of water is constantly sprinkled. The large contact surface of the coke effectually cleanses the gas of dust and impurities carried over from the producer, and also acts to cool the gas, which is essential in order to prepare it for use in the engine.

With certain fuels, especially when much tar is encountered, it is also necessary to add a sawdust purifier in order to abstract the last traces of tar from the gas. While not absolutely essential, yet it is always advisable to use a gas tank between the scrubber and the engine, in which a certain amount of gas is stored for ready use in the engine. This is especially desirable where the loads are variable.

In the care of the producer, the principal attention needed is to poke the fire every few hours, according to quality of the coal, in order to break up and remove clinkers, which would otherwise interfere with the making of sufficient gas. Poke holes are provided so that every part of the fire can be reached conveniently.

Anthracite in "buckwheat" or "pea" sizes, lignite, coke and charcoal are the fuels commonly used. In many sections these small sizes of anthracite can be bought cheaply in car lots. For example, in Chicago the car-load price of "buckwheat" anthracite is usually about $3.75 per ton. In some of the states west of Chicago the price varies from $5 to $7 per ton. At some points in southern

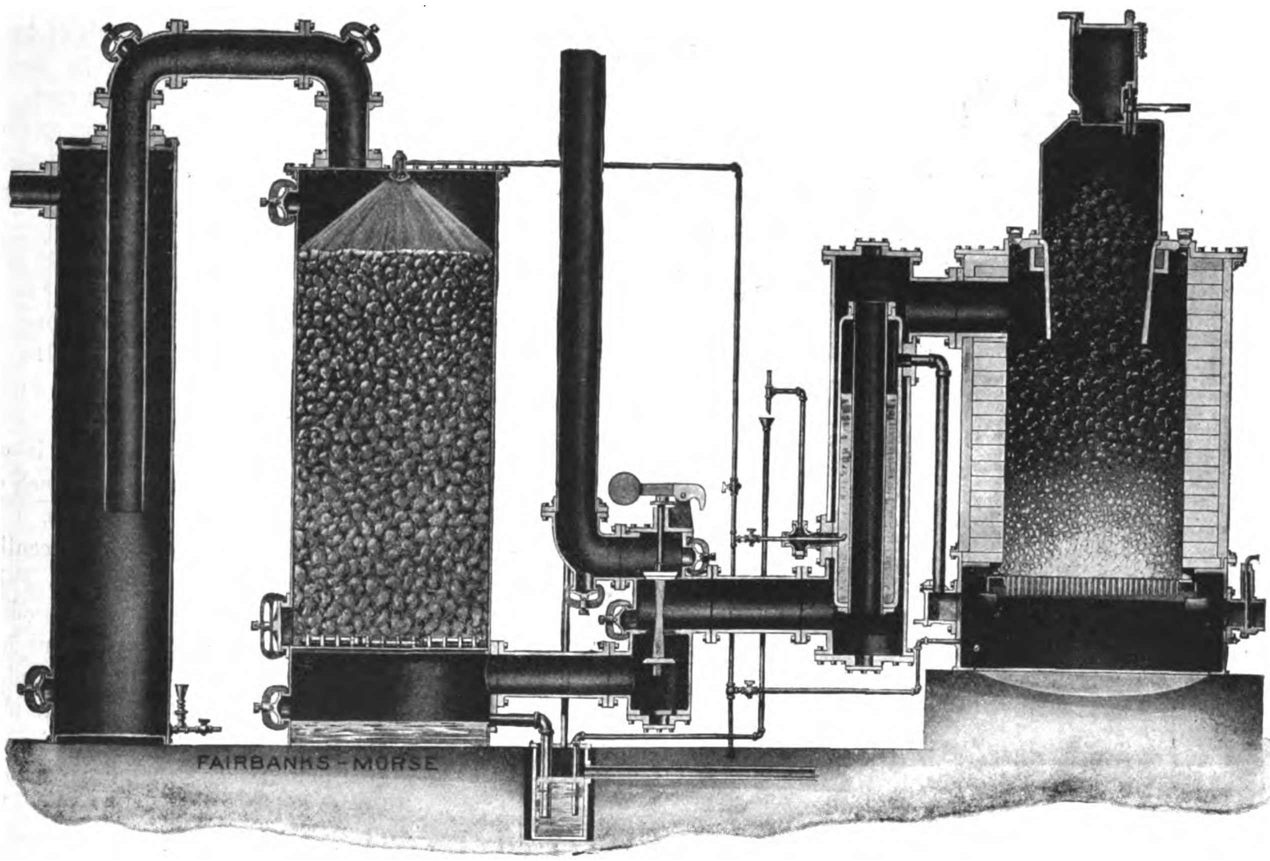

FIG. 3.—SECTIONAL VIEW OF FAIRBANKS-MORSE SUCTION GAS PRODUCER.

Canada these small sizes of Pennsylvania anthracite can be bought for from $3 to $4 per ton. In some of the eastern states, which are nearer the source of supply, the prices are even less.

The lignite producer offers a wonderfully cheap and reliable power in sections where this fuel is available. This can usually be had at a price of from $1 to $3 per ton. At Smithville, Tex., where a 150-horse-power lignite producer plant is installed, the cost is $1.70 per ton. Lignite is of little value for steaming purposes, mostly due to the large amount of moisture, but it makes a most excellent fuel for the producer and in some respects is easier to handle than anthracite.

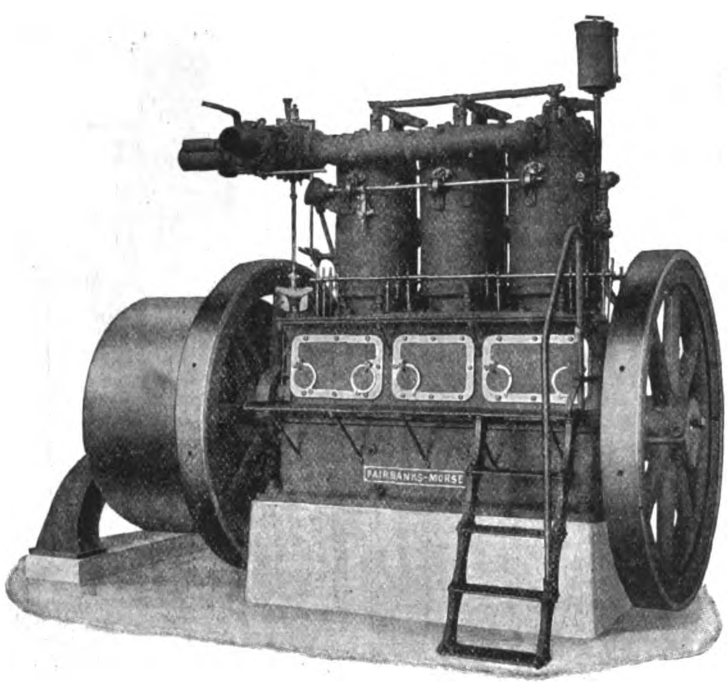

Fig. 4.—Multi-Cylinder Vertical Producer Gas Engine.

Coke and charcoal are economical fuels in some sections and can be used separately or mixed with anthracite.

Producer gas engines of the vertical type are made in sizes of 200 horse-power and smaller. By combining several units plants of 800 to 1,000 horse-power or larger have been installed. Fig. 4 illustrates a thoroughly modern Fairbanks-Morse engine of this type. It may be of interest to engineers to note briefly a few of the carefully developed features in the design of these engines.

The present system of ignition is a great improvement over the methods formerly used. The make-and-break igniter is so constructed that it can be adjusted to spark as early or as late as desired, when the engine is running or at rest, by means of a convenient hand lever. A single lever controls the time of ignition for all cylinders. This is a feature of much importance, especially with producer gas, as it permits timing the ignition to give the greatest possible power and economy with any particular grade of gas and when the engine is running. In addition, there is an independent adjustment for each igniter which is operated by drop cam.

Igniters can be removed, inspected and cleaned without interfering with other working parts, and they are located most conveniently. As the successful operation of a gas engine depends largely upon the igniter the value of these features can not be emphasized too strongly.

Both valves are mechanically operated from a single cam shaft, which is located inside the crank case. This minimizes the amount of noise, and furthermore the two-to-one reduction of gearing includes a pinion which is made of alternate layers of steel and red fibre. These features insure a quiet running engine.

The simple fly-ball governor is of a most carefully designed pattern. This operates a balanced disc valve which is so constructed that there is no frictional contact or surface to become fouled by any impurities in the gas. This is especially important with engines operating on producer gas. The governor insures very close regulation, adapting the engine for electric lighting and other service requiring uniform movement.

Lubrication is effected by means of a single elevated oil reservoir which is provided with separate brass pipe with individual sight feed for each bearing. This is a most effective system of engine lubrication and has been adopted as the best to be had. The drip from the different bearings collects in the base of the engine, which is drained by means of a small pump. The oil is run through a filter and is then used over again.

Each engine is fitted with a hand-operated speed regulator, by means of which speed can be reduced when the engine is running.

One cylinder of each engine is fitted with automatic compressed-air starting gear. This can be thrown into or out of action by the movement of a single lever, and the engine is started automatically on compressed air.

From report on fifty-horse-power plant used in operating marble works in Tennessee, statement is made that they use only eighteen ordinary hods of buckwheat anthracite per day of nine hours at a total cost of $1.39 for the coal. At this plant they poke the fire once in the morning before starting and once at night after shutting down. Outside of this the plant requires very little attention.

One of the largest suction gas producer plants in the United States comprises six 150-horse-power engines and one 200-horse-power engine—1,100 horse-power in all—complete with suction gas producers, using anthracite as fuel. This plant is in Wisconsin and is operated twenty to twenty-four hours each day, excepting Sundays and holidays.

A series of tests has recently been made on a 150-horse-power Fairbanks-Morse engine and anthracite producer, for continuous runs of twenty-four hours, at one-quarter load, one-half load, three-quarters load and full load, the object being to determine the comparative economy at different loads. The coal used was an ordinary grade of buckwheat Pennsylvania anthracite, running rather high in ash, the analysis being as follows:

Fixed carbon	78.9 per cent.
Volatile	5.3 "
Ash	13.0 "
Moisture	2.7 "
Sulphur	0.77 "
B.T.U. per pound as fired, 13,590.	

Some of the results of these tests, including the coal consumption per brake-horse-power-hour, are given below:

Load.	B.H.P. on Engine.	Speed. R.P.M.	Coal in 24 Hours.	Coal per B.H.P. per Hour.	Cooling Water per B.H.P. Hour. Gals.	Steam per pound of Coal. Lbs.
Full	149.4	224	3838	1.07	5.0	0.48
¾	113.1	226	3185	1.13	5.6	0.45
½	75.4	226	2369	1.3	6.8	0.41
¼	38.0	228	1590	1.74	13.1	0.35

A New Line of Cigar Lighters for Continuous and Intermittent Service.

Cigar lighters for both continuous and intermittent service are now being manufactured by the General Electric Company and may be obtained in the pendent, desk or table types. These cigar lighters are suitable for operation on either alternating or direct-current circuits and may be readily connected to any ordinary lamp socket.

For intermittent service, both the pendent and table types are available, but the pendent type only is suitable for continuous operation. Those for intermittent service are equipped with a push-button for closing the circuit during the period of operation, which is generally from four to six seconds. The continuous service lighters are normally left in circuit but have a small switch for turning the current off when not in use.

The heating unit is somewhat similar in appearance to the ordinary fuse plug, and for intermittent service consists of several lengths of coiled wire lightly cemented to a thin sheet of insulating compound. The ends of the wire are connected to terminal screws in the porcelain plug base which is screwed into a socket in the body of the lighter. A thin piece of perforated mica, placed in a metal cap fitted to the porcelain plug base, protects the heating coils. To light the cigar or cigarette it is only necessary to place the end against the perforated disc, the hot air, drawn through the holes in the mica, igniting the cigar even before the mica disc becomes red.

The intermittent desk type, as shown in the illustration, is compact and simple in design, the heating element being similar to that used in the intermittent pendent type.

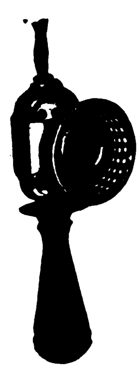
The construction of the plug for continuous service is similar to that for intermittent service, except that the coils of wire are completely filled with cement between turns. With this unit no mica covering is used, as a perforated insulating compound placed on the top of the heating unit conducts the heat to the cigar. As will be noted in the illustration, these plugs are surrounded by a perforated metal mouthpiece which protects the plug and also prevents the liability of any one being burned by coming in direct contact with the heating element. In this type of cigar lighter the heating plug can not be removed without the use of a special spanner. This feature is of special importance when the lighters are used in public places such as hotels, cigar stores, etc.

These cigar lighters are made for voltages from ninety-five to 125 volts. The power consumption is very low, being seventy-five watts for the intermittent type and twenty-five watts for the continuous type. The cost of operation and the life have been determined after a series of careful tests. It was found that with the intermittent type 1,000 lights

DESK OR TABLE TYPE CIGAR LIGHTER FOR INTERMITTENT SERVICE.

could be obtained at an approximate cost of one cent where power is sold for ten cents per kilowatt-hour. The continuous-service lighter can be operated at a cost of about three cents per day. The durability tests show that the intermittent type will give about 22,000 lights before deterioration of the heating element occurs. Tests now being conducted on the continuous-

PENDENT TYPE CIGAR LIGHTER FOR INTERMITTENT SERVICE.



PENDENT TYPE CIGAR LIGHTER FOR CONTINUOUS SERVICE.

service types show a maximum of over 5,000 hours at the present time. These tests are still in progress, so that this value will be exceeded.

The cigar lighters of the intermittent type are finished in oxidized copper, the continuous-service types being given a nickel-plated finish. All types are furnished with a suitable cord and attaching plugs.

The American Association of Electric Motor Manufacturers.

A meeting of the American Association of Electric Motor Manufacturers will be held at the Frontenac, Frontenac, N. Y., in the Thousand Islands, on September 9, 10 and 11. This association was organized at Hot Springs, Va., a few months since, the membership consisting of three classes, as follows: Class A, manufacturers of direct-current motors up to and including fifty horse-power; Class B, manufacturers of alternating-current motors up to and including fifty horse-power; Class C, manufacturers of all types of motors above fifty horse-power.

The following officers have been elected: President, S. L. Nicholson, Westinghouse Electric and Manufacturing Company, Pittsburg, Pa.; vice-president, Class A, C. F. McGilvray, Robbins & Myers Company, Springfield, Ohio; vice-president, Class B, R. J. Russell, Century Electric Company, St. Louis, Mo.; vice-president, Class C, F. S. Hunting, Fort Wayne Electric Works, Fort Wayne, Ind.; secretary, J. C. McQuiston, Westinghouse Companies' Publishing Department, Pittsburg, Pa. Executive committee: C. W. Holtzer, Holtzer-Cabot Electric Company, Brookline, Mass.; C. H. Roth, Roth Brothers & Company, Chicago, Ill.; B. C. Kenyon, Diehl Manufacturing Company, Elizabethport, N. J.; J. C. Hobart, Triumph Electric Company, Cincinnati, Ohio; James Burke, Burke Electric Company, Erie, Pa.; W. A. Layman, Wagner Electric Manufacturing Company, St. Louis, Mo.; J. W. Ham, General Electric Company, Schenectady, N. Y.; A. H. Whiteside, Allis-Chalmers Company, Philadelphia, Pa.; A. L. Doremus, Crocker-Wheeler Company, Ampere, N. J.

Business Getting with the Tungsten Lamp at Lowell, Mass.

J. H. Hunnewell, general superintendent of the Lowell (Mass.) Electric Light Corporation, is conducting an energetic business-getting campaign, using the rental of tungsten lamps and free wiring as his most important persuasions. General Electric tungsten lamps are being rented on a basis of twenty-five cents per month per lamp using 100-watt, eighty-candle-power, and the sixty-watt, forty-eight-candle-power sizes. The rental price includes the lamp, shade and holder and whatever pendent or fixture is necessary. The plan is working so successfully that at present there have been in the neighborhood of 700 lamps installed and the business is increasing rapidly.

Current Electrical News

DOMESTIC AND EXPORT.

POWER PLANT ON COOSA RIVER—A water-power development is proposed at Lock No. 2, on the Coosa River, near Gadsden, Ala. The company behind the scheme is the Coosa River Electric Power Company, of Anniston, Ala. Roswell H. Cobb, a banker of Anniston, is the president. A survey of the Coosa River at Lock No. 2 is being made by Captain Harley B. Ferguson and a corps of engineers for the purpose of securing data for the War Department in connection with the development of the proposed new company. It is planned to develop 30,000 horse-power. The next convening Congress will be asked for certain privileges in connection with this proposition.

LOUISVILLE RAILWAY COMPANY TO ISSUE NEW STOCK—Following the action taken at a meeting of the stockholders of the Louisville (Ky.) Railway Company, several months ago, authorizing an increase in the capital stock of the company, amended articles of incorporation have been filed by the company increasing the capital stock $500,000. The increase is for the purpose of reimbursing the Louisville Traction Company for funds advanced to the Louisville Railway Company several months ago. The new capitalization will be common stock, of a par value of $100. The articles of incorporation contain the names of T. J. Minary, president of the company; John Stites, Charles T. Ballard, Harry Bishop, Sam Casseday and Alex. P. Humphrey.

TO BUILD MONTANA ELECTRIC LINE—Articles of incorporation of the Billings & Cooke City Electric Railway Company have been filed. The capital stock of the organization will be $5,000,000, the principal place of business Billings and the terms of its legal existence forty years. The company will build and equip an electric railroad which will extend from Billings to Cooke City, Mont., passing through Laurel, Park City and possibly Columbus, up the Stillwater Valley to the mining camp. Those interested in the company are: J. B. Clayberg, of Helena; M. E. Estep, of Chicago, Ill.; E. M. Hosky, of Helena; George E. Savage, of Butte; Thomas Harney, of Galena, Ill., and A. L. Babcock, B. G. Shorey and Theodore Martin, of Billings.

MINNESOTA POWER PROJECT—The Backus-Brooks interests at International Falls, Minn., have sold their water-power holdings at the falls to eastern parties, and it is understood that the development hereafter will be carried on with capital furnished by the steel interests. W. H. Cook, president of the Duluth, Rainy Lake & Winnipeg road, has notified Minneapolis lumber interests that work will begin at once looking to the completion of works that will produce 30,000 horse-power within a year. This, it is understood, will be followed by the completion of new railroad lines in the district. It is understood that the Backus-Brooks company will concentrate its efforts upon the completion of a paper and pulp plant on the American side at International Falls. Pulp wood is plentiful in that locality, and the mill is to be finished by the time the power is ready to be delivered. The plant will have a capacity of 500 tons of paper a day.

CONSOLIDATION OF MEXICAN ELECTRICAL COMPANIES—It is announced that the Mexico Street Railway Company and the Mexican Light and Power Company are to be amalgamated, and one company is to control the light and power supply of Mexico City. Plans for the amalgamation are now being prepared, and a special stockholders' meeting of the light and power company will be called in the near future to arrange the details. The Mexican Light and Power Company was organized about two years ago as a consolidation of all the light and power companies in the city. There is a small power-house at Noanalco, while the main power plant is at Necaxa, on the state line between Hidalgo and Puebla, 100 miles east of Mexico City. The company is to build a second power plant near Necaxa. The stock of the company is held largely in Scotland and Germany. It is a Canadian concern. The Tranvias Electricas Mexicanas, or the street railway company, is a Canadian corporation, but the stock is owned largely by F. S. Pearson, of New York city. The company was originally largely British, Wehrner, Beit & Company, of London, owning a controlling interest. It was this company which sold out its interest to Pearson and his associates.

ELECTRIC LIGHTING.

LIMA, OHIO—The city council has passed an ordinance providing for a $105,000 municipal electric light plant.

NEWARK, N. J.—The local water company is considering the installation of machinery to furnish electric light to the village.

CANTON, N. Y.—The Canton Electric Light and Power Company has purchased land upon which it will erect a transformer substation.

BENBOW, ILL.—The Benbow village board has granted a twenty-year franchise to the Benbow City Light, Heat and Power Company. A $60,000 plant will be erected.

SAN BERNARDINO, CAL.—The Redlands Gas and Electric Company has applied for permission to run transmission lines over the county roads between this city and Redlands.

SPRINGFIELD, MASS.—The new power plant of the United Electric Company, which cost approximately $300,000, has been placed in operation, adding 3,000 horse-power to the company's capacity.

HUNTSVILLE, ALA.—Fred A. Howe, a business man of this city, has secured a franchise from the city council of Gurley allowing him to establish and operate an electric light and power plant in that town.

CENTER, TEX.—Fire on August 13 destroyed the electric light plant, planing mill and 150,000 feet of lumber belonging to Redditt, Fleshman & Hardrider. There was no insurance and the loss is about $150,000.

BUCYRUS, OHIO—The Bucyrus city council has decided to build a municipal lighting plant. The proposition means the investment of $90,000. Bonds will be issued to cover the cost and the plant will be started at once.

ELWOOD, IND.—The sale of all property of the Citizens' Heat and Light Company has been ordered by Judge Greenlee, of the Superior Court. The sale will be made by the receiver, the Elwood Trust Company, at the court-house on September 18.

DODGEVILLE, WIS.—The Dodgeville Electric Light and Power Company will build a plant on the railroad land just south of the Illinois Central passenger station. The building will measure forty by seventy feet. It is likely that a heating plant and an ice plant will also be operated.

FREEHOLD, N. J.—David H. Smith, of Jamesburg, as receiver of the Manalapan Light Company, sold the property of that corporation at public sale to W. J. Lansley, of Perth Amboy, the promoter and one of the largest creditors of the concern, on a bid of $500. There is $25,000 worth of bonds outstanding.

OLYPHANT, PA.—Five prominent business men of Olyphant have been appointed by the borough council to operate the municipal lighting plant. There has been a movement to sell or lease the plant. It was claimed that the borough would have to issue $15,000 worth of bonds to put the plant in good shape.

DANVILLE, PA.—The borough council has decided to grant a franchise to C. F. Kloss and Joseph M. Watts, promoters of a new electric light company which purposes to transmit to this city electricity generated on the West Branch of the Susquehanna, the plant to be in operation within two years of the granting of the franchise. The company will furnish light to business places at a rate not to exceed six cents per kilowatt-hour and to private residences at a rate not to exceed eight cents per kilowatt-hour.

DOVER, N. J.—The new ten-year street lighting contract with the Dover Electric Light Company has been signed by the mayor, town clerk and the officials of the electric light company. The agreement requires the town to use at least seventeen arc lamps at $85 each and 240 incandescent lamps at $17 each a year.

LOGANSPORT, IND.—Professor J. Walter Esterline, of Purdue University, who has been preparing plans for a municipal light plant for Logansport, has completed his work and submitted his report. The plans call for the expenditure of $39,540, and an ordinance has been passed by the city council appropriating this amount.

HARTFORD, WIS.—The city is preparing the site of the municipal electric light plant for the erection of the building by moving the Raaschke House. The work of putting up the power-house will be commenced as soon as the contracts are let, which will be in a short time. City Engineer Maltby has completed work on the plans.

BATH, N. Y.—C. K. Tower, of the Citizens' Electric Service Company of Bath, which has had its application for permission to build a new electric power and light plant here granted by the Public Service Commission, states that the company will proceed at once to build its power plant and to do the necessary wiring for the street lighting service.

BARNESVILLE, GA.—The city council has accepted the contract for the installation of the new electric light plant, and the new machinery will be shipped and set up within the next fifty days. The city has twice outgrown its plant, and larger generators, electric and water machinery were required. The cost of the new equipment will be about $7,000.

ALBANY, ORE.—Articles of incorporation have been filed for the Lebanon Electric Light and Water Company, which will henceforth own and operate the light plant and water system in Lebanon. The incorporators are S. P. Bach, Samuel M. Garland, J. C. Mayer, P. M. Scroggins and S. I. Stewart. All of the incorporators except Mr. Stewart are residents of Lebanon.

SAN ANGELO, TEX.—Al Reynolds, of Oklahoma, announces his intention of applying to the city council for a franchise for an electric light system in San Angelo. He represents an Ohio company, and states that if a franchise is obtained the company will expend $150,000 on the plant, which he will manage. Mr. Reynolds is superintending the electric work on the street-car system.

HASTINGS, NEB.—A report has been made by the city treasurer showing that the city electric lighting plant, since it was established by the city in 1901, has twice paid for itself. The city during that time has saved $56,000 in street lighting alone, while the profit on lighting private residences and business concerns has been sufficient to not only maintain the plant, but also to make numerous extensions and install new machinery from time to time. There is a balance of $12,000 now to the credit of the lighting fund.

HICKORY, N. C.—A meeting of the citizens of Hickory was held recently for the purpose of submitting the proposition of developing the water power at what is known as the Horseford Shoals on the Catawba River, two and one-half miles from Hickory. A stock company was organized a few weeks ago to develop this power and engineers employed to make surveys. It is considered possible to develop 6,000 horse-power at a minimum cost owing to the adaptability of the site for such development. All the stock necessary, with the exception of $20,000, has been subscribed to develop 3,500 of the 6,000 horse-power available.

IOWA CITY, IOWA—Franklin Benjamin, of Galesburg, Ill., the new owner of the American Cereal Company's plant at Coralville, proposes to take on the Iowa City municipal contract to light the city with electricity and gas. He desires to build an electric light plant at Coralville and a gas plant in Iowa City. Mr. Benjamin offered the city council the entire equipment of the electric light plant, as a bonus, after twenty-five years, the gift of the poles, wires, equipment, etc., being limited to sufficient to supply the city's needs, as they stand at the end of twenty years. If the city prefers Mr. Benjamin agrees to deposit $1,000 a year in a bank (he to draw the interest thereon), and at the end of the twenty-five years the $25,000 is to go to Iowa City if he retains the plant.

ELECTRICAL SECURITIES.

For a brief period, early in the week, it appeared as if there might ensue a break in prices, due to the bewildering turn affairs had taken when in a terrific effort to bear the market one large brokerage firm brought down suspension from the Stock Exchange upon its head. The heavy interests, however, were able to meet the raid and prices were maintained, with everything proceeding in a most orderly manner all through the week. The most favorable indications at present are the feeling of general hopefulness for an early activity in business, the excellent condition of freight railroads to cope with any reasonable improvement in tonnage, the little real damage suffered through storm and flood by the crops, and the large surplus being stored up in banks all over the country—in fact, all over the world, as is reflected in recent reports.

Dividends have been declared upon the following electrical securities: Louisville (Ky.) Railway Company; semiannual dividend of 2½ per cent on the preferred and a quarterly dividend of 1 per cent on the common, payable October 1. Galveston-Houston (Tex.) Electric Company; semiannual dividend of $3 per share on the preferred stock, payable September 15. General Electric Company; regular quarterly dividend of $2 per share, payable October 15 to stock of record September 9. Rochester (N. Y.) Railway and Light Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable September 1. Mackay Companies; regular quarterly dividends of 1 per cent on the preferred and 1 per cent on the common, payable October 1 to stock of record September 12. Northern Ohio Traction and Light Company; two quarterly dividends of ¼ of 1 per cent each, payable on the $8,938,900 capital stock on September 15 and December 15, 1908, to holders of record September 1 and December 1, respectively. This reduces the annual rate to a 1 per cent basis, comparing with a 2 per cent rate maintained from June 15, 1906, to June 15, 1908.

NEW INCORPORATIONS.

CLEVELAND, OHIO—Buffalo Valley Telephone Company, Cumberland. $1,000.

DENVER, COL.—Municipal Lighting Company. Incorporators: Carl Christensen and Carl Vogt. $100,000.

NEWARK, N. J.—Arcade Block Lighting Company, Newark. To manufacture electricity, etc., for light, heat and power; fixtures, etc. $40,000. Incorporators: J. O. Sharpe, T. A. Phillips, F. J. Greenberg, Newark.

PERSONAL MENTION.

MR. WALTER P. SCHWABE has resigned as superintendent of the Rutherford (N. J.) office of the Public Service Corporation of New Jersey.

MR. W. D. SHALER has been elected secretary of the Doubleday-Hill Electric Company, Pittsburg, Pa., to fill the place made vacant by the decease, recently, of his brother, Mr. H. G. Shaler.

OBITUARY NOTE.

MR. JOHN JAMES GREENOUGH, inventor and former superintendent of the Patent Office at Washington, died recently at the home of his daughter in Brookline, Mass. He was the first to take out a patent on a sewing machine, invented the first shoe-pegging machine and assisted in the construction of the first electric locomotive. He held the position of superintendent of the Patent Office from 1837 until 1841. In 1853 he commenced the publication of the *American Polytechnic Journal*. He was born in Boston, January 19, 1812.

ELECTRIC RAILWAYS.

HUNTSVILLE, ALA.—The city council has granted Ed. L. Pulley and associates a franchise to construct and operate an electric car line.

RIVERSIDE, CAL.—The Riverside & Arlington Railway Company has been granted a franchise by the city council. This includes a freight-carrying privilege.

SALT LAKE CITY, UTAH—The Utah Light and Railway Company is planning extensions of its lines throughout Salt Lake and Utah valleys and as far south as Provo.

PITTSBURG, PA.—The Pittsburg & Beaver Street Railway Company, which proposes to construct a line from Pittsburg to Beaver on the populous south side of the Ohio River, has increased its capital from $60,000 to $235,000.

YAZOO CITY, MISS.—A street railway is now assured for Yazoo City. The bonds which were issued about a year ago have been signed and delivered and the money paid over to the city treasurer. In ninety days it is thought the road will be in operation.

BLOOMINGTON, ILL.—General Manager Fischer, of the Illinois Traction System, is authority for the statement that in two years' time the traction system will be connected with Terre Haute and extended on into Indiana, transferring to the Indiana interurban lines.

DUNKIRK, N. Y.—The Buffalo & Lake Erie Traction Company has awarded to Peter B. Colgan, of this city, the contract for excavating and clearing the roadbed for trolley extension from Cassity's Woods to Sheridan to connect with the main line from the belt line system.

ALBANY, N. Y.—The Public Service Commission, Second District, has granted the application of the Western New York & Pennsylvania Traction Company for permission and approval to construct an extension of its road in the village of Salamanca to and into the village of Little Valley.

SALISBURY, N. C.—The Piedmont Electric Car Line Company, of this city, has been granted a franchise to build an electric line skirting Salisbury on the north and west, the work to begin within six months. The same company proposes to connect Spencer and East Spencer by an electric line.

MOBILE, ALA.—Within sixty days engineers will begin work surveying the proposed route of the electric line from Citronelle to Mobile, and inside of one year cars will be operating into Mobile from Citronelle, according to George S. Bressler, of Gulf Crest, Ala., who is interested in the proposition.

DUNKIRK, N. Y.—A syndicate of Buffalo capitalists is said to be planning the construction of the long-awaited Cassadaga Valley trolley line over the proposed route from Dunkirk as far south as Sinclairville. According to the report, the new trolley line will take in all the villages down the Cassadaga Valley, including Stockton.

CHILLICOTHE, OHIO—The Scioto Valley Traction Company is completing the work of extending its line to the business section of Chillicothe. The overhead work is now being put up, and within a short time the company will be operating cars from Columbus to the business district of the city.

WASHINGTON, PA.—Burgess A. V. Lewis, of Donora, has returned to the council with his signature the ordinance granting a franchise to the Donora-Eldora Street Railway Company. The company has thirty days in which to file its bond of $5,000, three months in which to start work and one year in which to complete the road from Donora to Eldora.

HUNTSVILLE, ALA.—The question of building an electric railway from this city to Monte Sano is being agitated. Several business men have secured eighty acres of land on the top of the mountain and it will be divided into 200 lots and sold. The funds realized from this sale will be used as a nucleus with which to push the electric railway project.

BERKSHIRE, MASS.—The Berkshire Street Railway Company has petitioned the State Railroad Commission for authority to issue $80,000 additional capital stock, $40,000 each for extensions in Pittsfield and improvements to the line between North Adams and Williamstown. With the petition of April 28 this would make $365,000 new stock. The market value is fixed at $100 per share.

NORTH VANCOUVER, B. C.—At a meeting of the district council, at which there were present Acting General Manager T. W. Glover and Local Manager W. B. Bunbury, of the British Columbia Electric Railway Company, arrangements were completed for the extension of the lines of the company up Capilano Valley to the second cañon. The line will be in operation next spring.

HOUGHTON, MICH.—The Houghton County Traction Company, of Houghton, Mich., has contracted with the Stone & Webster Engineering Corporation for the extension of its lines from Wolverine to Mohawk, Mich. The contract includes the construction of the track, bridges, overhead work, a car barn, a small substation and the purchase of some new cars. The work as planned will cost about $125,000.

SEYMOUR, IND.—The Seymour & Brownstown Construction Company has been organized to construct an electric railway between Seymour and Brownstown, a distance of twelve miles. Indianapolis and Marion men are interested with local men in the enterprise. The company has asked for right of way through this city. The proposed line will connect with the Indianapolis & Louisville traction lines in Seymour.

MARQUETTE, MICH.—According to the officers of the Marquette, Negaunee & Ishpeming Interurban Railway Company, an active start will be made with the grading of the right of way between this city and Negaunee within the next few weeks. Some work has already been done at the Marquette end of the right of way. The operations now projected, however, are to be carried out on a large scale, and it is hoped that they will result in having the line ready for traffic by June of next year.

NEW CASTLE, PA.—The Mahoning & Shenango Railway and Light Company has secured the passage of an ordinance extending its franchise thirteen years, making it expire in twenty-five years. For the extension the company gives a rate of twenty-five tickets for $1, universal transfers and a partial guarantee of better service. It also agrees to extend the transfer and city fare. The present traction franchises have a life of twelve years, and on the Park and Falls line there is a fare of twenty-seven tickets for $1. On other lines the fare is twenty-two tickets for $1.

MINNEAPOLIS, MINN.—Articles of incorporation of the Electric Short Line Railroad Company have been filed. The principal place of business is given as Minneapolis. The incorporators are: Severen Solverson, who is secretary of the Phoenix Loan and Investment Company; E. C. Hinde, of Sioux Falls, S. D.; Frank E. Reed, of Glencoe. In order, they hold the offices of president, vice-president, and secretary. It is stated that the purpose is to put in good form the properties of an organization which has been in existence for five years, and that the incorporation has no significance as to any immediate activity of the company in railroad building.

BUTLER, PA.—Surveys of a route for an electric line projected by Butler, Pittsburg and Franklin capitalists to connect Butler and Conneaut Lake have been begun. The proposed line will be seventy miles long and will form the conecting link between Pittsburg and Erie and Buffalo by trolley. It is asserted that the backers of the venture are friendly with the interests owning the Pittsburg & Butler Street Railway Company. The route already selected from Butler is by way of Oneida, Queens, Euclid, Slippery Rock, Grove City, Greenville, to Conneaut Lake, with a branch to Franklin to connect with the Oil City line. From Conneaut Lake to Erie is a continuous line over the roads through Saegertown and Cambridge Springs to Erie and Buffalo.

SAN JOSE, CAL.—The Southern Pacific Company has purchased from L. S. Hanchett, of San José, the Santa Clara Interurban Railroad Company's property, including rights of way for a railway between Santa Clara and San Mateo. The purchaser intends to build at once and to operate an electric railway between Santa Clara and San Mateo, thus giving San José electric railway connection with San Francisco. The rights of way purchased by the Southern Pacific constitute a private property. The Santa Clara Interurban Railroad Company built and equipped the electric railway system in Palo Alto. This system, including a power-house and all the tracks, rolling stock and other property connected with it, was purchased by the Southern Pacific. The estimated value of this property is about $500,000. The Southern Pacific proposes to build first between Santa Clara and San Mateo. Between Santa Clara and Palo Alto the route of the private right of way is along the county road. It is not stated just when the construction of the first portion of the road will begin, but it will be at an early date. Later the line will be extended between San Mateo and San Francisco. For this line the route of the old steam line by Mission Hill, that was in use by the Southern Pacific before the building of the Bay Shore cutoff, will be utilized.

DATES AHEAD.

Pennsylvania Electric Association. First meeting, Eagles' Mere, Pa., September 8-9.

American Association of Electric Motor Manufacturers. Next meeting, Frontenac, N. Y., September 9-11.

Association of Edison Illuminating Companies. Annual meeting, Lenox, Mass., September 15-17.

Colorado Electric Light, Power and Railway Association, Glenwood Springs, Col., September 16-18.

Arkansas Association of Public Utilities Operators. First annual convention, Little Rock, Ark., September 17-18.

Old Time Telegraphers' and Historical Association, and Reunion of Military Telegraphers, Niagara Falls, N. Y., September 16-18.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 5-6.

Kansas Gas, Water, Electric Light and Street Railway Association. Annual meeting, Pittsburg, Kan., October 8-10.

American Street and Interurban Railway Association. Annual convention Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annal convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

Railway Signal Association. Next meeting, Chicago, Ill., September 8. Annual meeting, Washington, D. C., October 13-15.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Order of the Rejuvenated Sons of Jove. Annual meeting, Buffalo, N. Y., October 15-16.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October 20-23.

EDUCATIONAL NOTE.

EVENING TECHNICAL COURSES AT THE POLYTECHNIC INSTITUTE OF BROOKLYN—The Polytechnic Institute, of Brooklyn, N. Y., announces evening technical courses in its College of Engineering for the season of 1908-1909. There will be a series of evening and Saturday courses in engineering, chemistry, physics, mathematics, drawing, history, economics and languages, especially designed to afford men in active practice opportunities for professional study. The term of study begins on Thursday, October 1, and continues until the various courses are completed. These courses may be taken independently or in connection with the regular work of the courses in engineering leading to the degrees of civil engineer, electrical engineer, mechanical engineer, chemical engineer or bachelor of science in chemistry.

NEW PUBLICATIONS.

THE STUDY OF SCIENCE BY YOUNG PEOPLE—A very interesting paper, entitled "The Study of Science by Young People," by Dr. William S. Franklin, of Lehigh University, has been reprinted from the proceedings of the twelfth annual meeting of the New York State Science Teachers' Association.

BIBLIOGRAPHY OF ELECTROCHEMISTRY AND ALLIED SUBJECTS—A bibliography of electrochemistry and allied subjects has been prepared by P. F. Mottelay. This compilation constitutes Appendix I of the author's "Bibliographical History of Electricity and Magnetism," which will shortly appear in book form.

INSTITUTION OF ELECTRICAL ENGINEERS—The *Journal of the Institution of Electrical Engineers*, of Great Britain, published under the supervision of the editing committee, and edited by George C. Lloyd, secretary, has been published by the house of E. & F. N. Spon, 57 Haymarket street, London, S. W. The New York publishers are Spon & Chamberlain, 123 Liberty street. The present volume contains the proceedings of March 19 and April 2, 9, 23 and 30. There are published as a supplement the accessions to the library from January 1 to June 30, 1908.

INDUSTRIAL ITEMS.

FOX BROTHERS & COMPANY, 126 Lafayette street, New York city, have published a handsome series of bulletins devoted to "Polar" flaming arc lamps, "Carbone" lamps, "Radiante Economy" and "Radiante" lamps, standard show-window lighting, technical data, and tungsten incandescent lamps.

THE HOLOPHANE COMPANY, New York city, in the August issue of "Holophane," makes an interesting special announcement concerning the Holophane D'Olier metal reflector. The Holophane Company has acquired, and will hereafter have exclusive control of, the metal reflectors designed by, and manufactured under the patents of, Henry D'Olier, Jr.

THE GENERAL ELECTRIC COMPANY, Schenectady, New York, has issued bulletin No. 4,597, devoted to Thomson astatic instruments for continuous-current switchboards. Bulletin No. 4,575 is devoted to Type F, Form K-7 oil-break switches. Bulletin No. 4,596 is devoted to enclosing globes for arc lamps. Copies of this bulletin will be furnished to those interested upon request.

THE ROCKWELL FURNACE COMPANY, New York city, has published two handsome catalogues devoted, respectively, to portable heaters for heating work which is too bulky or inconvenient to remove to a furnace, and where it is desirable to take the heater to the work, such as annealing, hardening, expanding, bending, brazing, skin-drying, lead melting and rivet heating; and to melting furnaces for melting all metals, tinning, galvanizing, tool hardening, and all operations requiring molten metal and other heated baths.

THE CONSOLIDATED ELECTRIC LAMP COMPANY, Danvers, Mass., announces that although its main factory and stock were seriously damaged by the fire which occurred on August 14, it is in a position to take care of orders from its Pine street factory. The company has already perfected plans for a larger and thoroughly equipped building, to be completed before the winter sets in. As the fire occurred in the quiet season, the company was not so greatly inconvenienced as it otherwise would have been. The loss caused is estimated at $20,000, partially covered by insurance.

THE BRISTOL COMPANY, Waterbury, Ct., is issuing two new bulletins, No. 91 and No. 93, which, with bulletin No. 92, cover the list of Bristol recording thermometers for all temperature ranges up to 800 degrees Fahrenheit. As a result of the consolidation of the business of William H. Bristol with that of the Bristol Company the latter company also manufactures William H. Bristol electric pyrometers together with the three classes of recording thermometers, which are described in the bulletins above mentioned. Copies of these bulletins will be furnished to those interested upon request.

THE TRIUMPH ELECTRIC COMPANY, Cincinnati, Ohio, has published a little brochure entitled "The Way to Forget." After treating the subject in a rather airy fashion the reader is made acquainted with the fact that the best way for a manufacturer to forget is to select everything in the plant, from the motor to the manager, of a character that will not, under ordinary conditions, do anything but the work intended. The only way to avoid experiences that create unforgettable memories is to get the right sort of a motor. The suggestion is, of course, that the right motor or dynamo is built by the Triumph Electric Company.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing its new bulletin describing the P.-A. electrically operated remote-control switch for use in controlling lights and power from a distance. A full description is given of the switch mechanism, together with some of the various applications. The company is also distributing bulletin No. 10, illustrating and describing the "O. K." fuse block cover, for use by central stations in preventing theft of current. This block is manufactured to fit standard size Edison plug fuse blocks. A flier is also being distributed, illustrating and describing the type "B" oil switches for entrance and motor service. This switch has been designed to meet the demands for a small-capacity medium-priced oil switch for use in connection with motor and lighting circuits up to and including 3,300 volts.

THE BELDEN MANUFACTURING COMPANY, Chicago, Ill., has issued catalogue No. 4, in convenient pocket size. This catalogue contains 124 pages, is printed on fine paper, and is profusely illustrated. Great pains have been taken to procure a simple and comprehensive book on wires, cables, cordage and other electrical raw material required, particularly by users of wire. Each article listed is described and illustrated with half-tone engravings wherever possible, showing the construction and the manner in which it is prepared for shipment. A feature of special interest to electrical supply dealers is the putting up in paper cartons of such products as will permit. Annunciator wire, gas-fixture wire, resin-core solder and table push-button cords are put up for shipment in neat paper cartons. In the back of the book there are twenty-five pages devoted to wire tables and formulas useful in the design of electromagnets, resistance coils, cables, etc. Copies of this catalogue will be sent to those interested upon request.

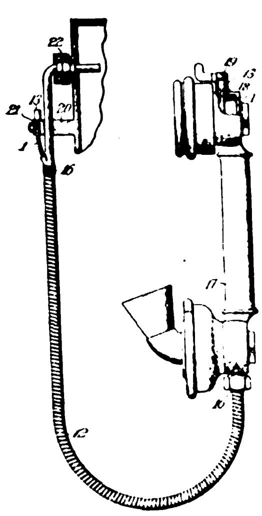
Record of Electrical Patents.

Week of August 18.

896,700. ELECTRICAL CONDUCTING CORD. George F. Atwood, East Orange, N. J., assignor to Western Electric Company, Chicago, Ill. A metal-armored cable arranged upon a strand of high tensile strength for a microphone telephone instrument.

896,705. PROCESS FOR HARDENING TANTALUM. Werner von Bolton, Charlottenburg, Germany, assignor to Siemens & Halske A. G. The process consists of heating tantalum in the presence of carbon.

896,715. FORMING OF FILAMENTS OUT OF VISCOSE OR SIMILAR VISCOUS MATERIAL. Charles A. Ernst, Lansdowne, Pa., assignor to Silas W. Pettit, Philadelphia, Pa. The cellulose xanthate is partly dissolved without precipitation in an alkaline solvent and then spun in a neutralizing solution.



896,700—ELECTRICAL CONDUCTING CORD.

896,738. REGULATOR FOR DYNAMOELECTRIC MACHINES. William C. Mayo and John Houlehan, El Paso, Tex., assignors of one-third to George E. Briggs, Barstow, Tex. A mechanical power regulator and a solenoid attachment for varying the effect of the superimposed current.

896,740. ELECTRIC TRACK BRAKE. William C. Mayo, El Paso, Tex., assignor, by direct and mesne assignments, of two-thirds to himself, and George E. Briggs, Barstow, Tex., and one-third to John Houlehan, El Paso, Tex. The electromagnet operates the brake shoe.

896,749. ELECTROCHEMICAL CONCENTRATION OF LIQUIDS. George W. Nistle, North Muskegon, Mich., and Robert L. Gifford, Chicago, Ill. The electrochemical effect concentrates the liquid.

896,752. MALTING PROCESS. Alfred Oertel, Godesberg, Germany, assignor to Diechmann & Cie., Cologne, Germany. The grain is subjected to the action of dark electric rays.

896,754. ELECTRIC SNAP SWITCH. Johann G. Peterson, Hartford, Ct., assignor to the Arrow Electric Company, Hartford, Ct. A quick-break push-button switch.

896,755. HORSE-POWER-HOUR METER. Johannes Picht, Halle-on-the-Saale, Germany. The current is varied through one coil in proportion to the pressure in the engine cylinder and through another coil in proportion to the speed of the engine.

896,764. CIRCUIT-BREAKER CONTACT. William M. Scott and Harry C. Campion, Jr., Philadelphia, Pa.; said Campion assignor to said Scott. The contact has an active member and an inactive member connected by a reinforcing electro plate.

896,784. NON-SYNCHRONOUS RECEIVING PERFORATOR. Milton T. Weston, New York, N. Y. The perforating hammer is alternately engaged and freed by electromechanical means.

896,793. ANNUNCIATOR. Edward Baum, Baltimore, Md. A combination of a visual and auditory signal.

896,796. TELEPHONE APPARATUS. Sidney A. Beyland, Elyria, Ohio, assignor to the Dean Electric Company, Elyria, Ohio. A tubular metal desk stand and support.

896,802. ELECTRODE FOR LIGHTNING ARRESTERS. Frank B. Cook, Chicago, Ill. The carbon block is finished with rough protrusions, between which is embedded a non-conducting, adhesive mixture.

896,808. RELAY. Frank L. Dodgson, Buffalo, N. Y., assignor to General Railway Signal Company, Buffalo, N. Y. The cores have enlarged and rectangular-shaped ends or poles, and means are provided for securing the cores to the carrying plate.

896,809. RELAY. Frank L. Dodgson, Buffalo, N. Y. Two permanent magnets are pivoted so as to swing in a plane at right angles to the cores of the electromagnet.

896,811. METALLIC FILM FOR USE WITH STORAGE-BATTERY ELECTRODES AND PROCESS OF PREPARING THE SAME. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to Edison Storage Battery Company, West Orange, N. J. Nickel or cobalt films with minutely roughened or matted surfaces are provided for admixture with the active material.

896,812. STORAGE BATTERY. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to Edison Storage Battery Company, West Orange, N. J. The supporting plate is fitted with a plurality of tongues which may be bent so that the pockets of active material may be separately removed from the plate.

896,828. SELECTIVE MECHANISM FOR TESTING DEVICES. Albert B. Herrick, Cleveland, Ohio. Plug connections are made through the medium of a punched disc and corresponding terminals, and the circuit-closing switch is interlocked with the disc.

896,830. TELEPHONE METER. Newman H. Holland, Brookline, Mass., assignor to Charles Bate, Boston, Mass. The registering meter is actuated in response to the closure of the telephone circuit at one station prior to the insertion of the plug and again upon the change in character of the current.

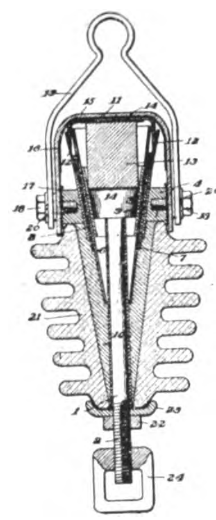
896,831. SIGNALING. Mark H. Hovey, Buffalo, N. Y., assignor to General Railway Signal Company, Buffalo, N. Y. A single signal-controlling circuit actuates a lock-controlling circuit, lock, track relay and signal.

896,832. SELECTIVE CALL APPARATUS. John A. Hullt, Topeka, Kan. A balance bar, actuated by a main lever, is adapted to throw off the holding pawl, co-operating with a ratchet selectively arranged for preventing the balance bar from throwing off the holding pawl.

896,836. TELEPHONE SYSTEM. John J. Kelly, St. Louis, Mo. Means are provided for signaling the central exchange without affecting the signal devices at the exchange.

896,838. ELECTRICAL APPARATUS. Charles J. Klein, New York, N. Y., assignor to Ralph Abraham Schoenberg, New York, N. Y. A water-tight floor receptacle.

896,839. ALARM SYSTEM AND APPARATUS. John M. Latimer, Flushing, N. Y., assignor to the Consolidated Fire Alarm Company, New York, N. Y. A closed-circuit system which operates upon interference with the normally grounded condition.



896,934.—INSULATOR.

896,840. ALARM TRANSMISSION. John M. Latimer, Flushing, N. Y., assignor to Consolidated Fire Alarm Company, New York, N. Y. A combination of rotating main character and supplemental character contacts actuated by a driven spring.

896,842. RAILWAY SIGNALING APPARATUS. William Macomber, Buffalo, N. Y., assignor to General Railway Signal Company, Buffalo, N. Y. Means are provided for forcing a signal to normal and holding the signal locked.

896,868. ELECTRICAL CLUTCH OR THE LIKE. Abram P. Steckel, Buffalo, N. Y. Oppositely disposed magnetized poles are provided in the opposing clutch members.

896,874. HOT-BOX INDICATOR. Henry Williams, Chicago, Ill. A fulminating cap actuates a contact-making device upon heating.

896,882. VIBRATORY MASSAGE DEVICE. Asa H. Arnold and Albourne F. Furbush, Poughkeepsie, N. Y. The vibratory movement is provided by the reciprocal action of the armature.

896,886. CONSTRUCTION OF ELECTROMAGNETS. Arthur F. Berry, Ealing, England. The magnetic circuit is built up of plates having axially parallel limbs connected together to embrace the inner and outer peripheral surfaces and inner end of the winding.

896,921. TORPEDO BOAT. Edward J. Kelley, Washington, D. C., assignor of one-eighth to Robert L. Nutt and one-sixteenth to Robert A. Hutchins, Jr., Portsmouth, Va. Means are provided for steering the torpedo, for actuating a visible signal, and for changing the color of the signal from a distant point.

896,930. ALARM CLOCK. Elijah McComb, Johannesburg, Transvaal. The alarm clock, cells and actuating mechanism are fitted in a cabinet with a hinged door.

896,934. INSULATOR. John P. Nikonow, East Pittsburg, Pa. The core is provided with an enlargement and a collar surrounding the enlargement, and a rain-proof insulating cap.

896,935. ARC LAMP. Ludvik Ocenasek, Prague, Austria-Hungary. As the end of a fusible pin is melted, the carbon is fed downward.

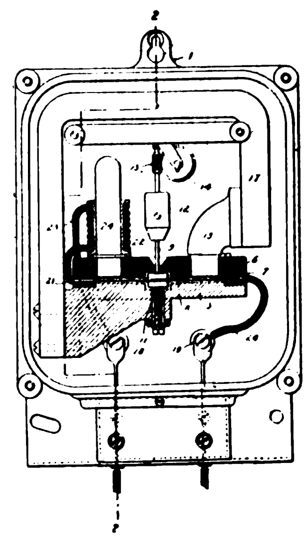
896,951. SOLDERING MACHINE FOR COMMUTATORS. Harry Stone, Wilmerding, Pa., assignor to the Westinghouse Air Brake Company, Pittsburg, Pa. The soldering tool is provided with a grooved surface, and is held in a heated receptacle equipped with means for rotating.

896,973. CHARGING SYSTEM FOR STORAGE BATTERIES. Fred B. Corey, Schenectady, N. Y., assignor to General Electric Company. An automatic switch is adapted to connect the batteries alternately to a charging conductor or to a discharging device.

896,979. FIELD REGULATION FOR MOTOR-GENERATORS. Charles E. Eveleth, Schenectady, N. Y., assignor to General Electric Company. Means are provided for simultaneously varying the speed of the motor and the field strength of the generator.

896,980. RECTIFIER PANEL. Samuel Ferguson, Schenectady, N. Y., assignor to General Electric Company. Two panels are provided on standards, one containing the rectifier apparatus and the other the circuit-connecting and measuring devices.

896,983. TRANSFORMER-CORE CONSTRUCTION. John J. Frank, Schenectady, N. Y., assignor to General Electric Company. The lamina are interleaved at the joints, and a portion of the lamina has notches located dissymmetrically at the interleaving ends.



896,999.—METER.

896,984. CONDUIT FOR ELECTRIC WIRES. Horace C. Freeman, St. Paul, Minn. A trough and a plurality of removable cover sections.

896,993. CONTROL SYSTEM FOR MOTOR-DRIVEN RECIPROCATING DEVICES. Leopold Janisch, Berlin, Germany, assignor to General Electric Company. The reciprocal motion of the motor is controlled between predetermined points.

896,999. METER. William J. Lloyd, Rugby, England, assignor to General Electric Company. The meter is equipped with a receptacle containing a conducting liquid.

897,013. METHOD OF GENERATING AND DISTRIBUTING ALTERNATING CURRENTS. Edward B. Raymond, Schenectady, N. Y., assignor to General Electric Company. Means are provided for deriving alternating current by driving the machine by mechanical power at a speed in any direction so that it runs greatly in excess of the speed corresponding to synchronism with the exciting current.

897,019. ELECTRIC CLOCK MECHANISM. George H. Rupley, Schenectady, N. Y., assignor of one-half to Frank J. Seabolt, Schenectady, N. Y. The motor circuit is closed for a predetermined period, and means are provided for disconnecting the motor from the winding mechanism when the motor circuit is opened.

897,020. ELECTRIC CLOCK WINDING MECHANISM. George H. Rupley, Schenectady, N. Y., assignor of one-half to Frank J. Seabolt, Schenectady, N. Y. The clock mechanism is connected with the motor, whether the motor circuit is open or whether the motor circuit is closed.

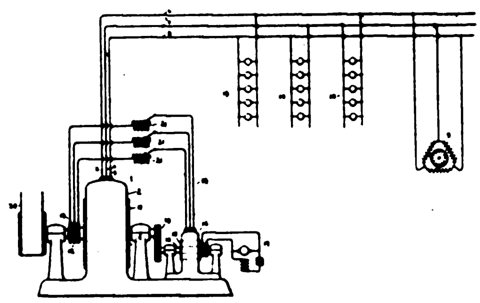
897,024. SYSTEM OF ELECTRIC METERING. Ernest Schattner, Schenectady, N. Y., assignor to General Electric Company. Means are provided for connecting the field coils in series with one or another set of translating devices.

897,028. CIRCUIT SYSTEM FOR TELEPHONE REPEATING APPARATUS. Herbert E. Shreeve, Newton, Mass., assignor to American Telephone and Telegraph Company. A combination of reinforcing circuit with an input coil.

897,031. SYSTEM OF CONTROL. Emmett W. Stull, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. The magnet opens the switch to break the motor circuit, the magnet being energized only when the controller is moved backward to its first operative position.

897,039. PROCESS FOR PURIFYING AND FILTERING WATER. Alfred Vogelsang, Dresden, Germany. The material to be purified has small quantities of ozone added to it.

897,042. TELEPHONE SYSTEM. Alfred H. Weiss, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. A central-energy visual-signal telephone system.



897,018.—METHOD OF GENERATING AND DISTRIBUTING ALTERNATING CURRENTS.

897,062. CABLE TERMINAL. Frank B. Cook, Chicago, Ill. A can-top terminal with means for facilitating the holding of the cover piece in place during examination.

897,084. APPLIANCE FOR USE WITH TELEPHONE TRANSMITTERS. Orrin H. Goodrich, Castleton Corners, N. Y., assignor to Edward F. Hutton, New York, N. Y. A cabinet for enclosing a telephone transmitter.

897,085. SPRING JACK FOR TELEPHONE SWITCHBOARDS. Georg Grabe, Wilmersdorf, Germany, assignor to Siemens & Halske Aktiengesellschaft, Berlin, Germany. The spring jacks are mounted on very small spacing centres.

897,110. ELECTRIC INCANDESCENT LAMP. Hans Kuzel, Baden, near Vienna, and Richard Hoke, Vienna, Austria-Hungary; said Hoke assignor to said Kuzel. A plurality of horseshoe-shaped metal filaments is supported by insulating holding devices and connected to supply wires.

897,119. TELEPHONE SIGNAL. Charles Mahler, New York, N. Y. Each branch telephone is equipped with a bell of individual tone.

897,138. SIGNAL SYSTEM. Robert Pfeil, Grunewald, Berlin, Germany, assignor to Siemens & Halske, A. G., Berlin, Germany. The setting lever has normal, intermediate and full-controlling positions.

897,147. ELECTRIC REGULATOR. Thomas M. Pusey, Kennett Square, Pa. The combination of an insulating liquid and a conducting liquid lighter than the insulating liquid resting thereupon.

897,149. BRAKE SETTER. William A. Rideout, Sr., Oshkosh, Wis. The signal is provided with a movable contact adapted to be engaged by contacts on the car.

897,166. ELECTRIC MOTOR. Wilfred Shurtleff, Moline, Ill. The groups of three poles comprising the field magnets have two small poles flanking the larger central pole.

897,186. ELECTRIC WATER HEATER. Joseph R. Ayotte, Montreal, Quebec, Canada, assignor to Jean Baptiste Albert Martin, Montreal, Canada. The heating element is contained in a metal receptacle.

897,194. LAMP-SHADE HOLDER. John Cruikshank, Shamokin, Pa. The relatively movable conical plates are provided with a plurality of gripping members interposed between the plates.

897,203. ELECTRIC FURNACE. Johannes Härdén, London, England, assignor to the Gröndal Kjellin Company, Limited, London, England. A primary coil is positioned on an iron frame in inductive relation to an annular fusion chamber.

897,211. PROTECTIVE DEVICE FOR ELECTRICAL SYSTEMS. Karl Kuhlmann, Berlin, Pankow, Germany, assignor to General Electric Company. The conductors of a polyphase electrical system are provided with a resistance and safety device connecting each conductor with each other conductor of the system, and a low reactance path to ground from the junction of each safety device and its corresponding resistance.

897,212. LIGHTNING ARRESTER. Karl Kuhlmann, Berlin, Pankow, Germany, assignor to General Electric Company. A multi-gap, variable-resistance arrester.

897,215. ELECTROMAGNETIC SWITCH. William MacMillan, New York, N. Y. The switch is automatically locked or unlocked by means in the controlling circuit.

897,226. MEANS FOR GENERATING AND DISTRIBUTING ALTERNATING CURRENTS. Edward B. Raymond, Schenectady, N. Y., assignor to General Electric Company. The alternating-current generator has two relatively movable members, each provided with a multiphase winding. A resistance in the circuit of the exciter is used for varying the compounding action of the generator.

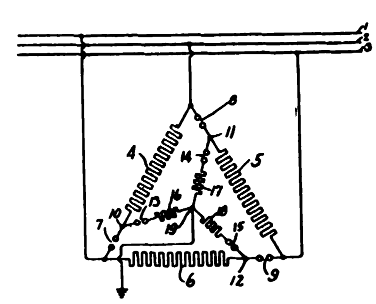
897,232. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. Means are provided at the subscriber's station to control the flow of current in the line.

897,233. TELEPHONE-EXCHANGE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. The signal is displayed when the line circuit is closed at the substation.

897,234. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. Means are provided at the subscriber's station to determine the current flowing in the line.

897,235. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. The signal-receiving electromagnet associated with the line has an energizing winding of low energizing capacity normally in circuit.

897,236. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. A switch is provided at the substation for controlling the flow of current over the line through the substation.



897,211.—PROTECTIVE DEVICE FOR ELECTRICAL SYSTEMS.

897,237. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. A central station provided with a link circuit.

897,238. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. The system is provided with a repeating coil for inductively uniting the line to the terminal.

897,239. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. The polarized repeating coil relay has windings inductively uniting the line to the terminal.

897,240. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. The repeating coil relay is controlled solely by the subscriber, having windings inductively uniting the line to the terminal.

897,241. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. The talking circuit is substantially devoid of resistance and impedance.

897,242. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. Means are provided for interrupting the normal connection during the connection of the ringing source.

897,243. TELEPHONE SYSTEM. Harry G. Webster, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. Current sources of different potentials are used.

897,257. DYNAMOELECTRIC MACHINE. Max R. Hanna, Schenectady, N. Y., assignor to General Electric Company. The machine has two armature windings provided with commutators and adapted to be connected relatively in the supply and load circuits.

CONTENTS

MOTOR LOADS IN HOTELS.

To the central station which numbers one or more modern hotels among its customers the chance for the development of power business is worth following closely, for there is no field where the advantages of the electric motor are more conspicuous. The great problem in operating a hotel is to keep the labor cost down, since in many houses there are often from one to one and a half employés per guest. The wages of many hotel attendants are small, but rarely anywhere near enough to be more economical than a machine capable of doing the same work. The organization of the larger city hotels has been carried to a point of great refinement, but it is a question if the size of the staff can not be very materially reduced by the installation of motor-driven machinery to a wider extent than has generally been the case in the past.

Upon the cleanliness and speed of the service the patronage of a first-class hotel largely depends. Labor-saving devices are therefore at a premium in the management of the most progressive hostelries. In the kitchen and laundry the electric motor affords the cleanest of all powers. It economizes floor space, enables the best lighting conditions to be enjoyed in the culinary department, allows the location of any machine at the most convenient point, and thus facilitates the quickest handling of both raw materials and cooked-food products. It is a great convenience to be able to put a motor-operated machine well out of the reach of the ranges, ovens, broilers, cold-storage chests and other equipment frequently visited by employés, and here the motor drive contributes directly to the acceleration of the service to and from the dining rooms. The severity of the surrounding conditions causes little embarrassment in a motor installation, and the time spent in repairs by the generally overworked maintenance staff of a modern hotel is seldom chargeable in any considerable proportion to the electric motor.

The number of individual applications of motors that can be made to advantage in a large hotel with resources enough to purchase the most efficient labor-saving equipment is too great to specify in a simple list, but in almost every department the convenience of the motor drive justifies its adoption. Passenger and freight elevators, semiautomatic hoists and dumbwaiters, dish conveyers, ash hoists and coal lifts form a class of equipment by itself especially adapted to motor driving. A strong point in favor of the electric elevator is the fact that it takes power only in proportion to the load, while the hydraulic machine consumes practically full power regardless of the weight in the car. The choice between electric and hydraulic elevators is, however, a problem in itself, but for the smaller hoists there is no other power as advantageous as electricity, both in respect of the speed of service and economy of operation. The electrically driven dumbwaiter has reached an advanced stage of development in the later hotel work, especially in its automatic features.

In the electrical operation of bread-mixing machinery, apple parers, bread-moulding machines, ice-cream freezers, fruit cleaners, pie trimmers, coffee grinders, meat and food choppers. silver polishers, knife grinders, cutlery brighteners, pitcher and silver buffers and scrapers, ice crushers, dish-washing machines and other smaller apparatus, there is an excellent chance to save labor through the use of the electric motor. Over steam the efficiency is undisputed, but the chief gain to the hotel management is, as indicated above, in the cost of attendance. When a single chopper driven by an one-horse-power motor will handle from 500 to 750 pounds of meat in an hour; when a two-horse-power washer will clean 3,000 dishes in sixty minutes, and a knife polisher brighten 250 knives in half an hour, the possible savings in hand labor become attractive. The cost of the machine is a small matter when its capital charges and operating expenses are balanced against the wages item with and without the machine under the conditions usually prevailing in hotel service. In the field of general motor application, driving small fans, pumps, refrigerating apparatus, and notably in keeping the odors of the kitchen away from the cafés, corridors, etc., in assisting fireplace ventilation, or in extracting smoky air from the banquet rooms, in operating sewing machines in the linen division, and in numerous other uses, the electric drive can be made so serviceable that the central station man who fails to emphasize these features in seeking to enlarge his power load in the hotel field lets slip an excellent opportunity to secure business of the most desirable kind.

THE RELATIVE HYGIENIC VALUES OF ELECTRIC INCANDESCENT LAMPS AND GAS.

Among the advantages claimed by the electric lighting companies for the incandescent lamp as compared with gas are its higher luminous efficiency and the fact that it does not give off useless, if not objectionable, gases. It is contended, and apparently with good reason, that since the incandescent lamp gives off only about half as much heat as an equivalent incandescent gas lamp, the latter will heat the air in a room to a higher temperature, which is a disadvantage when it is desired to keep the room cool, and since the gas lamp depends upon the combustion of gas for producing incandescence, and this combustion uses up oxygen, while there is no combustion in the incandescent lamp and no utilization of oxygen, the latter source of light should leave the air of a room in better condition for use by those persons therein. Theoretically, no fault can be found in these arguments, so that it only remains to demonstrate how far they apply to actual conditions. If living rooms were airtight there would be no doubt of what actual tests would show; but fortunately for the health of the race all buildings are more or less pervious to air, so that a certain amount of ventilation takes place without any special provision having been made for it. The air in a room is constantly changing at a rate depending upon many factors—the number of windows and doors, the character of the walls and ceiling, the state of the weather, and the location of the room with respect to other parts of the building, or to other buildings. In buildings of light structure the ventilation will generally take care of itself unless there be an unusual number of persons in a room at a time. But in the heavier buildings, such as are constructed of steel and brick, or stone, and which are usually heated by steam or hot water, ventilation must be provided. It, therefore, becomes an interesting question as to the effect of the source of light upon the air of a room and the additional ventilation necessitated by it.

Until about a year ago no figures obtained from actual tests had been published. Last summer, however, Mr. Vivian B. Lewes, in a lecture before the Royal Naval College, of Greenwich, England, touched upon this point and made the statement that the very features of the gas lamp which the electrician considered as faults were benefits, since the greater amount of heat set free, as compared with the incandescent electric lamp, and the volume of hot gases produced acted as ventilating agents and kept the air of the room purer and in a better condition for the use of the occupants. Mr. Lewes's contention, however, was spoiled by the manner of presentation, which was too obviously that of one determined at all hazards to show that gas was in every respect superior to electricity. Hence little weight was given to his statements and in the instances in which the electrical journals noticed them they were ridiculed.

More recently the question has been investigated somewhat carefully by Dr. Samuel Rideal, a recognized authority in sanitary matters in England. His results were presented to the Royal Sanitary Institute, and are given in abstract in the *Engineering News* for July 30. The investigation was carried out on three lines: into the direct effect of the light; into the effect of the products of combustion, respiration, perspiration, etc., and into the nature, amount and distribution of these products. A lack of information on the ventilation of rooms and the results of physiological examinations of persons while at their normal tasks made the investigation more troublesome than had been anticipated. About fifteen persons took part in the experiments, all normal individuals.

The experiments were carried out in a basement room of a London office building. This room had been formed by throwing two rooms, each fourteen feet by sixteen feet, into one. It had one front wall containing four windows. Later this room was cut into two similar rooms, each with two windows, by means of a wooden partition and screens. To minimize disturbances due to persons entering the rooms, air locks were constructed out of baize doors placed in the corridors at the entrance of each room. The rooms were cleaned and whitened before beginning the tests, and the ventilation was brought partially under control by means of an adjustable grating. From the results of the tests, however, there seems to have been ample ventilation due to leakage around doors, windows, etc. At first the rooms were unheated, but when the weather turned cooler electric heaters were put in, this type being selected to avoid, as far as possible, bringing in any other agent which would affect the air in the rooms.

Before dividing the large room into two the gas and the electric lamps were used on alternate evenings. Afterward gas was used in one room while the electric lamps were used in the other, the two systems being used alternately so as to avoid any change which might result from the continuous use of one system in one room. Each room was fitted with a central fixture containing two electric and two gas lamps. Both types of lamp were rated at twenty-five candle-power, the gas lamps being of the inverted-mantle type taking 1.28 cubic feet of gas an hour, and the electric lamps consuming ninety-four watts each. The arrangements of the two types gave a more intense illumination on the table beneath the lamps, where the experimenters worked, when the gas lamps were in use, but a better general illumination when the electric lamps were employed. To these differences were attributed the slight difference in the optical effects noticed during the experiments. The heat liberated in an hour by the gas lamps was computed, from the calorific value of the gas, to be 1,382 British thermal units; that liberated by the electric lamps was something less than half this, being 658 British thermal units.

At first the ventilation was watched by determining the quality of the air before and after each evening's work, but the changes found were so slight and so variable that no satisfactory conclusions could be drawn. Then the plan of introducing a large quantity of carbon dioxide was resorted to. This was thoroughly mixed with the air of the rooms, and the rate at which the air returned to normal was taken as a measure of the ventilation. This method showed apparently that there was a slightly better ventilation when the lighting was done by gas than by electricity, a result attributed to the greater amount of heat produced and the hot products of combustion. But it was found that the heat given off by the occupants of the room and their movements had much more to do with the ventilation than either of the systems of illumination. Nor did changes in outside conditions, except the temperature, seem to have any effect; if anything the ventilation was somewhat better with a moderate wind blowing, or when the weather was fairly quiet, than when a strong wind prevailed. The only influence noticed was the difference in temperature between the air in the room and that outside; the greater this difference the more rapidly was the air of the room changed. This result is rather remarkable because the tests were carried out in a building with massive walls and the ventilation was restricted, and, moreover, it was computed that about twenty-eight per cent of all the heat developed in the room was carried away by the air, the remaining seventy-two per cent being carried off by radiation and conduction through the walls.

Other tests were made to study the effects of other influences: the humidity of the air was varied from very dry to very moist without appreciable effect on the occupants; the organic matter exhaled by those in the room was collected in potassium permanganate and it was found that less was collected in this way when gas was used for lighting, the burning gas evidently destroying a certain amount of these volatile substances; the traces of sulphur dioxide formed by the burning coal gas seemed to have a germicidal action on the bacteria existing in the room; coal gas was allowed to escape into one room at the rate of 8.8 cubic feet an hour for over four hours, but no serious symptoms were noticed in any of the three men who remained in it.

The *Engineering News*, in an editorial commenting upon this work, says it remains to be seen how those interested in electric lighting will receive this blunting of one of their favorite weapons of attack, and then proceeds to show that the blunting is not as serious as at first seems. The tests were made in cold weather, which, it is evident from the tests, is more favorable to gas. Similar tests during the summer might show different results.

It is to be noted that the differences found between the two systems of lighting were slight and neither one was as important a factor in determining the conditions in the room as the occupants themselves. Such conditions are not favorable to accurate differentiation between the effects of the two lighting systems. The tests were conducted in a steel-framed structure which dissipated seventy-two per cent of the heat by conduction and radiation and the results are not applicable to buildings of other types. Moreover, the two systems of illumination were used alternately so as to avoid differences resulting from the use of the two rooms without change. If the object of the investigation was to detect differences between the two systems of illumination it would seem logical not to alternate in this way and to let the differences accumulate. It is not customary to vary one's system of lighting as was done here. Another point to be remembered is that the tests were conducted with incandescent gas lamps and the results do not apply to open burners.

Dr. Rideal's results are interesting, but not entirely convincing, and further tests will have to be made before it can be said that the superiority of gas has been demonstrated. It would be well if some of those interested in electric lighting should undertake similar investigations under somewhat different conditions. We should be much surprised if some of these tests, should they be made, do not show quite different results. As we remarked before, the electrical advocates' theory is sound and it only remains to show how far it applies in practice.

DANGEROUS HAND LAMPS.

A recent report, prepared by Mr. G. S. Ram, inspector of factories for the British Board of Trade, calls attention particularly to what seems at first a slight defect in electrical hand lamps, but which the inspector says has already caused three fatal accidents. These are electrical hand lamps attached to a flexible cord, with a wire guard for protecting the bulb. The guard is very frequently attached to a metal base, clamped upon the lamp sockets. The cord itself is usually, for convenience, passed through a hole running through the insulated handle. The trouble with this device is that occasionally the metal plate supporting the guard becomes alive, due to some injury to the insulation of the wire. The guard is, of course, in metallic connection with the socket, and is alive whenever the latter is. And, although the user of the lamp would avoid touching the socket, he is not apt to anticipate danger in touching the guard. Sometimes, indeed, the socket is attached to a brass ferrule, which seems to form part of the handle, and which the uninitiated would not consider part of the socket, although it is metallically connected thereto. It was just these faults which gave rise to the three deaths referred to above.

This defective construction should never be allowed because of the risk when such a device is used on alternating currents. The fault is easily corrected by supporting the wire guard on an insulating plate or shell, thus avoiding any metallic connection whatever in the pocket. There are a number of such arrangements available, one of which should always be adopted. The reason is so apparent it would hardly seem necessary to call attention to it, if the defective arrangement had not actually been the cause of death. It may be added that it is just as important to avoid an arrangement which is likely to bring the hand of the user of the lamp in contact with the connecting wire, when the arrangement of the handle is liable to injure the insulation of the wire. We are apt to forget that even though the actual potential at the lamp is low, it is possible by a combination of defects for a high potential to exist between the lamp and the ground if the system of distribution employ alternating currents.

ILLUMINATION AND OUR EYESIGHT.

In an interesting editorial discussion our London contemporary, *Engineering*, takes up the possible effect upon our eyesight of the brilliant illumination which is now so much in popular favor. The introduction of powerful electric incandescent lamps, fitted with metallic filaments, has increased the complaints from those who see in the intense brilliancy of the newer forms of lamp a lurking danger. It is conceded that with the improvement in our newer forms of incandescent lamps we have been receiving more and more ultra-violet rays. In many cases where the light source is surrounded by glassware more or less opaque to the ultra-violet rays, this effect has been masked, and has lessened what, in some quarters, is considered a danger. It is well known, however, that experimenters working with metallic filaments at a point of high incandescence have been affected by severe irritation of the eye and eyelids, and this effect has been set down to the prevalence and activity of the ultra-violet rays. Coincidentally, the effect has been noticed where the filaments have been encased in quartz glass tubes, the quartz glass being, of course, more transparent to the ultra-violet rays than is the glass from which the ordinary lamp bulbs are made. Both the crystal lens and the retina of the eye are said to be affected by ultra-violet rays, and it is also announced that a good many of our protective spectacles are of little value. Dr. Fr. Schanz and Dr. C. Stockhausen regard the ultra-violet rays as a source of danger, and point to the experience of several operators as conclusive testimony to this effect. On the other hand, Dr. Voege, of the physical government laboratory, of Hamburg, after conducting numerous photographic experiments to determine the abundance of the ultra-violet rays in our modern illuminants, as compared with sunlight, states that the danger is exaggerated. The chief results of Dr. Voege's experiments would seem to indicate that the ultra-violet rays are more plentiful in the sunlight than they are in various forms of incandescent illuminants, with a few exceptions. His experiments, however, are all photographic, and the eye certainly, as far as we can determine, is not sensitive in the same order as is the sensitized plate.

Direct photographs of the spectra of various lamps and of the sunlight taken through the slit of a spectrograph gave a much longer ultra-violet spectrum in the case of sunlight than any lamp, and the interposition of a screen of window glass did not much alter the result. Even the sunlight reflected from the slabs of sandstone stairway was richer in ultra-violet light than the electric light. Dr. Voege concludes that the eye receives less ultra-violet light from the lamps than from the direct sunlight, but makes suggestions concerning the shielding of the eyes from the direct light of the former.

What the real danger is still remains to be discovered. Fortunately, we are not inclined to gaze directly upon the glowing filament, and in most modern illumination good taste demands that the direct light from the filament be diffused by means of some form of semi-opaque glassware. The experiments which have been announced by the workers just mentioned, and their results, will be watched for with keen interest by every one having to do with the subject of illumination.

The whole subject of the effect, whether for good or evil, of the invisible radiation, is worthy of continued study. The early practitioners with the X-ray found to their cost that careless handling caused disastrous results both to the operators and to the patients subjected to the photographic influences of the Roentgen ray. Nowadays the danger has been eliminated, due to the scientific use of filtering screens and the shortening of the time necessary for a complete and satisfactory exposure. There are also many well-authenticated cases of burns from the invisible radiation from radium emanations, and the penetrating power of these rays, too, was discovered accidentally. These accidents and such work as is being conducted by Drs. Schanz, Stockhausen and Voege indicate that wherever the invisible radiation is involved, or where there is good reason to suspect that it is present, care should be taken to guard against damage in so far as our present methods of protection will insure possible safeguards.

In still another direction comment is raised, and a warning is sounded that the etheric impulses propagated through the use of wireless telegraph systems will have a deleterious effect upon living organisms. Of course a good deal of this will doubtless prove to be visionary, but that certain effects are produced upon certain forms of anatomy appears to be assuredly a fact. It is to be hoped that further investigation will make us so familiar with cause and effect that we can detect, arrest and utilize to the service of man these elusive and at present hidden forces.

CORROSION OF IRON FROM THE ELECTROCHEMICAL STANDPOINT.[1]—I.

BY C. F. BURGESS.

Depreciation is a subject which is to-day occupying the attention of financiers, economists and accountants. It is one which presents various phases, none of which is more important than those of obsolescence and physical decay. For one of these the engineer may be held responsible; the other he should work to prevent. Obsolescence comes as a direct result of new discoveries in science and their adaptation to man's use. Physical decay apparently follows the working out of nature's process, yet it has been proved possible for the scientist and engineer largely to reduce the rapidity with which such decay progresses.

In the use of iron as the most important structural material, attention has been given hitherto more to design and erection than to preservation, but as the amount of erected iron increases, the importance of preserving it likewise increases. The older our existing iron structures become, the greater is the need of retarding their decay.

The phenomenon of physical decay of iron and its alloys has long been known, but is little understood. To control it a deeper knowledge of the underlying causes is necessary. When we recognize the fact that iron structures depreciate annually in value through physical decay at a rate varying from perhaps one per cent to twenty or more per cent we have a means of stating the importance of this in money units. When viewed from the standpoint of safety to life, as well as that of preservation of property, the matter takes on a far greater significance.

The importance of this subject from economic, socialistic, governmental and humanitarian standpoints should be sufficient to enlist interest in the work, quite aside from the fascination which it exerts in itself. As Sir Robert Austen has said, "The study of metals possesses an irresistible charm for us quite apart from its vast national importance. Metals have been sadly misunderstood; in the belief that animate beings are more interesting experimenters have neglected metals, while no form of matter in which life can be recognized is thought to be too humble to receive encouragement. Bacteria with repulsive attributes and criminal instincts are petted and watched with solicitude and comprehensive schemes are worked out for their development and culture."

Corrosion of iron may be considered as the generic term covering a number of diseases peculiar to iron and iron alloys. So little is understood as to the causes of even the most common of these diseases that to prescribe for them requires considerable assurance on the part of the experimenter. There is an insistent demand at the present time for further experimental study of corrosion and for the gathering of accurate records on corrosion phenomena.

Some of our leading authorities hold that primarily iron corrosion is an electrolytic phenomenon. Such a view was advanced by W. R. Whitney (Journal American Chemical Society, 1903, page 394) and this was corroborated and notably extended by W. H. Walker (Journal American Chemical Society, 1906, page 1251). A. S. Cushman, through some interesting experiments described to our society last year, also sought to ascribe corrosion to electrolytic action.

The acceptance of such a belief would place upon the electrochemist the first responsibility of making a thorough study of iron corrosion, and it is certainly true that such research would offer him a most attractive field for work.

In viewing corrosion of iron as an electrochemical action, it may be desirable to divide into classes various kinds of corrosion encountered in practice. The first class to be considered is:

CORROSION OF UNDERGROUND STRUCTURES.

It is well known that under normal conditions, iron pipes buried in the earth for distribution of gas and water will corrode so slowly that the life may well exceed a century. The owners of such pipes were greatly disturbed not many years ago to find that a disease had been contracted by their pipes, presumably through association with electric railways. They attempted, and are still attempting, to demonstrate to the courts that the railway companies are responsible for damage caused to their pipes by the leakage of currents from the railway returns.

It has been shown beyond doubt that current flowing from iron to earth subjects the iron to electrolytic corrosion, but beyond discovering methods for mitigating the destruction, the electrochemist has not succeeded in freeing from electrolytic trouble pipes located near a single-trolley railway.

This phenomenon has attracted such attention that to many people the term "electrolysis" is synonymous with destruction of underground pipes. In spite of extensive study which has been given to this matter it is interesting to note various curious beliefs which are held even by some of the experts. Thus we have the disputed point as to whether current flowing from iron to earth will cause a quantitative corrosion as required by Faraday's laws; some hold that the earth conducts to a certain degree metallically, and therefore a small current density may not cause any corrosion whatever; while others assert, and probably more correctly, that Faraday's laws hold exactly for large and small currents alike. Testimony has been given to the effect that the flow of current through the earth results in the deposition of a coat of iron upon pebbles in the earth, a phenomenon certainly of interest to those who have experienced the difficulty of depositing iron under most favorable conditions upon a conducting cathode. The statement is repeatedly made that current flowing from the rails to the pipes does not produce electrolysis, but that current flowing in the reverse direction is dangerous. This, of course, is only another case of "whose bull is gored."

In the study of this type of corrosion the electrochemist is called upon to clear up erroneous beliefs by quantitative measurements. So far remedies applied have been qualitative rather than quantitative, and before accurate work can be done in treating this trouble a large amount of data must be available; such as the specific electrolytic conductivity of various earths, clays, gravels, etc. The minimum electromotive force for flow of current must be more carefully studied to determine whether an electromotive force, no matter how small, will cause electrolysis, or whether polarization is to be counted upon.

Some authorities assert that if the direction of the flow of current can be reversed occasionally the electrolytic corrosion of both electrodes may be prevented, the argument being that current flowing from the iron will carry iron in a solution and that some iron will be redeposited when the direction of the current is reversed. This remedy has been attempted in the operation of certain electric railways by reversal of the polarity of the generators once a day or every hour, or even more frequently, and the observations made during such practice led to the conclusion that the more frequently the reversals are made the less is the danger from electrolysis. In fact, when we carry this practice to its extreme

[1] From the presidential address before the American Electrochemical Society, Albany, N. Y., April 30.

limit and have a reversal several times a second we arrive at alternating-current transmission, the advent of which is generally assumed will be an absolute cure of electrolytic troubles, although some experts assert that an alternating-current system of distribution will not remedy present difficulties. The writer's experience in depositing iron from a solution even under the most favorable laboratory conditions has led him to believe that the chance conditions to be met with in the earth are not unlikely to make it possible to deposit iron from the earth on to the metallic electrode. Consequently relief from an occasional reversal of the current does not appear practical of attainment. This statement may not apply, perhaps, when the frequency of reversals is so rapid as to make the current come under the classification of alternating current.

GALVANIC ACTION.

Iron in contact with a metallically conductive material electronegative to itself, and both making contact with an electrolyte, constitute an active electrochemical system in which the iron is subject to corrosion. The rate of corrosion depends upon the electromotive force, upon the conductivity of the electrolytic and metallic conductors, and upon the polarization. If the electrolyte is such that the hydrogen is liberated on the electronegative surface it may produce polarization sufficient to stop the flow of current. If a depolarizing material be present the polarization will be decreased and the increased current thereby produced results in increased rate of corrosion. (Walker *et al*—Journal American Chemical Society, 1906, page 1251.)

As examples of an electrochemical system of this type, the following well-known cases may be named: An iron ship in a harbor with a copper-sheathed ship are considered undesirable companions, since if metallic contact be made between the two, the iron suffers by being made the anode of a huge electrochemical system of which the copper ship is the cathode and the sea water the electrolyte. It is not good practice to attach a bronze propeller on a steel shaft of sea-going ships, for unless suitable protective steps are taken the neighboring steel will be damaged.

The more electronegative the material the more marked is the electrolytic action, and some forms of conductive carbon have properties such as to make the electrolytic action particularly pronounced. Various investigators have pointed out that carbon cinder embedded in an iron surface, or carbon making contact with iron in any way, engenders corrosion by galvanic action. This action takes place whether the piece of iron is of large or small size, and the kind of action produced by particles of microscopic size is identical with that produced by the large particles. The uncombined carbon which chemical analysis shows to exist in certain kinds of iron may therefore increase the corrodibility of such iron. The measurement of the single potential of iron sulphide shows this to be electronegative to iron and its presence in iron will give rise to active couples. It can hardly be doubted that such surface exposing spots of iron sulphide is one upon which electrolytic action will take place if an electrolyte be present.

Almost any microphotograph of iron and its alloys shows non-uniformity of composition of surface exposed to corrosion, and we are justified in the belief that the micrographic constituents should be studied in dealing with iron corrosion from the electrochemical standpoint. We do not know in what electrochemical order the ferrite, pearlite, cementite and other constituents of iron alloys may arrange themselves. Data as to the single potential of these various constituents are needed if we would express quantitatively the tendency of a certain combination to corrosion. At the present time our only knowledge of these potentials is of a qualitative kind and also very fragmentary. The available published data come from the records of the work done by the metallographists in their microscopic study of iron. Highly polished iron surfaces have been treated with various corroding acids and reagents, the purpose being to corrode the different constituents at different rates under the microscope. A study of the literature on metallography for the purpose of classifying these observations might constitute interesting and valuable work.

It is perhaps doubtful if the exact measurement of any one constituent could be made, at least with the present method of measurement, since in measuring the electrical potential of an iron or iron alloy, a value is obtained which may be the electromotive force given by the most positive constituent, or it may be that produced by the polarization phenomenon, or it may be some intermediate or composite value. W. H. Walker and associates (Journal American Chemical Society, September, 1907) have devised an ingenious method for determining the different potentials established by different portions of an iron surface, and they have shown "that in certain instances areas having marked difference in potential exist in far greater number upon the surface of a piece of iron prone to corrosion than upon iron which is resistant to corrosion." Whether this method would lend itself to the measurement of microscopic portions of an iron surface is problematical. An active electrochemical system can usually be detected wherever corrosion is observed, but whether corrosion can exist where no electrolytic action is possible is a matter which appears far more difficult to determine.

Assuming a similarity in chemical composition and metallographic constitution in different samples of iron or iron alloys the question may be asked, "Can the single potential differ in different specimens or different parts of the same specimens?"

INFLUENCE OF STRAIN ON CORRODIBILITY.

Does strain in iron increase tendency to corrosion? This is a question which has been the subject of interesting discussion and upon which there is radical difference of opinion. Data obtained by different investigators are quite contrary, and it is natural then that contradictory conclusions have been drawn.

In referring to those radically different conclusions of different experimenters the writer disavows any desire to enter into a controversy. But it appears that unless errors which are allowed to creep into methods of measurement are recognized and then guarded against, the data obtained can be of little value and these errors can perhaps be detected by comparison of the methods employed by different observers.

As a matter of scientific interest we may refer to that well-known riddle which runs as follows: Two steel clock springs are identical as to weight and quality of material, and differ only in that one of the springs is coiled and the other uncoiled. These are immersed in an acid solution and completely dissolved. What has become of the energy which was stored up in the coiled spring? The answer which most easily suggests itself is that this energy must have been liberated during the chemical process of solution and manifested itself as heat. Upon this supposition in dissolving the coiled spring more heat would be liberated than in dissolving the uncoiled spring. Further, the coiled spring would be more chemically active, and if so this chemical activity should be manifest as increased electrical contact potential existing between the metal and the solvent.

There are many instances coming under practical observation which seem to bear out the idea that a metal under strain is more subject to a dissolving or corroding action than is unstrained metal, this relation being particularly true in iron and its alloys. Mr. James Andrews in 1894 (Proceedings of the Institution of Civil Engineers) described some experiments by which he attempted to demonstrate that strained iron has a higher potential in a corroding solution than has unstrained. He concluded, however, from the results of his measurements, that the reverse condition holds, and that unstrained metal is more rapidly acted upon by the solution than the strained metal. Mr. Carl Hambuechen in 1900 (Bulletin of the University of Wisconsin, Engineers' Series) pursued an investigation which was, in a measure, a duplicate of that made by Mr. Andrews, with the exception that Hambuechen sought to eliminate some error in the former work by modifications and refinements in the method of measurement. He produced experimental data showing that the iron behaved as it should according to theory, and in fact he was able to secure, in some cases, a remarkable similarity of stress-electromotive-force diagrams with the stress-strain diagrams obtained simultaneously on the same sample. He says, "The application of stress to metal causes an increase in chemical activity, this increase being especially marked after the elastic limit has been reached."

In 1906 T. W. Richards and G. E. Behr, Jr., contributed a paper to the Carnegie Institution of Washington, publication No. 61, entitled "The Electromotive Force of Iron Under Varying Conditions and the Effect of Occluded Hydrogen." This paper asserts the presence of regrettable errors in Hambuechen's work, and among the conclusions it is stated that "measurements of the free-energy change in iron during a pull upon wire great enough to cause rupture gave results showing that this change must be very small." The authors apparently conclude from their work that the changes in electromotive force actually produced are too small and the data too scanty and irregular to warrant conclusions of value being drawn. This view apparently places Hambuechen's data under the charge of accidentally falling into a systematic order, which order would not have been shown had the alleged errors been avoided.

In 1907 Messrs. W. H. Walker and Colby Dill discussed "The Effect of Stress Upon the Electromotive Force of Soft Iron" before the American Electrochemical Society. In their summary the statement is made that "the magnitude of the potential suffered by soft iron when tested in a tension machine below the elastic limit is exceedingly small. . . . The change, when great enough to be measured, was negative; the strained metal had a slightly lower potential than the same metal unstrained. . . . . . Somewhere above the elastic limit the potential rises suddenly several hundredths of a volt."

It may perhaps be not unprofitable to enter into a consideration of the cause of the marked differences of the results obtained by different observers and the diametrically opposite conclusions which were drawn therefrom. Of the various authorities mentioned, Hambuechen has apparently secured results which uphold that plausible theory that iron upon which mechanical work has been done retains some of the energy in a potentialized form capable of being measured by electromotive-force readings. The other authorities discredit these results. It is probable that none of the results referred to have been obtained under conditions which are free from all sources of error. Hambuechen's work was done under the supervision of the writer, who therefore feels justified in discussing some criticism of his methods and conclusions. Mr. Hambuechen pointed out in his bulletin that chances for error existed in Andrews's work by reason of the fact that the surfaces whose potential was being measured were not protected from action of the air. He devised a cup-shaped arrangement which surrounded the sample of iron in the testing machine and carefully protected all of the parts of the iron from the air and the electrolyte except such portion of the surface as was kept immersed in the electrolyte and whose potential was being measured. He recognized that the amount of potential changes was exceedingly small and that the potential established by a metal in contact with an electrolyte is easily upset by the flow of exceedingly small amounts of current. The use of an ordinary galvanometer used in connection with the compensation method was believed to allow the flow of sufficient current to materially polarize the small surface under measurement. He therefore used a capillary electrometer, which acts as a condenser of small capacity and does not allow the steady flow of current through it. This electrometer had a sensitiveness of 0.0007 of a volt, and in addition to this sensitiveness it was unaffected by vibration and magnetic disturbances and could be mounted in close proximity to the testing machine.

Messrs. Richards and Behr employed a D'Arsonval galvanometer sensitive to 0.001 volt, and they apparently did believe it necessary to guard fully against polarization phenomena. Walker and Dill likewise took this view as to the precautions deemed necessary, for they employed a D'Arsonval galvanometer of fairly high resistance but provided with a shunt "to protect the galvanometer from too heavy currents during the preliminary adjustment of the resistances."

In both papers referred to, that by Richards and Behr and by Walker and Dill, objection is made to Hambuechen's results on account of his use of ferric chloride as the electrolyte against which the potential of the iron was determined. The former writers say that "this unfortunate choice" (of ferric chloride) "completely invalidates all the results. The reason is very simple. Ferric chloride is always hydrolized to a considerable extent —that is, it contains acid. . . . . . There exists in the electrolyte a continually changing concentration of ferric, ferrous and hydrogen ions and reliable work is out of the question. The effect of these influences combined would cause the electromotive force to change steadily, quite independently of any stress and strain effects." Data are given showing that in two cases the electromotive force of iron rose 0.192 and 0.123 volt in about seventeen hours, and they say that this rise would have been ascribed by Hambuechen to strain.

While it is perhaps true that a solution better than ferric chloride might be chosen, the criticism of Hambuechen's work for this reason is perhaps too severe, since he did recognize the fact that the electromotive force was subject to change, regardless of any strain effect. The change becomes so slow after a half-hour that a stress-strain diagram could be run through in a sufficiently short time that the natural change would have little effect in masking the changes produced by strains. In fact, in producing autographic record of the stress-strain diagrams the testing machine was run continuously and the electromotive-force measurements had to be taken with some rapidity. The writer believes that these observations of varying electromotive force are more probably the results of potentialized energy in the iron than the effects of hydrolysis of the ferric chloride solution, as emphasized by Richards and Behr.

The feature which at first sight might discredit more than any other the accuracy of Hambuechen's results is that he found changes in electromotive force which were materially greater than those calculated on the assumption that all of the energy applied to an iron rod in pulling it apart is thereby potentialized.

Barus has studied the disposition of energy applied in rupturing a piece of iron. ("The Energy Potentialized in Permanent Changes of Molecular Configuration," United States Geological Survey Bulletin, No. 94, 1892.) And quoting from him we read: "To summarize, it appears that as much as one-half of the work done in stretching up to the limit of rupture may be stored up permanently. Calculation of the increase of electromotive force by the potentializing of energy in iron involves the application of the formula

$$E = \frac{W \times c}{96540 \times g}$$

where

E is increase of electromotive force in volts.

W is energy stored, expressed in watt-seconds.

c is the chemical equivalent.

g is weight in grammes of the iron in which the energy is stored.

From measurements of stress and deformation Hambuechen calculated that the possible increase in electromotive force on a particular sample was 0.0126 volt (on the erroneous assumption that all of the applied energy was potentialized). He found in some of his measurements values two or three times as high as were apparently theoretically possible, to explain which he assumed an excessive storing of energy in the outer layer of iron as compared with that at the centre. Richards and Behr were justified in considering this an erroneous assumption. They have apparently overlooked the possibility, however, of a non-uniform distribution of such energy as may be potentialized by strain, for in their calculations of electromotive force they have assumed the energy to be equally stored in all particles of the sample of iron.

Ewing and Rosenhain, in a paper on "The Crystalline Structure of Metals" (Philadelphia Transactions, Royal Society, Vol. cxciii), have given results of microscopic study on the effect of strain on metals. It is well established in their work that the influence of strain is not uniformly distributed throughout the mass. It appears that the shape of the grains is altered, but that the crystals making up the grains are not deformed. "The conception that metals adapt themselves to the new shapes imposed upon them when they undergo plastic deformation by means of slips along cleavage or gliding planes within each crystalline grain leads naturally to the supposition that the crystalline elements themselves undergo no deformation in the process."

Energy is expended in overcoming the adherence or attractive force between crystals, and if there is a storage of this energy it might well be considered as being stored in the portion of metal adjacent to these surfaces. As this metal, containing potentialized energy, is exposed to the electrolyte, the electromotive force of this portion will be greater than that of the remaining portions. To calculate this electromotive force according to the formula given requires a knowledge of the actual weight of that portion of the metal in which the energy is stored, which obviously would be less than that obtained by weighing the entire mass. This weight is, of course, impossible to determine by known methods of measurement.

The electromotive force of the most electropositive particles is then greater than the average electromotive force calculated. The question then arises as to which value—the maximum, the minimum or average value, or some value of overvoltage of hydrogen—is obtained by experimental measurement of contact potential. Richards and Behr have described their determination of the single potential of small globules of iron around which were wrapped platinum wires to make contact. Their voltages are given as being the values for iron even though it is in contact with the more electronegative platinum. Likewise we have in a zinc amalgam the electromotive force of the zinc almost unaffected by the electronegative mercury. From analogy we might expect, therefore, that the potential would be that set up by the most electropositive particles on its surface. And if this line of reasoning is correct, we can easily explain why Hambuechen's measured values of electromotive force were higher than those calculated, and we may perhaps wonder why the differences were not even greater than found.

It should be recognized, in comparing the results of different investigators, that the materials designated as iron may, in fact, be different grades of iron. Richards and Behr confined their attention to highly purified iron, while Hambuechen used the term more loosely as designating the commercial grades of the metal. He found that the increase of potential by strain is more marked in steel than in pure iron, and a microphotograph of steel reveals the presence of various constituents. In all probability there is a difference in the storage of energy in the various constituents, and consequently the possibility of higher electromotive forces.

It may be emphasized again, and in this connection, that the microscope is a useful device in studying the phenomena pertaining to the corrodibility of iron.

(To be concluded.)

Semiannual Meeting of the National Association of Cotton Manufacturers.

The semiannual meeting of the National Association of Cotton Manufacturers will be held at Saratoga Springs, N. Y., September 29 and 30. The sessions will be held in the ballroom of the United States Hotel at 10 A. M., 2.30 P. M. and 8.15 P. M. on Tuesday, and at 8.15 P. M. on Wednesday. The fore part of Wednesday will be devoted to an excursion to the works of the General Electric Company at Schenectady, as guests of that company.

A programme has been arranged with fewer papers than usual in order to provide ample time for discussion. Among the papers to be presented are several which will bear directly upon the use of electricity in the textile industry.

The Textile Exhibitors' Association will hold its annual meeting at Saratoga Springs on September 29, and at this meeting officers will be elected for the ensuing year. Plans will also be made for a textile exhibit in the spring of 1909.

The officers of the National Association of Cotton Manufacturers are as follows:

President — Charles T. Plunkett, Adams, Mass.

Vice-presidents—George Otis Draper, Hopedale, Mass.; Franklin W. Hobbs, Boston, Mass.

Secretary and treasurer—C. J. H. Woodbury, Boston, Mass.

Auditor—C. E. Roberts, Boston, Mass.

Directors—Robert Beatty, Philadelphia, Pa.; Frederick A. Flather, Boston, Mass.; George P. Grant, Jr., Fitchburg, Mass.; Edwin Farnham Greene, Boston, Mass.; David S. Johnston, Cohoes, N. Y.; John W. Knowles, New Bedford, Mass.; William H. Loftus, Newark, N. J.; Henry F. Mansfield, Utica, N. Y.; Joseph Merriam, Middletown, Ct.

A Twelvemonth's Achievement of the Tungsten Lamp.

By S. E. Doane, Chief Engineer, National Electric Lamp Association.

THE past twelve months has marked the greatest progress in the history of artificial lighting. No epoch equal to it has ever been known. The advent of the incandescent lamp itself was possibly a greater scientific achievement, but no one period of time since has marked so great a change or benefit to the general public.

The carbon lamp created a field for itself. The tungsten lamp found the field created.

The carbon lamp was put into service with many frailties, whereas the latest unit was given to the world as a product of splendidly equipped laboratories and workshops where the testing and perfecting had all been done. The customer was made to suffer from the mistakes of the manufacturers of the early carbon lamp. This has not been the case with the tungsten. The new lamp from the first has outstripped its guaranteed performance and nowhere has there been a single failure of this lamp to fulfil all expectations.

The Nernst and Gem lamps were perfected several years too late, to have been fully appreciated. It is also a pity that the achievement of the tantalum lamp should have been so quickly superseded by the greater achievement of the tungsten.

The last twelve months have seen general recognition of the fact that the enclosed arc lamp is being superseded for interior lighting, while the Nernst lamp is entering upon this stage of its history.

The carbon lamp is still holding its own in quantity of production. Its rate of increase of production has been materially decreased and at no distant day the replacement of carbon lamps by tungsten will offset the new installations where the carbon lamp should legitimately be used.

It was inevitable that the first shock of the tungsten lamp introduction should occasion much anxiety on the part of the central station managers, but there is now to be noticed the most gratifying optimism on the part of the central stations. Many now report that the tungsten lamp has actually served to increase their revenues. From this time on, it is my belief, that these conditions will continue to prevail.

The central station has seen its worst days so far as decrease of revenue through the tungsten lamp is concerned. It was inevitable that stores and other places of a public or quasi-public character should have been the first to have employed this lamp, due to the fact that the first development of this lamp was in the units of larger candle-power, to which the fixtures in residences were not adapted. Central stations have suffered in revenue where public or quasi-public employment has maintained the volume of light which was sufficient, according to the old standard, with a decrease in current revenue to the station. This condition of replacement was continued for some months, but the progress of the country's recovery from its financial stagnation will now turn the tide.

Although replacement of carbon type lamps with tungsten in such places will continue, nevertheless, the opening of new fields and the general increase in the standard of illumination in such places will offset the decrease in current revenue from the places where illumination is already sufficient and also where the tungsten lamp replaced the carbon.

The next great field for the introduction of the tungsten lamp will be in domestic lighting. Light in public or quasi-public places is a necessity and is regarded as such, but, as with every other necessity, economies of the situation have to be largely considered. The tungsten lamp would have been adopted even at a higher price on account of the improved quality of the light. No up-to-date store can afford to be illuminated by anything else. The quality of light from an arc lamp can be made extremely good, but its flickering character, its comparative clumsiness of installation, its failure to conform well to artistic and architectural requirements, are such that the tungsten lamp has found it an easy competitor.

In the case of domestic lighting, electric light as employed to-day is not a necessity, but is a luxury. The domestic users of electric light are those who are willing to pay something for luxury. The tallow candle and the kerosene lamp are to-day cheaper sources of light, yet the general improvement in the standard of domestic livelihood demands electric light and it is my belief that the advent of this tungsten lamp brings the day of universal electric lighting nearer than any one event in the history of the electric lighting industry. The tungsten lamp is already recognized by the architect and decorator of this country as offering them an opportunity for larger and more artistic color schemes and decoration than have before been possible. Interior decorators with whom I have talked tell me that there is already a noticeable change and that the interiors of public buildings are being tinted to take advantage of the new opportunities. These conditions will likewise shortly prevail in domestic incandescent lighting.

There is another most important consideration in connection with the introduction of tungsten lights in the homes, and this is that the average individual who must divide up his income, living in the best quarters that his income will permit, and undertaking only such amusements as his income will allow, has been obliged to limit his expenditures for light on the same basis. The tungsten lamp will make light cheaper for him as well as giving him a quality of light by which he can better enjoy the furnishings of his home. The effect of this is going to be that the domestic user will use light for longer hours and inasmuch as the tungsten lamp, for the same illumination, will take much less current, the result is going to be that the peak load due to domestic lighting will be greatly changed. It is fair to call attention to this under the subject given me for this article inasmuch as the twelve months passed have already marked the beginning of this change. Residences will be more generally illuminated and instead of lamps being installed with many switches for the sake of economy in operation, the contractors will, in the future, arrange for rooms more generally and continuously lighted throughout the period between twilight and bedtime. This will result in increasing the demand factor and also the load-factor for our central stations with a result that they will be able to decrease rates, which, in itself, will again stimulate the introduction of the tungsten lamp.

Many practical problems have been met and solved in the last year. We now no longer hear of the great fragility of the tungsten lamp. Much of this has been due to increased knowledge in the laboratories by which the filaments have been made stronger. At the same time, the customer himself has learned how to handle this lamp. Breakage in shipment to-day is less than one-half of one per cent. While it is to be regretted that the lamp is as fragile as it is, a general recognition of this fragility, together with an improvement in the strength of filaments, has almost removed the question of breakage from a consideration of adoption of this lamp. Scarcely twelve months ago there was not a single well-equipped, well-established tungsten lamp factory in the United States; to-day there are several with a combined capacity of 75,000 lamps a day, and at present a combined daily output of 25,000 lamps. Prompt deliveries are being made by all tungsten manufacturers.

The next twelve months will see a rapid introduction of train-lighting lamps and other battery users for this lamp. The maker of the storage battery has begun to profit much from the demand for tungsten lamps of low voltage at various candle-powers.

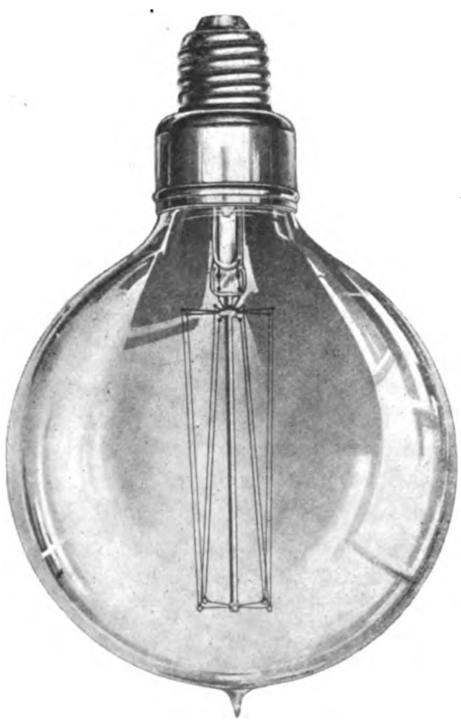
Great as has been the progress in the manufacture and production of this lamp in the past twelve months, an even greater progress awaits it in the twelve months to come. The industry is to be congratulated that the shock of the first introduction of this lamp has been so well met.

There will be other progress in the future. The problem of selective radiation, which the tungsten lamp has so well opened up, will be solved to a greater or less extent in the near future and a comprehensive and serious effort on a considerable scale has been inaugurated for the thorough scientific study of this and other problems underlying our industry. We look for much progress from such work.

Tungsten Lamp Economy.

By Francis W. Willcox.

RARELY does the evolution of an art culminate in such a simple device as the incandescent lamp, and in the case of the tungsten lamp the future appears to hold no prospect of undermining its supremacy as a lighting unit, but on the contrary promises to make its position stronger by increased efficiency.



Sixty-Watt Meridian Tungsten Lamp.

The arguments in favor of the electric incandescent lamp have long made it the standard to which all other illuminants have aspired, but the question of cost enabled its competitors to maintain a strong position in the field. The tungsten lamp distances in average efficiency its strongest competitor, gas, and, ideal in every other respect, places the best illuminant within the reach of all.

MANUFACTURING FACILITIES.

During the year that American-made tungstens have been on the market appreciation of their qualities has been shown by an enormous increase in their sales. Anticipating the demand, the manufacturers have kept pace with their orders after the first few months, and in the immediate future 75,000 per day will be the capacity of American factories, one manufacturer alone advertising facilities for nearly half this number. The economy, brilliancy and general satisfaction given by the tungsten lamp make every one of them a salesman, and the 1,000,000 American-made lamps now giving satisfactory service are dominating factors in the demand for their increased adoption.

RECENT IMPROVEMENTS.

Improvements in the tungsten lamp have been numerous during the year. Specially designed packing cases have reduced breakage in shipment to an almost negligible quantity—out of 100,000 lamps shipped by the company with which the writer is connected less than one and one-half per cent were lost, and damage from careless handling has naturally been eliminated by a realization of the caution required in installing. While the pendent position is recommended, tungsten lamps as now made give excellent results when burned at any angle.

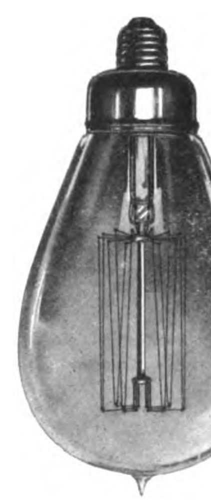
The twenty-five-watt tungsten for standard lighting circuits is still a thing of the future. Until it is perfected, however, the twenty-five-watt tantalum lamp, which has proved commercially satisfactory on alternating-current circuits, is making an excellent substitute.

THE 250-WATT TUNGSTEN.

At the other end of the scale the new 250-watt tungsten is making a phenomenal record. This lamp of 200 candle-power replaces gas arcs or electric arcs, lamp for lamp, and with considerable saving in operating expense entirely apart from increased safety, convenience and the other inherent advantages of the incandescent lamp.

The cost per candle-power naturally becomes less as the size of the unit increases, while the saving per unit of illumination remains the same (2.25 watts saving per candle-power when compared to a 3.5-watts-per-candle carbon lamp).

As compared to carbon lamps for equal illumination the forty-watt tungsten saves enough at ten cents per kilowatt-



General Electric 250-Watt Tungsten Incandescent Lamp.

hour to pay for itself three times over, but the 250-watt lamp saves enough to pay for itself eight times over. Furthermore, the 250-watt filament is much thicker and stronger than in the smaller sizes. It is a happy coincidence that this lamp, which is the most active factor in replacing the strongest competitors of the incandescent lamp, should be the sturdiest, and therefore least subject to, perhaps the most frequently mentioned argument against its use—the bugbear of fragility.

OPERATING COSTS.

The basis of all comparison is the actual saving in watts per candle-power of light, but the cost of the lamp and its life are necessary factors in making a correct commercial investigation of the tungsten lamp's merits.

The accompanying table has been compiled from such general data, and may be found surprising in many of its items. Its most interesting feature, however, is found in the last line of the table, which shows that for the same number of candle-hours of light the total cost of power and lamps for carbon lamps is more than double that with tungsten lamps.

TABLE OF DATA AND COSTS FOR SERVICE WITH VARIOUS LAMPS.

	Carbon.			Gem.		Tantalum.	Tungsten.			
	16 C.P., 3.1 W.P.C.	16 C.P., 3.5 W.P.C.	32 C.P., 3.1 W.P.C.	20 C.P., 2.5 W.P.C.	40 C.P., 2.5 W.P.C.	20 C.P., 2 W.P.C.	32 C.P., 1.25 W.P.C.	48 C.P., 1.25 W.P.C.	80 C.P., 1.25 W.P.C.	200 C.P., 1.25 W.P.C.
Total watts	50	56	100	50	100	40	40	60	100	250
Hours life to 80 per cent rated candle-power	500	1,000	500	500	500	800	800	800	800	800
Cost of lamp	17¢	17¢	25.5¢	21.25¢	29.75¢	51¢	$1.23	$1.49	$1.70	$3.40
Kilowatt-hours during life	25	56	50	25	50	32	32	48	80	200
Cost of renewals per kilowatt-hour	0.68¢	0.30¢	0.51¢	0.85¢	0.595¢	1.6¢	3.84¢	3¢	2.11¢	1.7¢
Cost per 100 hours' service for power at 10 cents per kilowatt-hour	50¢	56¢	$1.00	50¢	$1.00	40¢	40¢	60¢	$1.00	$2.50
Total cost of power and lamps per 100 hours' service at 10 cents per kilowatt-hour	53.4¢	57.7¢	$1.05	54.3¢	$1.07	46.4¢	55.3¢	78.5¢	$1.21	$2.925
Candle hours during life	7,350	14,700	14,720	9,200	18,400	14,720	23,680	35,520	60,000	150,000
Cost of power per 100 candle-hours at 10 cents per kilowatt-hour	3.4¢	3.8¢	3.4¢	2.7¢	2.7¢	2.17¢	1.36¢	1.36¢	1.36¢	1.36¢
Cost of renewals per 100 candle-hours	0.23¢	0.12¢	0.17¢	0.23¢	0.16¢	0.35¢	0.50¢	0.41¢	0.28¢	0.226¢
Total cost of power and lamps per 100 candle-hours at 10 cents per kilowatt-hour	3.63¢	3.92¢	3.57¢	2.93¢	2.86¢	2.52¢	1.86¢	1.77¢	1.64¢	1.586¢

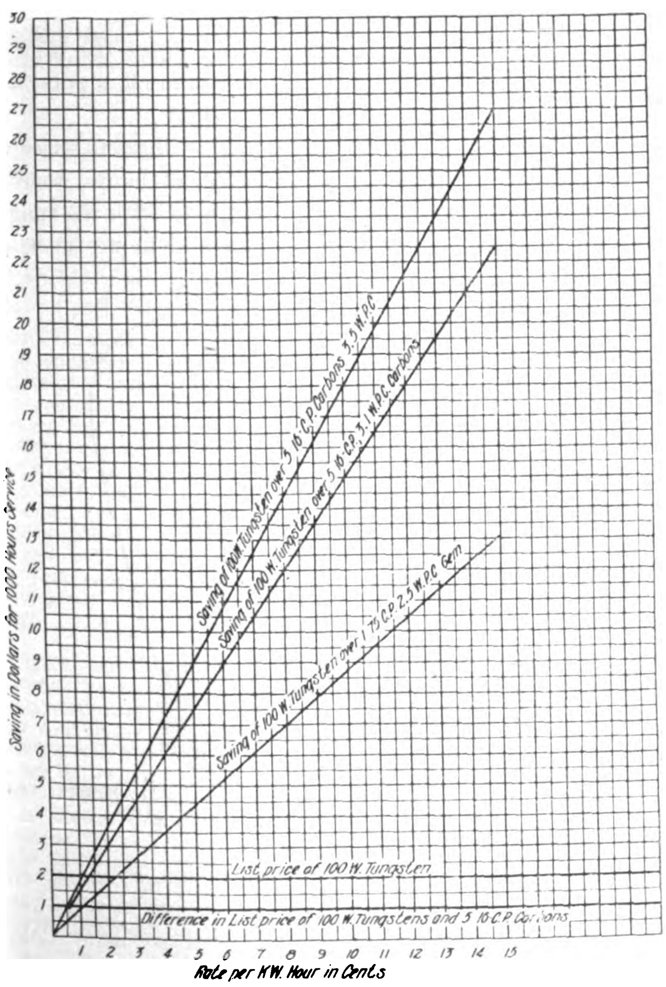


FIG. 1.—DIAGRAM SHOWING SAVING OF 100-WATT TUNGSTEN LAMP, AT EQUIVALENT CANDLE-POWER, OVER GEM AND CARBON LAMPS, AT DIFFERENT RATES PER KILOWATT-HOUR.

SOME STRIKING COMPARISONS.

Two diagrams are given herewith which illustrate the advantage of high-efficiency lamps, the eighty-candle-power, 100-watt tungsten being taken as the unit of comparison.

Fig. 1 shows the saving for equal illumination secured by the 100-watt tungsten over carbon lamps at various rates per kilowatt-hour. The curves are based on a life for the tungsten lamp of 1,000 hours and it will be seen at what an extremely low rate the tungsten lamp will pay for itself in saving of energy. Horizontal lines at the bottom of the diagram give the list price of the 100-watt tungsten and also the difference in list price between the tungsten and sufficient carbon lamps to give equivalent candle-power. The points at which the diagonal lines cross these horizontal lines give, respectively, the rates necessary for the tungsten lamp to save its entire cost and its extra cost over carbon lamps.

Fig. 2 is a comparison of the cost for 100 candle-hours' service of the 100-watt tungsten lamp, the 100-watt carbon lamp, the 100-watt Gem lamp and the forty-watt tantalum lamp at different rates per kilowatt-hour.

TUNGSTEN BATTERY LAMPS.

A very wide field has been found for the tungsten lamp in low-voltage and miniature types, where the high efficiency of the tungsten filament gives ideal results. In these lamps the low voltages permit the use of shorter and stronger filaments, and render the lamp able to withstand shocks and jars to much better advantage. In fact, they are being used extensively in automobile service, where

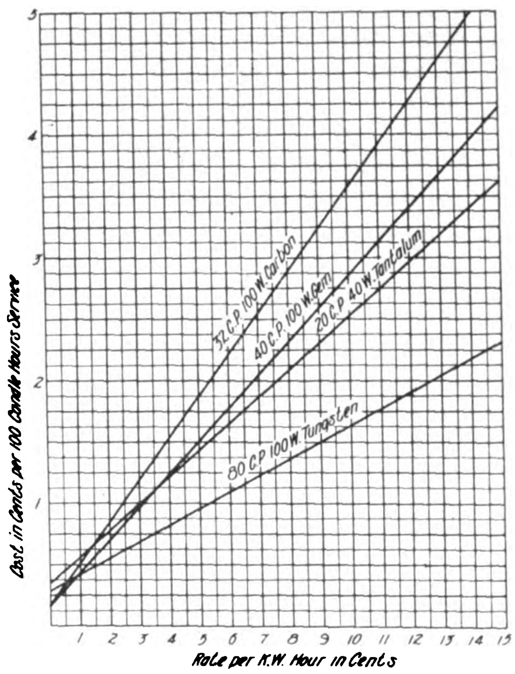

FIG. 2.—COMPARATIVE CURRENT COSTS FOR 100 CANDLE-HOURS OF SERVICE WITH TUNGSTEN, TANTALUM, GEM AND CARBON LAMPS.

the reduction of requisite battery capacity is of great value.

The efficiencies of the low-voltage and miniature lamps run from one to one and one-quarter watts per candle, with lives corresponding to those of carbon lamps of the same candle-powers and voltages. Besides giving three times the light of carbon lamps, the superior brilliancy and whiter color makes them much more desirable for many purposes.

In surgery the small tubular tungsten lamps give a more brilliant light and are cooler than carbon lamps.

In automobile service small lamps for side lights, for tail lights, instrument illumination, etc., can be operated satisfactorily from the ignition storage battery, and where auxiliary lighting batteries are used much cost and weight are saved by installing tungstens.

The numerous advantages of electric lamps in automobiles, including cleanliness, safety, convenience in lighting, reliability, etc., have made the tungsten battery lamps, which can replace oil lights without an excessive battery equipment, very attractive to automobile users. Adapters have been devised for changing oil burners into electric fixtures, and a simple wiring scheme completes the outfit.

Novelty lamps for dry-battery service are made with the tungsten filament for a great variety of purposes, and can be used in flashlights, pocket-lamps, portables, night-lamps, and a variety of specialties manufactured by the trade.

The accompanying illustrations show samples of some different types of tungsten miniature and battery lamps. They can be obtained in round and pear-shaped bulbs and in special shapes and candle-powers, and in a great variety of voltages, mounted on either miniature or candelabra bases.

While American-made miniature tungstens have been on the market but a few months, many new uses are being constantly found for them, the great reduction in battery capacity making them suitable for purposes for which electric lamps were formerly impracticable.

TUNGSTEN STREET SERIES LAMPS.

Little has been written regarding the tungsten lamp for street series circuits, and the following comparisons have been compiled to bring out the remarkable saving obtained by this new factor in the street-lighting field.

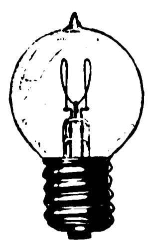
The value of the incandescent lamp in suburban districts is now generally conceded. The arc lamp has its place in densely populated districts (where the walls of the houses are close to the curb and by reflection eliminate dark shadows) and in locations where the required quantity of illumination warrants the units being placed near together.

In the less densely populated portions of our cities, however, the adoption of the arc lamp on an economical basis necessitates such great distances between the poles that evenly distributed and efficient illumination is impossible.

The tungsten series lamp is remarkable in many respects, and the success it has had from the first is a thing that has not often been duplicated in the electrical field. Long life results have been obtained, the average minimum being 1,200 hours, including all renewals, breakages, etc., and the average maximum over 2,000 hours, the general average being above 1,500 hours. These figures are not the result of a few installations, but of many thousand lamps.

Another remarkable quality of the lamp is that it maintains its candle-power practically constant, there being no blackening, which not only is a good feature while the lamp is burning, but gives it a much better appearance when the lamp is not lighted. This quality also allows the lamp to be used until it fails, and, together with its long life, reduces the labor cost of trimming to a minimum, a point which should not be lost sight of.

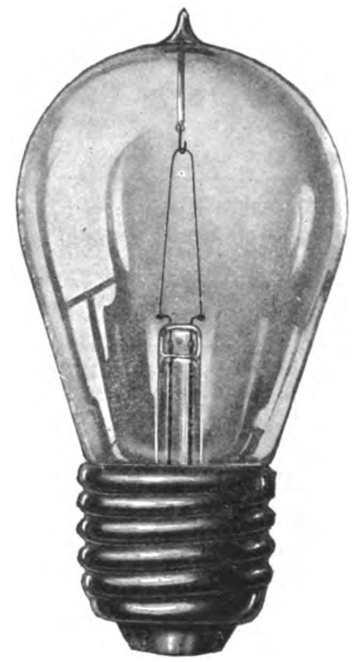
NOVELTY TYPE, STYLE G-3½, ONE-HALF TO ONE AND ONE-HALF CANDLE-POWER, ONE AND ONE-HALF TO THREE AND ONE-HALF VOLTS.



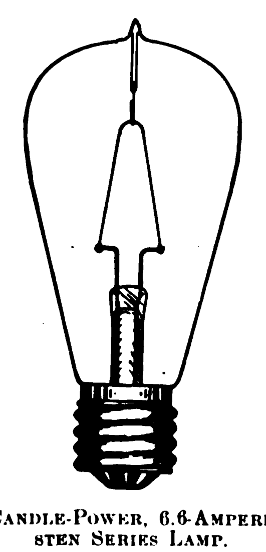
GENERAL BATTERY LAMP, ROUND STYLE, ONE TO FOUR CANDLE-POWER, FOUR TO SIX VOLTS.

GENERAL BATTERY LAMP, ROUND STYLE, FOUR TO TEN CANDLE-POWER, FOUR TO EIGHT VOLTS.

GENERAL BATTERY LAMP, STYLE P-8, FOUR TO TEN CANDLE-POWER, FOUR TO EIGHT VOLTS.

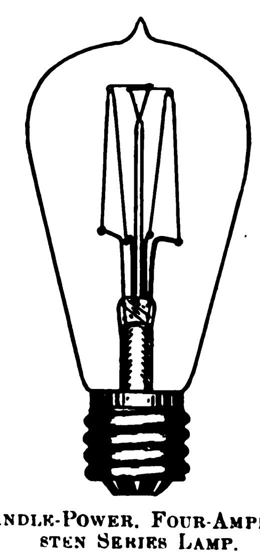


TUNGSTEN BATTERY LAMP WITH STANDARD EDISON BASE, FOUR TO TWENTY VOLTS.



FORTY CANDLE-POWER, 6.6-AMPERE, TUNGSTEN SERIES LAMP.

In comparing the tungsten series with carbon and Gem series lamps, there are two distinct advantages with the tungsten lamp, if actual costs alone are to be considered. The first is the saving in kilowatt-hours during a period of, say, a year's time, which is worth so many dollars according to the rate per kilowatt-hour for current. The other is the saving in capacity of station apparatus, or in other words, the station apparatus has a capacity



SIXTY CANDLE-POWER, FOUR-AMPERE, TUNGSTEN SERIES LAMP.

of three times the number of carbon lamps previously used. The former is a very large item where the generating costs, line losses, etc., are high, and the latter where the constant-current transformers are nearly fully loaded and it is desired to put on extra lamps in excess of their capacity.

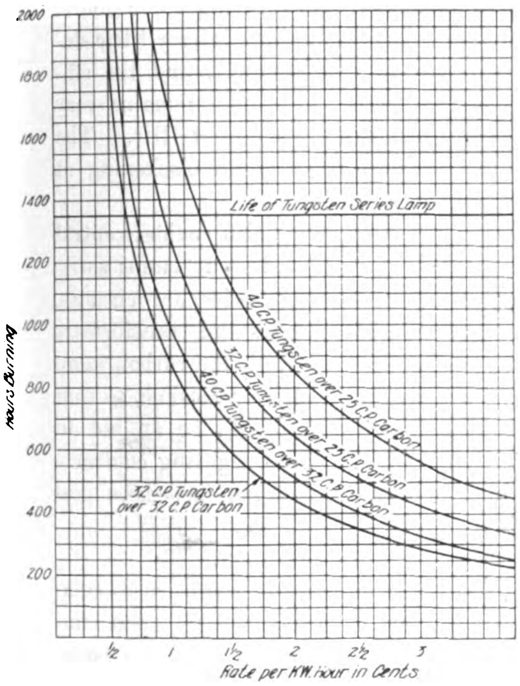


Fig. 3.—Life Necessary to Compensate for Increased First Cost of Tungsten Over Carbon Series Lamps, at Different Rates per Kilowatt-Hour.

THE SAVING IN POWER.

Following are illustrations of the saving in kilowatt-hours of the tungsten over the carbon and Gem series lamps:

A thirty-two-candle-power carbon lamp consumes in watts	112
A thirty-two-candle-power tungsten lamp consuming forty watts gives a saving in watts of	72
For 4,000 hours' service per year this gives a kilowatt-hour saving of	288
Value of saving at two cents per kilowatt-hour	$5.76
Net additional cost per year of tungsten renewals (three renewals tungsten, four renewals carbon)	$1.85
Net saving per year for tungsten over carbon	$3.91

A thirty-two-candle-power Gem lamp consumes in watts	86.4
A thirty-two-candle-power tungsten lamp consuming forty watts gives a saving in watts of	46.4
For 4,000 hours' service per year this gives a kilowatt-hour saving of	185.6
Value of saving at two cents per kilowatt-hour	$3.71
Net additional cost per year of tungsten renewals (three renewals tungsten, four renewals Gem)	$1.62
Net saving per year for tungsten over Gem	$2.09

THE SAVING IN APPARATUS CAPACITY.

As an illustration of the value of the saving in apparatus capacity the following possible gain in income will serve as an example.

With apparatus capacity sufficient for 100 thirty-two-candle-power carbon lamps (3.5 watts per candle), a station could supply 280 thirty-two-candle-power tungsten lamps. Assuming $30 per lamp per year revenue, the possible gain in income from additional tungsten lamps would be as follows:

COMPARATIVE INCOME.

Income from investment in apparatus for 100 carbon lamps at $30	$3,000.00
Possible income from same investment in station apparatus for 280 tungsten lamps at $30	8,400.00
Possible gain in income	$5,400.00

COMPARATIVE EXPENSE.

Tungsten lamp renewals at $1.27½, net, each, three per year for 280 lamps	$1,071.00
Fixed charges per year on additional line equipment for 180 additional lamps	150.00
	$1,221.00
Less expense of carbon renewals at 49.3 cents net, each, four per year for 100 lamps	197.20
Net additional expense	$1,023.80

NET GAINS FOR TUNGSTEN.

Hence net gain in income on each 100-light (carbon) capacity of apparatus is $5,400 less $1,023.80	$4,376.20
This gives a possible income per lamp station capacity now earning but $30 per year of	73.76
Or possible income per kilowatt-hour after the extra cost of tungsten renewals has been deducted ($73.76 ÷ 112 watts × 4,000 hours)	16.4
The present income per kilowatt-hour with carbon lamps is—$30 ÷ 112 watts × 4,000 hours.	6.7
The income per kilowatt-hour, if an equal number of forty-candle-power tungsten lamps are used in place of thirty-two-candle-power carbon lamps, after the extra cost of tungsten renewals has been deducted is— $\frac{\$30.00 - (3 \times 1.27\frac{1}{2} - 1.97)}{50 \text{ watts} \times 4{,}000 \text{ hours}} =$	14

Fig. 3 and Fig. 4 show the number of hours at various rates per kilowatt-hour a tungsten series lamp must burn to exactly pay its increased cost. Should the lamp last any longer than this, there is a thing that heretofore had been impossible. Twenty-five-candle-power carbon lamps have been used, but this has not satisfactorily met the situation. At rates of from $20 to $35 per year for 4,000 hours' (all night, every night) service for

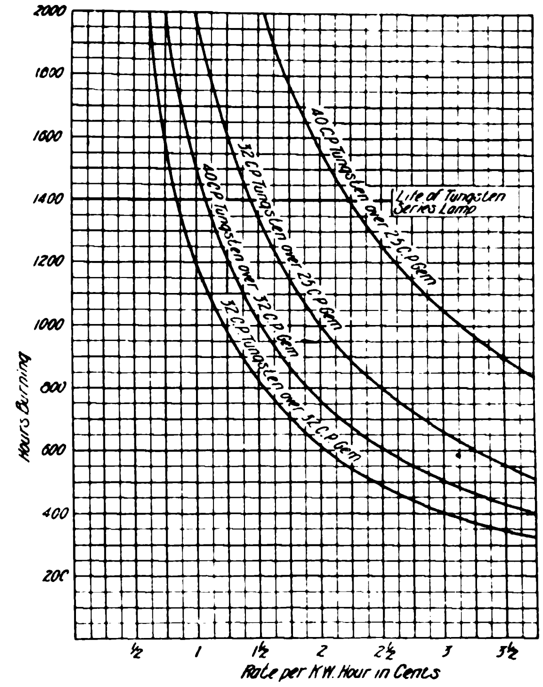

Fig. 4.—Life Necessary to Compensate for Increased First Cost of Tungsten Over Gem Series Lamps, at Different Rates per Kilowatt-Hour.

gas-mantle lamps, only a very low rate per kilowatt-hour is obtainable with carbon lamps to meet this cost.

Although the mantle is rated at sixty candle-power, tests recently made in three New England cities on the gas-mantle street lamp while operating under actual service conditions show, as the following figures indicate, a wide variation in candle-power:

City.	Maximum C-P.	Minimum C-P.	Average C-P.
(1)	55.0	21.5	36.7
(2)	25.0	6.5	16.8
(3)	55.1	16.3	27.8

RATES OBTAINABLE WITH FORTY AND SIXTY CANDLE-POWER LAMPS.

Income per year	$20	$22	$24	$26	$28	$30	$32	$34	$36
Rate per kilowatt-hour with forty-candle-power tungsten series lamps	8.8c.	9.8c.	10.8c.	11.8c.	12.8c.	13.8c.	14.8c.	15.8c.	16.8c.
Rate per kilowatt-hour with sixty-candle-power tungsten series lamps	5.4c.	6.0c.	6.7c.	7.7c.	8.0c.	8.7c.	9.4c.	10.0c.	10.7c.

an actual net saving during every moment of its use.

There is no doubt that the tungsten lamp enables central stations to compete with the gas and gasolene mantle lamps at very profitable rates per kilowatt-hour,

Hence a forty-candle-power tungsten lamp which maintains candle-power practically constant throughout life will give better average illumination than the mantle lamps in any of the above cases.

The accompanying table shows the rates

that can be obtained with forty and sixty-candle-power tungsten lamps covering power and labor, the cost of tungsten renewals (three per year) having been deducted.

Very few cities supply a mantle lamp for less than $25 per annum, and, as the above table indicates, both the forty and sixty-candle-power tungsten lamps can easily compete with it profitably.

Another way of illustrating the above will be found in the following figures showing the cost of supplying a mantle lamp and the income for current obtainable to exactly meet it.

Consumption of gas per hour of mantle lamp	3½ cu. ft.
Cost of gas at $1 per thousand for 4,000 hours' service per year...	$14.00
Renewals, repairs and labor at three cents per night per year (figures given in a recent city contract)	10.95
Total cost per year gas mantle.	$24.95

The possible rate per kilowatt-hour obtainable with the forty-candle-power tungsten series lamp to exactly meet the above cost is as follows:

Income per year per forty-candle-power tungsten lamp	$24.95
Three renewals at $1.27½ per lamp per year	3.83
Income per lamp per year to cover cost of power, labor and repairs	$21.12
A forty-candle-power tungsten lamp consumes in watts	50
For 4,000 hours' yearly service it consumes in kilowatt-hours	200
Hence rate obtainable per kilowatt-hour for power, labor and repairs is $21.12 ÷ 200, or over.	10.5 cents
Similarly the rate per kilowatt-hour obtainable for the sixty-candle-power (seventy-five-watt) tungsten series lamp, to cover cost of power, labor and repairs is $21.12 ÷ 300, or over	7 cents

The cost of producing a candle-hour of light with the tungsten series lamp is considerably less than the carbon lamp, as is shown relatively in Fig. 6. These values are determined on the differential basis

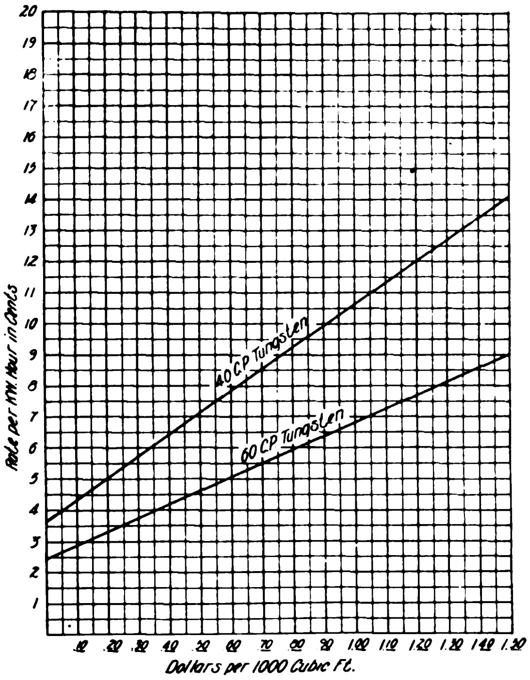

Fig. 5.—The Rate per Kilowatt-Hour Obtainable for Forty and Sixty-Candle-Power Tungsten Series Lamps to Meet the Cost of the Welsbach Mantle at Various Rates for Gas for 4,000 Hours' Yearly Service.

for various hours' use of lamp per year, and cover:

First—Generating cost proportional to output covering fuel and station labor costs at a value (at the lamp) of one cent per kilowatt-hour.

Second—Fixed charge on investment in generating apparatus taken at twelve per cent on $125 investment per kilowatt of capacity, giving a value per kilowatt of apparatus of $15 per year.

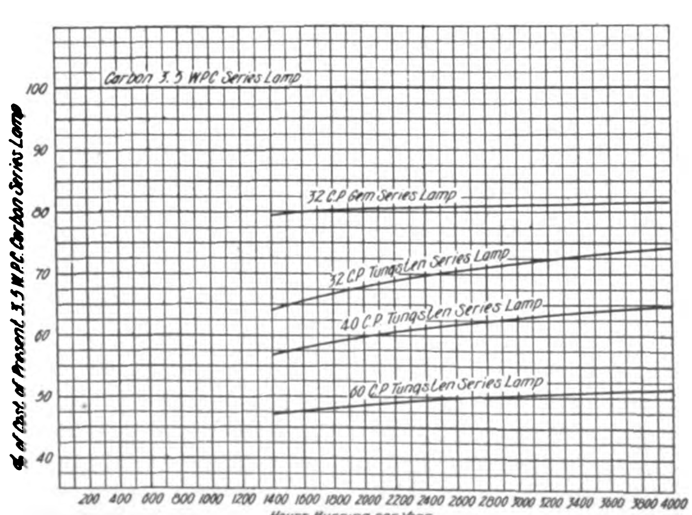

Fig. 6.—Relative Cost of Producing a Candle-Hour of Light—Tungsten Versus Gem and Carbon Series Lamps.

The curves in Fig. 5 show the above graphically at various rates for gas.

Third—Renewal costs of lamps as estimated from the following prices:

Carbon lamp	$0.54
Gem lamp	.65
Thirty-two-candle-power tungsten lamp	1.50
Forty-candle-power tungsten lamp	1.50
Sixty-candle-power tungsten lamp	1.50

The candle-power and efficiency curves of the tungsten lamp during 2,000 hours' burning shows that there is very little depreciation in candle-power, and the efficiency in watts per candle remains very nearly constant throughout life. The lamps show practically no blackening at the end of the test.

The tungsten lamp also enables central stations to put incandescent lamps satisfactorily on existing series arc circuits, so that separate circuits and transformers are not necessary. With the carbon lamp this has not been entirely feasible, so that the tungsten lamp should be an aid in getting suburban street lighting contracts which heretofore may not have been possible.

CONCLUSION.

The tungsten lamp is unique in its combination of advantages—the great improvement in efficiency it secures being followed by gains instead of losses in other desirable characteristics.

The increase in efficiency is accompanied by lengthened life with a better maintenance of candle-power than in carbon lamps. The quality of the light, furthermore, is more brilliant, and instead of showing objectionable peculiarities is unsurpassed in its resemblance to sunlight.

The high efficiency of tungsten lamps does not make them susceptible to slight changes in voltage, but, on the contrary, the positive temperature coefficients of metallic filaments render them less liable to the effects of poorly regulated circuits.

With such a list of good points added to its remarkable economy, there can be no doubt that the tungsten lamp is here to stay.

Its improvement in quality in one year of American activity has been so great that predictions of future improvements, however enthusiastic, could hardly be called exaggerations, and remembering the early days of the carbon lamp the present characteristics of the tungsten seem remarkably free from faults.

Electric Traction in the Bernese Alps.

An appropriation of $200,000 has been made by the Bernese Alps Railway Company for the installation of electric traction between Spiez and Frutigen, on the northern approach to the Loetschberg tunnel. It is intended to use fifteen-cycle single-phase current at 15,000 volts line pressure. The current will be obtained from the Kander & Hagneck hydraulic plant at Spiez. The maximum gradient in the tunnel is 2.7 per cent.

Cooper Hewitt Lamp Progress.

SINCE its introduction into the field of illumination, the Cooper Hewitt mercury vapor lamp has undergone continual development, and, year to year, there have been evolved new types which have been the natural evolution of close application and keen scientific investigation in the effort to supplement the original high efficiency with ease of manipulation and invariability of service. The theory of operation and the characteristics of the mercury vapor lamp are well understood, and the present article will deal specifically with the mechanical construction of the lamps which are available to-day for commercial service.

One of the improvements with which the lamp is at present equipped is a self-contained adjuster, which affords an economical and uniform current regulation, placed in an easily accessible position in the cylindrical casing which forms an integral part of the lamp fixture.

To avoid the method of tilting the lamps by hand to start the arc, which is quite practicable where the lamps can be easily reached, but is hardly feasible when the lamps are placed in inaccessible positions, an automatically tilting lamp, type H, has been produced. This lamp is illustrated in Fig. 1. When the line switch is closed an electromagnet is energized and a movable iron plunger tilts the lamp. When the arc is established the solenoid is automatically cut out.

This method is adaptable particularly where short lamps are used, and is supplemented for universal service by an automatic shifter starting method. The shifter is so-called because it shifts the current from its own circuit to that of the lamp. This starting method, briefly, consists in the introduction of the arc through the medium of a high-potential kick. This method of starting has been developed to such a point that the starting of the arc and the satisfactory operation of the lamp are invariable.

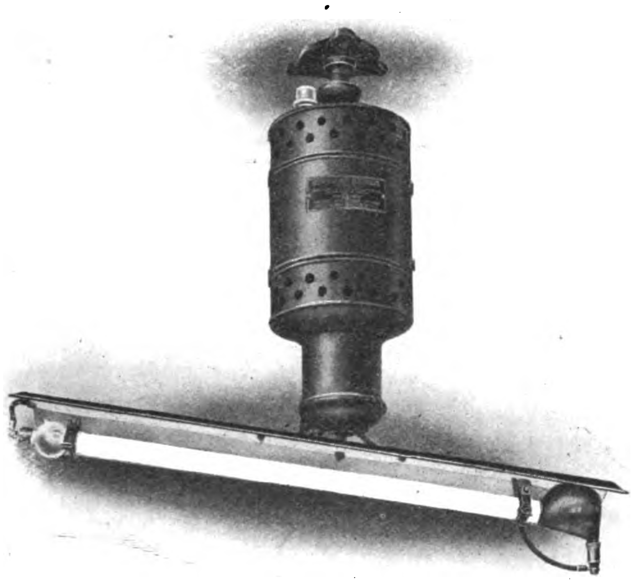

Fig. 1.—Cooper Hewitt Type "H" Automatic-Tilting Mercury Vapor Lamp.

Three new types of lamps, all equipped with the starting method just indicated, are designated as type P, type U and type F. The type P lamp is shown in Fig. 2. This lamp is designed to operate on 100 to 120-volt circuits, and has a mean hemispherical intensity of 800 candle-power on 110 volts, the current consumption being three and one-half amperes.

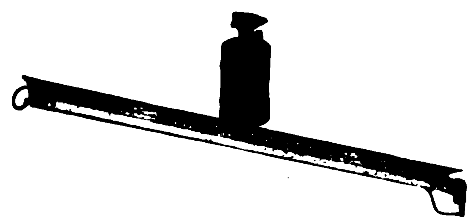

Fig. 2.—Cooper Hewitt Type "P" Mercury Vapor Lamp.

The type U lamp, shown in Fig. 3, is calculated for the double voltage of the type P lamp. The construction of this lamp is similar to that of type P, with the exception of the difference in the physical form of the U-shaped vacuum tube. The lamp consumes two amperes on 220 volts, and has a luminous intensity of 900 mean hemispherical candle-power.

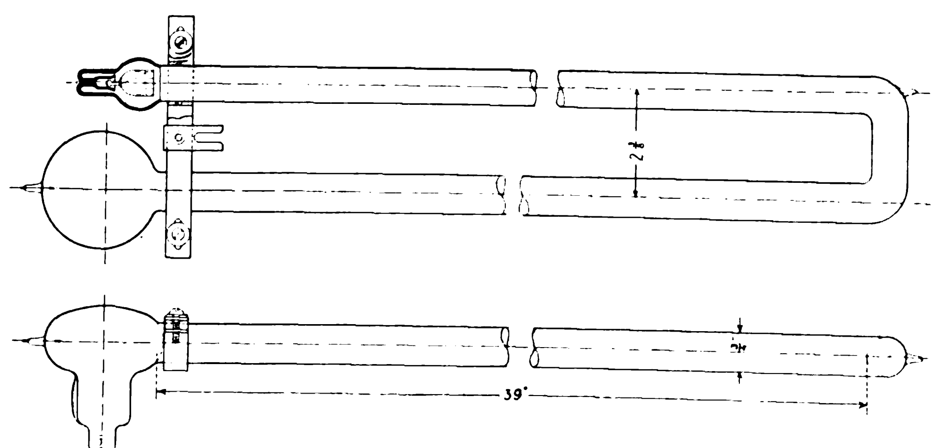

Fig. 3.—Representation of Type "U" Cooper Hewitt Mercury Vapor Lamp.

Upon the principle of the mercury rectifier, the mercury vapor lamp is adaptable to use with alternating currents. Any difficulty which was experienced with the alternating-current mercury vapor lamp, due to trouble in starting, has been overcome by the use of the new shifter method. The alternating-current lamp, the type F, (Fig. 4) is similar in appearance and construction to the type P lamp, but, like a rectifier, has two positive (iron) electrodes connected to a transformer, the middle point of which leads over an adjuster and two inductance coils to the negative (mercury) electrode. The inductance serves in this case both for the starting of the lamp and the damping of the current pulsations on the negative running arc. The auxiliary apparatus is similar to that used with the type P lamp, but a transformer is added, and this is generally made an integral part of the outfit, but in exceptional cases can be supplied as a separate installation. This lamp is designed in six types, for various voltages, and consumes, on the mean voltage for each respective type, 400 watts with a mean hemispherical illumination intensity of 800 candle-power and a primary power-factor of eighty-three per cent.

A summary of the present installations of the Cooper Hewitt mercury vapor lamp indicates that it is being used successfully for the illumination of almost every conceivable character of interior industrial illumination. It has been found particularly adaptable to the illumination of large areas where a high quality of lighting is necessary for the carrying on of

Fig. 4.—Cooper Hewitt Type "F" Mercury Vapor Lamp.

processes requiring close inspection. One of the most recent successful invasions of this lamp is in silk-mill illumination. As far as the process of making silk is concerned, it is not so much a question in the mill of matching colors as it is of securing a uniform product and detecting at once any variation in the physical character of the silk threads. The testimony of silk makers who have used this form of illumination is to the effect that the peculiar quality of the mercury vapor lamp renders it very easy to detect any flaws which may develop in the textile during the process of manufacture.

Electricity Supply in Marseilles, France — The Brillanne-Villaneuve Hydroelectric Station.

The Brillanne-Villaneuve hydroelectric station, which partly supplies Marseilles with electrical energy, is described by J. A. Montpellier in *L'Electricien* (Paris), August 22, for the benefit of electricians who will visit that city during the coming International Congress of Applied Electricity. The station is situated near the community of Brillanne, on the banks of the River Durance, from which water is taken at the rate of sixty cubic metres per second to a head reservoir through a canal starting eight kilometres above the station. From the head reservoir the water flows into five large sheet-steel pipes, eighty metres long and 2.70 metres in diameter, each one of which feeds one of the groups of generators. A sixth pipe, 1.2 metres in diameter, feeds the turbine driving the exciters. The turbines are of the two-wheel Francis type, each installed in a separate water chamber, but all having one common discharge channel. They can generate 3,500 effective horse-power each under a head of twenty-two metres at an angular velocity of 250 revolutions per minute. Each turbine is directly coupled to an alternator. The exciters are driven by Francis turbines of 250 horse-power. The station is to contain five generator units, of which four are at present in operation. The dynamos are three-phase alternators of 3,000 kilowatts, furnishing a current of 7,500 volts and twenty-five periods a second. The exciter is a 200-kilowatt, direct-current machine giving 110 to 125 volts. On account of the high tension adopted on the transmission line, 52,000 volts at the station, the transformers are installed in a separate building, which occupies a space of 1,100 square metres, while the generating station occupies 1,000 square metres. Each alternator is connected by a paper insulated, lead-covered cable with three conductors to a group of three single-phase transformers, of a capacity of 900 kilowatts each and a ratio of transformation of one to four. By a triangle connection in the primary circuit and a star connection in the secondary they raise the tension between phases from 7,500 to 52,000 volts. The transformers had to be constructed with particular care and required special precautions for cooling. Their windings are immersed in oil and the oil is cooled by the circulation of cold water through a coiled pipe. Automatic devices indicate any abnormal rise of temperature in the oil at the station. The current from each group of transformers can be led to either one of two series of bus-bars, from which the 52,000-volt, three-phase transmission lines branch off and leave the building from special bays in which Wirt lightning arresters are installed. All the high-tension circuits are controlled by special three-pole circuit-breakers, which are operated by small direct-current motors by means of cogs and levers, a double break taking place in oil and each phase being in a separate brick compartment. A 10,000-kilowatt current at 52,000 volts can be thus interrupted without deteriorating the contacts. The small motors operating the circuit-breakers can be controlled at will from the switchboard, and the circuit-breakers also open automatically when the current rises to a dangerous intensity. All the controlling, regulating and measuring instruments are placed on the main switchboard of the station. The safety of the attendants is insured by the fact that all of these apparatus, without exception, operate under 110 to 125 volts, direct current being used for the motors actuating the circuit-breakers, and the alternating current being reduced by tension and intensity transformers. Three high-tension transmission lines leave the station, going, respectively, to Allauch, Arles and Marseilles. The line supplying Marseilles is over 100 kilometres long and the tension of 52,000 volts is the highest so far adopted in Europe. The plant has been in operation for over four months, so far without incident. All the machinery and apparatus have been supplied by the French Thomson-Houston Company.

The Empire State Gas and Electric Association.

The annual meeting of the Empire State Gas and Electric Association will be held in the Engineering Societies Building, New York city, on October 7. Among the subjects to be discussed are the following: "Public Policy Work of the Association;" "Standards for Gas Service and Standards for Electric Service, Taking as a Basis the Recent Rules of the Railroad Commission of Wisconsin;" "Taxation of Gas and Electric Companies in New York State, with a Report from the Taxation Committee;" "Insurance of Gas and Electric Stations;" "Review of the Decisions of the Public Service Commissions;" "Electric Meter Testing, with Report from the Meter Committee;" "Accounting, with Report from the Accounting Committee;" amendments to the constitution and by-laws, with a new schedule of annual dues; affiliation with the American Gas Institute and the National Electric Light Association.

The secretary of the association is Charles H. B. Chapin, 154 Nassau street, New York city.

The New Westinghouse Nernst Lamp.

By Otto Foell.

IN the 1907 "Electric Lighting and Illuminating Engineering Number" I presented to the readers of the ELECTRICAL REVIEW the commercial status of the Nernst lamp. In the interim we have witnessed great activity on the part of lamp manufacturers to improve the efficiency of the incandescent units.

The Nernst lamp has kept pace with the demand for increase in economy. Great progress has been made during the past year in the application of the Nernst glower principle, and to-day I am prepared to outline some new features of Nernst lamp practice which, with the mechanical improvements embodied in the designs, make the new Westinghouse Nernst lamps the most efficient and economical lighting system, as by their use the total cost of light (current plus upkeep) is reduced to the lowest point ever reached by incandescent lighting units.

FIG. 1.—MULTIPLE-GLOWER WESTINGHOUSE NERNST FIXTURE LAMP WITH SQUARE CANOPY AND CHAIN.

The principle of the Nernst lamp is well understood by this time.

The incandescent body or glower is a non-conductor for electricity when cold but becomes a good conductor when heated and remains a current conductor by reason of the energy dissipated in the filament.

The lamp body contains the parts for starting the glower and for current control, the former being an electric heater with automatic cutout, the latter a small iron wire resistance mounted in a glass container, exhausted and then filled with an inert gas.

When first introduced, four standard sizes of lamps were manufactured for operation on alternating current: a six-glower lamp, a three-glower lamp, a two-glower lamp and a single-glower lamp, varying in mean lower hemispherical efficiency from 1.64 watts per candle-power to 2.54 watts per candle-power, this efficiency data based on lamps equipped with alabaster or diffusing glassware.

A little later the four-glower lamps were brought out to meet a want for a unit between the three and six-glower sizes.

The bunching of glowers in parallel on one burner or holder created an incandescent unit which gave the lamp a wide field of usefulness.

About a year ago the 110-watt Nernst was introduced. This unit marked one great step toward realizing a higher glower efficiency. Its general success led to the present perfection of a complete line of lamps.

Coincident with the marketing of the 110-watt unit, the advent of the direct-current Nernst lamp was announced. These direct-current units are now used in large numbers and among the prominent installations I desire to mention the great store of Marshall Field & Company, in Chicago, where 12,000 units are employed.

It should be remembered that the glower, being a conductor with negative temperature coefficient, requires for current control a highly sensitive ballast resistance, and upon the ability of this resistance to perform its function properly depends to some extent the glower life performance.

Users of the standard Nernst lamp are probably aware of the fact that immediately upon lighting the amount of light emitted is far in excess of the rated candle-power of the lamp. This is caused by an excess current flowing through the glower, the current gradually decreasing until the lamp attains normal operating temperature.

In the new Westinghouse Nernst lamp a great improvement in electrical performance has been attained. That is, the individual life performance of the glower has been improved, ballast troubles have been reduced and the heater has been made of such proportions and such lasting qualities that a lamp once installed will need very little attention. The combination of these properties naturally results in a lower maintenance cost.

The features just mentioned, even without improved efficiency, would make the Nernst lamp a very attractive commercial lighting proposition. We, however, did not stop in merely improving the electrical performance and reducing the maintenance cost, but succeeded in materially increasing the efficiency of the lamps. Hand in hand with these improvements there was an improvement in the mechanical arrangement of the different lamp parts, so that the Westinghouse Nernst lamp of to-day represents a unit of high efficiency, good electrical performance and low maintenance cost.

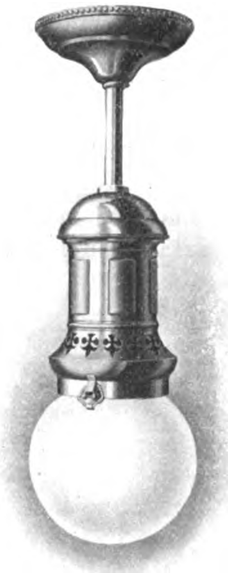

FIG. 2.—MULTIPLE-GLOWER WESTINGHOUSE NERNST FIXTURE LAMP WITH ROUND CANOPY.

Before I go into a detailed description of the different Westinghouse Nernst units available for commercial use, I shall deal generally with the principles of current control in the lamp and their influence on the performance of the glower.

Since the current through a glower is controlled by the ballast, it naturally follows that improvements in glower performance must begin in a better ballast performance. This may be accomplished by placing the ballast in a medium where its characteristic is not influenced by its surroundings.

In the standard Nernst lamps the ballasts are bunched. Their heat is emitted and radiated into an enclosed housing, tending to decrease the current capacity of the ballast. To offset this effect the ballast was designed to take a current, when cold, far in excess of its normal operating current. Moreover, the question of supporting the resistance wire was not very well understood and material was used in the construction of the ballast which tended to further decrease its current-carrying capacity.

In the Westinghouse Nernst lamps now available, this objectionable characteristic has been eliminated by so increasing the radiating surface of the ballast that the ballast characteristic is not influenced by its surroundings. The mechanical device consists of a number of phosphor-bronze pieces placed in a cooling cylinder and so formed that the contact surfaces firmly enclose the ballast. The heat liberated in the ballast is transmitted to the bronze pieces by contact, and from there it is radiated and conducted into the surrounding air.

The effect of this improvement in glower current control is readily noted immediately after lighting the Westinghouse Nernst units.

Hand in hand with improved current control came the improvement of the glower proper.

The glower of to-day is a radical departure from the glower used in the older lamps, both mechanically and in the composition of its constituent parts. Mechanically we have to-day a greatly improved terminal construction which reduces the terminal loss due to the Peltier effect approximately two-thirds. The result is a longer lighting length between terminals for a specific voltage. Moreover, a larger percentage of radioactive material is used in the glower, the properties of which have been recently established. Their addition to the glower mixture greatly increased the glower efficiency without materially increasing its operating temperature.

The characteristics of the new glower are about the same as those of the old glower, with the exception that its candle-power performance during life is more constant, which means Nernst lamps with only slight candle-power depreciation.

However, one feature not to be overlooked is the individual life performance of the new glower. Owing to their treatment during manufacture, glowers of old construction were more or less unreliable. While the average life performance of the glowers was all that was claimed for them, yet there were early failures. The new terminal successfully overcame this defect in the glower and failures during early life should be few and far between.

The ballast employed in the Westinghouse Nernst lamp is of rugged design. The iron resistance wire is enclosed in a bulb of increased diameter, so that an anchoring of the resistance wire other than on the terminals is unnecessary. These anchors, being metallic supports, have little heat capacity compared with the former porcelain disc anchor, and consequently give the ballast very quick action; that is, voltage variations of the circuits are immediately taken care of, thereby protecting the glower in the most sensitive way against possible overloads. On the other hand, the ballast itself is very well adapted to withstand voltage fluctuations without damaging it, a noteworthy and desirable feature.

Fig. 3.—Screw Burner for Westinghouse Nernst Lamp.

A mechanical detail to which I desire to call attention is that all ballasts are equipped with a bayonet socket, making their replacement an easy matter.

Fig. 4.—Single-Burner Westinghouse Nernst Lamp.

DESCRIPTION OF LAMPS.

The mechanical construction of the multiple-glower lamp presents a harmonious design, embodying simplicity and compactness. Unsightly exposed terminals are done away with and in their stead the insulating hook is provided with an opening through which the service wires enter the top of the lamp housing and terminate in two enclosed binding posts.

This construction makes it possible to use the lamp in connection with fixture work by substituting a special fixture nipple for the standard insulating hook. Fixture lamps are illustrated in Figs. 1 and 2.

Extending from the terminal construction is a tubing to which, by means of screws and washers, is fastened the middle part of the housing, containing the ballast coolers. Sliding up and down inside the tubing is a brass rod serving to support the lower part of the lamp body, including the ballast plate, contact plate for holder and globe-holder ring.

The sliding inner post is provided with a steel stop engaging in a slit of the tubing, serving to lock the two parts of the housing together by means of a hooking catch, which may be operated by the lever provided in the middle part of the housing.

This construction affords an easy access to the ballasts, as the latter are arranged to drop with the lamp body when it is lowered.

The cutouts are below the ballast porcelain and electrical connection between the terminals, and the ballast plate is made by means of a brass rod and brass tubing, the latter sliding up and down with the lower part of the lamp, insuring electrical connection at all times.

The alternating-current Westinghouse Nernst lamps are provided with two cutouts, one located in each side of the service line. The direct-current, multiple-glower Westinghouse Nernst lamps have one cutout only, opening the heater circuit at the positive side of the supply circuit.

The part of the lamp body containing electrical connections is fastened to the lower lamp housing by means of an accessible nut. This housing is arranged in such a way that it leaves insulated openings for the insertion of the holder.

The petticoat of the lamps, which serves at the same time as a globe-holding device, is composed of two main parts, an inside and an outside shell, which are of different diameters and arranged like two concentric rings, one inside the other, thus providing an opening for ventilation. The air for ventilating is drawn into the inside of the lamp housing through this opening and through the ornamental openings in the petticoat and leaves the lamp, after passing through the ballast coolers, through the outlets provided in the top part of the lamp housing.

The device for holding the globe to the lamp housing is similar in construction to the globe holder used in the arc lamp. It consists of a phosphor-bronze band which is fastened to the globe by means of screws. From this band two lips protrude which engage with properly shaped wire rings on the lamp body. The latter are pivoted eccentrically in movable stampings, which when moved simultaneously toward the lamp housing draw up the globe and hold it firmly in place. When lowering the globe, one lip of the globe band is easily disengaged, the globe swings freely on the other, thus giving ready access to the holder and facilitating rapid maintenance.

The holder of the Westinghouse multiple-glower units presents a radical change in design. The old two-piece porcelain holder is replaced by a one-piece holder base, to which are attached contact prongs as shown in Fig. 7. Two prongs are brought through the holder base and are secured in such a manner that they lie in a plane parallel to the glowers and at right angles to them. The use of two or more heater tubes is superseded by a wafer heater, a heater consisting of a small platinum-wound rod, which in turn is coated with refractory cement and bent into the form of a wafer, from which the heater obtains its name. The wafer is mounted securely to a flat porcelain. This porcelain is provided with contact sleeves,

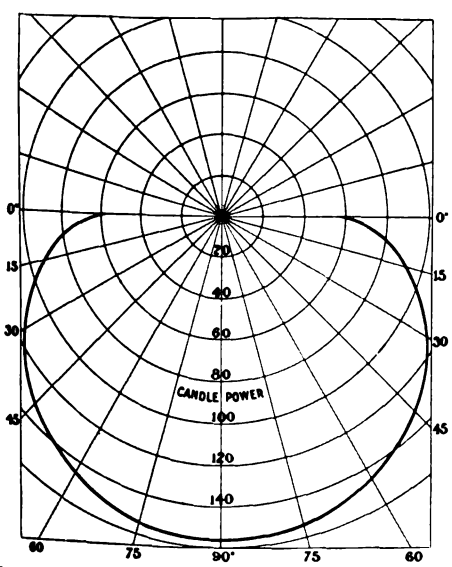

Fig. 6.—Distribution Curve of 132-Watt Type Westinghouse Nernst Lamp.

which engage with the heater prongs on the holder, holding it firmly by friction and at the same time making electrical connection. This design simplifies maintenance to a great extent as it allows the removal of the heater without disturbing the glowers, a feature which was not possible with the old-type holders. It is evident that such a holder means decreased

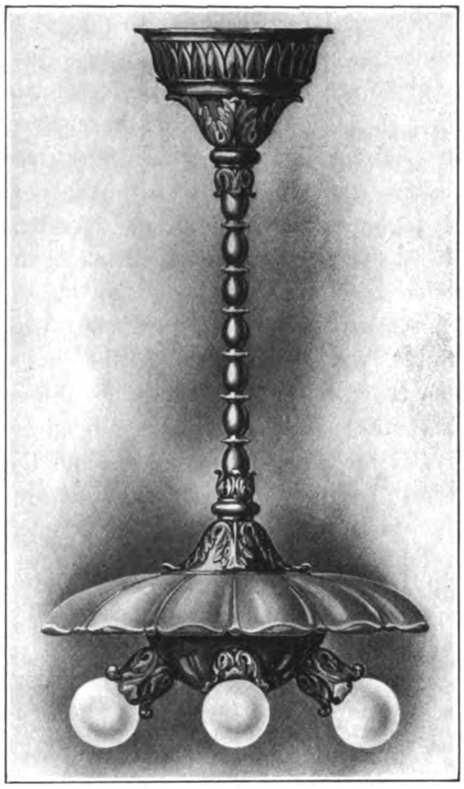

Fig. 5.—Fixture for Single-Glower Westinghouse Nernst Lamp.

cost of maintenance, a saving being made in both labor and material.

The various sizes of single-glower lamps are of the Edison base type, very similar in construction to the new popular 110-watt unit, but present a radical change in the method of maintenance, which is simple in the extreme.

In the bottom of the lamp housing is found a screw receptacle in place of the prongs formerly used in connection with the "push-type" holder.

The present holder consists of a glower and wafer mounted on a small porcelain with a screw base and provided with three contacts, the centre one of which is a pin. This renewal is popularly termed the "screw burner." See Fig. 3.

By an assortment of diameters and lengths of the contact pin, it is impossible to insert any other than the proper holder in the lamp body, thereby insuring the consumer against troubles incident to confusion from lamps of various voltages and current capacities.

The holder can be supplied with or without glassware of various sizes and density. This type of renewal will supply the popular demand for a high-efficiency incandescent lamp so rugged in its design that systems can be maintained by any one, and the renewals safely shipped by freight, mail or express. Fig. 4 shows the general appearance of the lamp.

The value of any lighting system does not depend, however, on its efficiency alone, but due consideration must be given to the cost of its maintenance. All other factors, such as life, being equal, a system having an efficiency for the same candle-power delivered may be preferable on account of its low maintenance cost, which may be so low that the increased cost of current consumed is more than offset by its lower maintenance cost.

The new Westinghouse Nernst lamp, which combines the highest efficiency (and with a daylight quality of light) with lowest maintenance, I believe, has no equal to-day in artificial lighting.

EFFICIENCY AND MAINTENANCE.

The efficiency of any lighting system is best expressed by the horizontal intensity of illumination produced by its light sources when suspended at a specified height above the test plane. That is, only light sent out by a lamp in a downward direction or its mean lower hemispherical candle-power can be considered. Therefore all figures for efficiency given below express the economy of the Westinghouse Nernst lamps in watts per mean hemispherical candle-power.

All holders for the new Westinghouse Nernst unit are designed along the same principles as have been consistently advocated by the Nernst Lamp Company since the advent of the Nernst lamp, namely, to give a downward distribution, with as

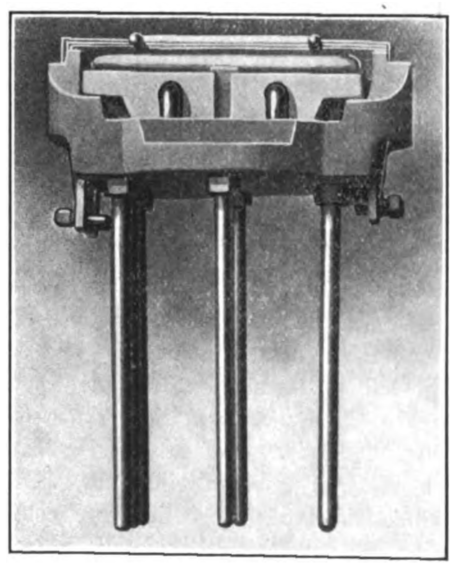

Fig. 7.—Westinghouse Nernst Multiple-Glower Wafer Heater Holder.

little light in the upper hemisphere as possible.

Consequently the glowers are arranged horizontally below the heater, thereby throwing almost the entire flux of light downward from the glower in the useful plane.

Fig. 6 gives the light distribution from a 132-watt direct-current type Westinghouse Nernst lamp equipped with clear glassware. This curve represents the average result of a number of holders and should be considered typical for this unit. The mean lower hemispherical candle-power is equal to 114.8 the corresponding efficiency being 1.2 watts per candle-power.

In comparing these figures with the data published for the old type two-glower lamp, it will be noted that the efficiency is increased from 2.05 watts per candle-power to 1.2 per candle-power, or a gain in light of forty-one and one-half per cent for equal energy consumed.

The efficiency per mean lower hemispherical candle-power of this unit is 1.07 watts, which is equal to 516 mean lower hemispherical candle-power. It will be noted that this unit is not only the largest incandescent unit on the market, but in every respect it delivers the most light for the energy consumed.

The distribution is ideal, especially for large interiors with high ceilings. A five-glower, 660-watt Nernst unit will also be placed on the market this year, having a still greater efficiency.

The figures for efficiency are somewhat modified when lamps are used with diffusing glassware. The latter case is the rule rather than the exception. I have given the efficiency figures for clear glassware to show what is possible with the new Westinghouse Nernst units and to establish a basis of comparison with other incandescent lamps.

A series of tests has been made to determine the visible spectrum of the glower when the light is passing through different opalescent globes. The combined efforts of the glass manufacturers and the Nernst Lamp Company laboratory resulted in an alabaster globe being adopted as standard, which gives a well-diffused light with the least loss in efficiency.

The light absorption in the special Nernst globe is about fourteen per cent. The character of the distribution curves is not changed materially, that is, the light emitted from a Westinghouse Nernst unit is decreased in the different vertical angles about fourteen per cent when equipped with diffusing glass as compared with clear globes.

In conclusion I want to say that the invention of the Nernst glower stimulated activity in all directions and to-day we have a number of incandescent lamps, of various efficiencies. While all the latter lamps are vacuum lamps and depend on a good vacuum for life performance, the distinct advantage of the Nernst glower lies in the fact that it is operative in the open air. It can be readily understood that such a principle must be the basis of all future developments in high-efficiency lamps.

The screw burner principle makes it possible to obtain very artistic and desirable combinations, also permitting the operation of the burners in any position.

To meet the demand for artistic fixtures the Nernst Lamp Company has developed a line of Westinghouse Nernst fixtures, which are available for alternating current or direct current, 110 or 220 volts. Fig. 5 illustrates one of the standard fixtures now ready for the market. It may be used with sixty-six, eighty-eight, 110 or 132-watt units.

The Illuminating Engineer as an Architectural Critic.

By Bassett Jones, Jr.

"NOTIONS of some sort," says Symonds, "underlie all judgments." By notions he means the organization of personality peculiar to each individual. This organization of the personal self determines the form of the active judging attitude we take toward experience. No two minds will perceive objects in the same way, unless the stock of "funded" truths which each possesses is each for each alike. New ideas can never be accepted as true unless the present organized facts of knowledge can be readjusted to make place for the new thought. This fact is at once the safeguard and the danger of society. We can live together in peace only in so far as the presuppositions of our beliefs are common, while, on the other hand, unless there is some diversity of attitude there can be no development and no advancement.

There will be, then, certain basic common attitudes—the attitudes we adopt toward justice, liberty, and morality for instance—which will form the substratum of the basis upon which the larger groups of society are founded. Above these fundamentals society will be found to break up into smaller and smaller sub-groups until the essentially personal attitude of the individual is reached. The active judging attitude of each group will determine the perspective in which reality is seen and will determine the aspects of reality that go to make up the world of knowledge common to the group. The validity of judgments is determined by whether or no the activity subsequent to and founded upon the judgment brings experience that fits into the world of knowledge, or the presuppositions which determine the judgment, and not upon whether or no this experience fits into some other scheme of knowledge foreign to the judgment. When such experience does fit, we say that the judgment is a true judgment. Truth is a meaning that attaches to the result of a valid judgment *per se*.

It then follows that attitudes can not be judged with relation to some form of funded knowledge that does not give rise to them, except and only in so far as the basis of the judgment is common to both attitudes, namely, the attitude judged and the attitude giving rise to the judgment.

Society is grouped, then, according to the attitudes toward experience common to the individuals forming the group. Thus scientists possess in common one attitude toward experience, engineers possess another, artists possess a third, mathematicians possess a fourth. Each deals largely with the same experience, yet each isolates and selects certain aspects of this common experience and judges it according to his own light. All these various aspects are equally real, and the judgments dealing with each aspect, in so far as they result in co-ordinated knowledge, are equally true. The engineer can not say of the artist that his judgments are bad, because their results do not "gee" with the engineer's presuppositions, nor can the scientist claim all truth as particularly his because the truths of other men's worlds are not the truths of his world.

I think that ignorance of or failure to realize the importance of these facts is at the basis of much of the inadequate and mistaken criticisms that have been made both by architects and engineers, one of the other. In some cases there sems to be on both sides a failure to recognize the meaning and intent of activity. The architect "has it in" for the engineer, so to speak, because the engineer does not appreciate the importance of meeting the conditions that the design imposes, while, on the other hand, the engineer "cusses out" the architect for interfering with the working out of his pet formula for efficiency. The cause of this state of affairs is due largely to an unfortunate over-specialization in education. But the education of the architect is necessarily somewhat broader than that of the engineer and his "fund of knowledge" is usually of sufficient scope to enable him to understand the means whereby the engineer arrives at his conclusion, whereas to the engineer there is usually something so inexact and "unreal" about art that he is prone to assume offhand that the æsthetic qualities of the design are of relatively little utility; or if the engineer does possess any artistic appreciation of the value of beauty he often tries to formulate his æsthetic judgments in the same way that his professional judgments are developed. In other words, he tries to reduce the facts of the æsthetic world to a system of scientific truths. The result is quite as logical as an attempt to organize the facts of the scientific world by the method of the æsthetic judgment. Of course we do not mean by this that the development and meaning of art and the æsthetic consciousness can not be made the subjects of rigorous analysis. But there is every difference possible between describing the processes of art in definite laws, and evaluating the results of the operations of these laws. To attempt to define one in terms of the other is to violate a fundamental canon of logic.

The necessary broadness of the architect's training sometimes places him in a position where he can judge the relative importance of the various factors in the construction of a building, whereas often the engineer is only able to realize the importance of what he himself desires to do. This has resulted in a disposition on the part of the architect to criticize where sometimes his criticism is unjust. A further result of this situation is that the co-operation of the engineer has been forced upon the architect rather than that the assistance of the engineer has been accepted as an unquestioned necessity.

Any behavior on the part of the engineer that tends to widen rather than heal this breach is unfortunate, and I propose to devote the remainder of this paper to pointing out certain mistakes in criticism which have been made by those who stand as representing the profession of illuminating engineers.

The situation, as I see it, is this: The illuminating engineer is seeking the opportunity to apply scientific principles to artificial illumination. He claims, and his claim is doubtless just, that since the old empirical methods of heating, sanitation and structural design have been reduced to general wide principles applicable to all cases, the same methods should be employed in designing lighting arrangements. He must remember, however, that in almost every case the heating and the structural engineer do not attempt to dictate to the architect how his building should be designed in order that their apparatus may be as economical and as inexpensive as possible. On the contrary, these experts take the plans as they come and lay out their work to fit the building as designed, except in rare cases where the design is such that the conditions can not be met without exorbitant expense; in which case there is usually found some solution satisfactory to both parties. The heating expert does not demand that iron-pipe coils shall be used in every case simply because iron pipe is the most efficient radiating surface known, nor does he demand that radiators shall be located only thus and so, and that they shall never be concealed because concealing them hides their true nature and lowers their efficiency between twenty-five and thirty per cent. Furthermore, he agrees with the architect that radiators and registers are at the best unsightly and should be made as inconspicuous as is possible, or else their design should be such that they will, as far as posible, tone in with the environment and become in appearance at least a part of the architectural treatment.

The structural engineer does not insist that false steel work shall never be used solely for architectural effects, or purely for supporting decorations, nor does he attempt to criticize the architect for doing all he can to hide his essentially mechanical structure. Neither does he say to the architect that he, the architect, does not know his business because he does not make his design illustrate the method of construction. On the contrary he admits that such things form no part of his business, and if he thinks of it at all, he probably admits that the architect knows what he wants and knows how to obtain it. The illuminating engineer, on the other hand, has taken upon himself, officially at least, the duties of a general architectural critic. In which he may be justified if he feels that way, and considers himself fitted to undertake the task. It seems, however, that he would exhibit better judgment if he presented himself as a critic under the proper auspices. It is a little hard to expect a man to co-operate with you if you slap his face at every opportunity. Furthermore, it seems to be the duty of the critic to appreciate and evaluate the object of his criticism from the viewpoint of the social group to which the individual belongs who created it. It is as senseless to criticize a lighting fixture solely on the basis of its qualities as a light-giving source, as it would be to criticize a building solely as a means of furnishing shelter. The lighting fixture has to give light, it is true, and also it is primarily a *lighting* fixture; but that is not all it is by any means. From the designer's viewpoint it must possess his conception of beauty and he is often quite at a loss to find some way of giving even some semblance of beauty to the very mechanical requirements that the scientist has imposed upon him.

There seems to be a prevalent idea that true criticism is destructive and not constructive. This assumption, however, fails to properly account for the attitude from which the criticism is made. Criticism must be founded upon some basis of knowledge, and it seems impossible that criticism is not a matter of comparison between what is and the ideal construction of what ought to be. To know what is wrong it seems that the critic must, *ipso facto*, know what is right, and if one assumes the duty of critic he must be prepared either to present his reasons or to be completely misunderstood. Nor is criticism a mere cataloguing of faults, for the critic, *qua* critic, assumes a position which he thinks is higher and more thoroughgoing than the position of that which he criticizes. If he is an architectural critic he assumes that he knows more about the meaning and intent of architecture than the architect himself. But the knowledge on which his critical judgment is formed must be architectural knowledge, and not mere knowledge of the history and development of the forms of construction used in architecture. If he thinks that architecture is principally a matter of construction, then he is wofully in error. As a matter of fact, in architecture the emphasis is always on the form rather than on its construction.

One may agree substantially with a theory of æsthetics based upon the development and meaning of the objective aspect of art. But when this theory is used as a basis for criticism of the solely subjective quality of beauty it is time to call a halt. No amount of study as to how things have come to be as they are can tell us altogether why we consider them beautiful or not. The *how* of things is probably far more dependent on the *why* than we are at first blush disposed to imagine.

The engineer is fully within his rights in criticizing objects from his viewpoint; but he should not criticize them for meeting some other requirements at the same time. He should appreciate the fact that the relative importance of requirements placed upon the object from viewpoints other than his may require and make necessary some modification of his own demands.

If the illuminating engineer criticized lighting fixtures only, and only as fulfilling or not fulfilling engineering requirements, the architect would have no complaint to make. But the engineer as engineer has been emphatic in his opinion as to the artistic value of many lighting installations, and, not satisfied with this, he has extended his criticisms to architectural treatment in general.

We find his printed opinion that certain works of some of our most famous architects are monstrosities, and others are in bad taste; that the modern architect is a mere copyist and compiler. We are told that the famous Hall of Mirrors in the Palace of Versailles is archaic in comparison with many a café along "The Great White Way"—that, since diamonds are always in good form (!) therefore, the faceted or prismatic glass pendent is equally beautiful and appropriate, no matter what particular period the furnishings or decorations may be in. Oh, shade of John Stuart Mill; Oh, memories of Canterbury! We hear that fixture designers often make the mistake of considering themselves artists, and that since the lamps and their accessories weigh be a few pounds, it is senseless to support them by a structure that in itself weighs many times more.

I do not mean to say that there may not be very good reasons for these, and many similar statements, for the percentage of men engaged in the architectural profession who are little fitted to cope with their responsibilities is probably not very different from the relative number of engineers in a similar position.

Concluding these remarks, is it any wonder that instead of accepting the illuminating engineer at his real worth, the architect says that he does not know what he is talking about? The attitude that the illuminating engineer seems to have taken has undoubtedly retarded the development of the profession and it will continue to do so for some time to come.

The Position of Electric Lighting in England.

By Albert H. Bridge.

PERHAPS at no previous period of the electric lighting industry have engineers been in the midst of such changes and uncertainties as they are at the present time, yet notwithstanding this circumstance there is a very decided ring of optimism in the remarks of those who attempt to foretell the future.

It has been recognized that gas engineers have already passed through experiences very similar to those of the electric lighting engineer and manager to-day—indeed, are still so passing. A very striking speech to this effect was delivered only a few days ago at the meeting of perhaps the largest gas supply authorities in England, and because the writer believes it to be of interest to electrical readers he quotes it below. It will be observed that with only a very slight variation in one or two particulars it represents the position of electrical lighting as accurately as it does that of gas illumination:

"The diminished sale was fully accounted for by climatic conditions, while the substitution of new lamps for old, of methods of burning which were increasingly economical from year to year, had added to the volume of light while enormously reducing the quantity of gas needed to produce it. One comparatively small railway station had reduced its consumption in this way by 3,000,000 cubic feet, and a city warehouse by very nearly the same amount, and these were only types of thousands throughout the company's district. They welcomed every improvement in this direction, but the immediate effect was to curtail the company's business. The simple inverted incandescent burners gave a light eight times better than good flat-flame burners, or in other words the same light could now be obtained from 1,000 cubic feet which would have required 8,000 a few years ago. With gas used at high pressure the increase was not eight times, but twenty times."

One of our illuminating experts, Leon Gaster, has gone so far as to suggest the idea that the severity of the competition between gas and electricity might be eased, or put an end to altogether, by the adoption of some mutual limitation of spheres of work. There is something Utopian in the idea; no one can say that any prospect of such an arrangement has appeared on the horizon, and few things seem to the writer less within the realm of probability. In the midst of metal filament-lamp prophesies and hopes, however, it were unwise to attempt to indicate what the effects of the most recent electrical advance may be even upon gas authorities in the course of a few years. British gas interests have developed a fighting spirit of enterprise which they did not possess in presence of a weaker rival and electrical interests are gradually becoming more enterprising too, but their desire is to hold the hand until they see which way the metal-filament cat jumps in their stations.

At St. Pancras the electricity department recently stated that the one thing that stood in the way of the small consumer was the cost of wiring and fitting. Some students of the situation urge the sanctioning of cheaper and more simplified wiring systems, a greater freedom from onerous restrictions, and some even go so far as to advocate free wiring of all consumers' premises by the undertakers. In England, where gas authorities have been so long at work, enabling them to secure so firm a hold upon the small consumer, it is, of course, imperative that it must be made as easy and cheap to change over as reasonable safety will permit. The extreme competition among electrical contracting firms is doing much to keep down the price, and to raise the indignation of organized contractors, and it may be bringing down the quality of the work installed.

Many of our electric lighting authorities have but touched the fringe of the business so far as the private lighting small consumer is concerned. A number of them have conducted experiments to watch the value of supply to small property. One of the latest steps in this direction is announced from Swansea, where some workmen's dwellings which are being built on the hollow-concrete-block plan are being wired, giving the tenants the option of slot meters, calibrated for six pence per unit. Some other authorities, who have incurred outlays of a somewhat similar kind, are being hauled over the coals by critics because the incoming tenants in the small property so wired have not thought it worth while to avail themselves of the supply at the price per unit charged, in spite of the fact that the wires and lamps are in position awaiting their use.

How far publicity campaigns can be relied upon for bringing in new consumers of the smaller class is a very questionable matter. Indeed, aggressive campaigns of this kind are not welcomed in England, either by lighting authorities or by lighting consumers. There is a more promising scope for them just at present in the power field, but even there the Britisher is a delicate subject who requires skilful, diplomatic handling. He is not to be netted by any kind of literature that tells him that he is an ignoramus or a fool, or that in sticking to old methods he is doing foolishly. A fool he may be, and may know it, too, but he is the more likely to continue foolishly if he be told that he is so by the man who is seeking to profit by his turning over a new leaf.

The coming of the metal-filament lamp, however, gives one of the best chances for publicity pamphleteering, for it is by some such means that the pounds, shillings and pence side of this lamp is going to be fully and speedily appreciated by the present small consumer of gas. Some central station men have shown no overweening anxiety to boom metal lamps, for obvious reasons, but none of them would favor a continuance of that policy for long. If the new lamps are going to reduce the cost of electric lighting to the small consumer so that he can adopt it without an increase in his quarterly bill, it can not fail to bring about an enormous amount of additional mains-laying and house-service work, for few English lighting authorities have more than touched the fringe of the business that he represents. Very large numbers of streets in which mains are not yet laid comprise, for the greater part, small-class property where gas-pipes and fittings are installed, where a gas stove is in vogue for cooking purposes, and where, if electricity were adopted for lighting, the gas stove would still be required, as electric heating and cooking are regarded as a luxury.

With this class of consumer it is almost solely a matter of pounds, shillings and pence; convenience, cleanliness, greater healthiness and all that are in many cases matters that, short-sightedly, of course, they do not care a brass farthing about. As to the standard of illumination being raised, they have the incandescent gas mantle and there is no good in blinking the fact that it seems to answer their purpose, so that it must be more the argument of cost than any other that will appeal to them.

Only a comparatively small proportion of these people are the owners of the houses in which they live and they will not run to the cost of installing electric light into premises which, either perforce or by choice, they may vacate in a very short time. So the landlord is frequently the person to bring persuasive pressure upon. But apart from the cost of installation, which is a very considerable obstacle, there is that quarterly account which is a far more impressive difficulty.

The foregoing comments relate to property which has stood for from twenty to forty years or more. To-day builders of a great deal of new property are wise enough to wire straight away, so that the tenant is not concerned with the cost of installation; the gas stove is hired from the gas company. The electrical contractor gets a hint that new buildings are to be erected, and he is on the scent if the premises are to be reasonably near to the supply mains; if the builder or architect happen to be undecided as to illuminating arrangements he is compelled to give full thought to electricity by the attentions received from the aforesaid contractor. No doubt many a new electricity consumer is being secured in this way.

It is becoming patent that it is imperatively necessary that there must be the utmost simplification of charges and supply arrangements to help in the forward movement, as W. M. Mordey, the president of the Institution of Electrical Engineers, has lately remarked. At Marylebone some very plain advice has been given concerning the necessity for exercising great care at the present time lest indiscreet changes in the matter of charges for energy should disturb relations with existing consumers. The fact is that while engineers are awaiting the effect of the use of the new lamps they can not afford to lose a single customer. Systems which are dependent mainly—or to any very large extent—upon lighting, are reckoning upon a decreased rate of increase in units sold, and some will be satisfied if there is not an actual decrease in output, but the full effect will not be felt all at once, and by the time it is making any very deep impression the existence of the "wire" lamps and their economy will have become more common knowledge among potential smaller consumers, while we may also hope that the initial cost of the lamps will fall so as to give a compensating impetus.

The lamp makers are proceeding with their arrangements for the manufacture of the new lamps on a large scale in England, but until the completion of factory equipment for this purpose large numbers are being imported from the Continent. The lamp makers are, of course, displaying considerable energy in pushing the sale, and the testimonials that they have received and are publishing from consumers, are eloquent concerning the economy in their bills for energy. In one case a consumer states that in his premises he is doing for £16 per quarter what formerly cost him £56; and numerous others produce returns showing an actual economy of fifty per cent in their payments, with a superior illuminating effect. There may be exceptional cases, such as one the writer learned of recently, where the lighting cost comes out at a higher figure, but other circumstances than the lamp itself must have been to blame, although complaints as to breakage are pretty frequent. Their extra liability to breakage in transit, perhaps due to inefficient packing, is also occasionally referred to, but these can have little force against the tide that is beginning to flow in metal lamp favor.

One of the outstanding features of British electric lighting business at the present time is the slackness of orders for new generating plant. Very few new public supply systems have been set up during the last year or two, for reasons that need not here be stated, and the engineers of some of the existing installations are nervously holding their hands in the matter of extensions to plant. It was recently stated at Hull that before making particular advance of this description the corporation awaited experience in regard to the effect of the new lamps. It is safe to say that many other engineers are seeking guidance in the same way. Mr. Talbot, in his presidential address to the Municipal Electrical Association a few months ago, remarked that the electrical plant supply would feel the effect, and he is proving to be correct. But the municipal authorities and companies who sell electricity are also feeling the effect upon their finances. Already the price of electricity has been forced down to too low a figure for reasonable profit to be earned upon its sale, and reduced consumption has in some places led to suggestions for raising the charges to the consumer who uses the new lamps. This course meets with little approval. Some authorities will be helped this year to bear the loss of revenue by the reduced cost of their coal bills, which last year were exceptionally heavy, and when comparisons have to be made this factor will require attention. The attitude of the investor who has put his money into electric lighting companies seems to be one best described as suspicious hesitation. The new lamps can not be an immediate dividend-earner, so they do not lend strength to market prices of shares; they may raise values in years to come, but it is only the shareholder who means to hold on who cares much about the future. It had been thought that after so many blows received in recent years electric lighting investments were due to take an upward turn, but it seems that it is this nervousness regarding the metal lamps that stays the movement. So that the financial position of electric lighting business in England just now, whether municipal or private, is not all that one could desire. Municipalities in some towns have become weary of carrying an electric lighting undertaking round their necks, and are inclined to receive affectionately the financier who makes an offer from a company. One of the most amusing and instructive commentaries that could be passed upon municipal electrical enterprise, and its changing moods and fancies because of changing councillors, is recorded at Bath. Here many years ago a company obtained powers and supplied the town, but it was everlastingly heckled and persecuted by the corporation until at last it sold to the latter body. It has had its run, with the city rates carrying the burden, and has just entered into contracts with private parties, who will buy the undertaking and work it through a company!

Reverting to the question of simplification of charging systems, it is clear that the maximum-demand system is going more and more out of favor. It is out of favor with the consumer because what he wants is something that he can understand without an effort, and a flat rate, however inequitable it may be thought in some cases, seems to give him less room for harboring a suspicion that he is being "done." It is out of favor with the engineer because so much depends upon his being able to satisfy his consumer. Some engineers are advocating the "contract-demand" system, one of whose points would be the equalization of quarterly bills—which might or might not avoid complaints. But space does not permit of a disquisition on charging in this article—it is sufficient to indicate that the whole subject is in process of development.

One of the satisfactory effects of the lamps so far has been the increased attention that has been devoted to isolated installations for smaller country houses, hotels, and so forth, on account of the lessened cost of plants consequent upon the increased illuminating power from a given energy consumption.

A matter in connection with interior illumination that has received more attention on your side of the Atlantic than on this is the part that may be played by illuminating engineers in the improvement of existing installations by effecting a better distribution of a consumer's lamps, and so on. Undoubtedly there is a good deal of useful work to be done in this direction, reducing waste and increasing satisfaction with electricity as a lighting agent, but there are wanting indications of a burning anxiety on the part of owners to engage a specialist of this class.

Progress is now being made very satisfactorily with electricity for street lighting and open spaces generally. The effects of the improvements introduced by the inventor and the lamp maker are very plainly apparent in this department. The innumerable types of flame arc lamps, the Nernst and tungsten lamps, are aiding the electrical engineer in making an advance, and an examination of the most recently compiled statistics shows that these are all having a pretty extensive trial in different cities. We do not go in for many thousands of arc lamps in a town yet, as you do, but a number of small places count their Nernst and flame lamps by some hundreds, while the metal-filament lamps are being very extensively employed for experimental purposes, and if they pass through the ordeal well, public electric lighting in England will advance far more rapidly than it has done. Engineers are, of course, feeling their way in the matter at present. At Colchester, for instance, Nernst lamps are being replaced by Osrams as street lamp renewals become necessary. At Brighton some hundreds of street lamps have been changed over to metal filaments.

By far the finest object lesson that the public has ever had in this country in illumination systems is that to be seen at the Franco-British Exhibition in London. Both gas and electricity are well represented in the lighting of different parts of the grounds—the court of honor has a fine electrical display by arc lamps, and the electric illuminating effects generally are making a good impression upon the public mind. Then inside the machinery hall model houses fitted up respectively by the gas and electric lighting authorities are to be found, and the visitor has an admirable opportunity of comparing the merits of the two systems.

The Illuminating Engineer.

By Albert J. Marshall, Chief Engineer, Bureau of Illuminating Engineering.

THE illuminating engineer and the principles which he is advancing are receiving, at this time, more of the careful thought and attention of architects, engineers, central station and gas men than ever before. This recognition has been brought about through the fact that the competent illuminating engineer has been able to demonstrate that it is within his ability to predetermine with much accuracy the resultant illumination from any artificial lighting installation, and at the same time produce an effect as a whole pleasing to the eye. Many of those people whose business it is to specify the use of artificial light, in its various forms, are now beginning to appreciate the fact that through the medium of good illuminating engineering principles, desirable results may be obtained, obviating almost entirely the probability of failure not uncommon where the old hit or miss, or trust-to-Providence principles are in vogue.

It is only recently that the average person whose business it was to specify the use of artificial light gave little or no thought to the value or need of such services as the competent illuminating engineer could offer. But those people who did make use of such services obtained such results that it practically compelled reluctant coworkers to acknowledge that the illuminating engineer *did* have something of value to offer and that his services or ideas in many classes of work were practically indispensable.

There were many, and there remain quite a few, people who felt that it was, and is, unnecessary to consult with a recognized authority on illuminating engineering to make use of artificial light. The large percentage of this class are persons who have been "handling" lighting problems in a hit or miss or trust-to-Providence manner for a number of years, and they have become so accustomed to using light in this manner that they have come to consider it something which requires no special skill or marked ability to intelligently make use of same. These people, feeling that light is not tangible, regard it much in the same manner as Little Eva did her existence—it just happened, and is not subject to control. To this class of people the retaining fees of the illuminating engineer are considered an unwarranted expense.

Another class of people who have been rather skeptical, but who, it has been found are rather easier to convince, are those who, in making use of artificial light, have realized that it was possible, in some manner of other, to approximate what a light source, when installed under various conditions, would do. This class often made use of certain rough formulas (based, however, on scientific data) in their work, which sometimes they were willing to discard when newer and better formulas were brought to their attention. One difficulty, however, with this class of people is that after they accept a formula they apply it without variation to all manner of installations coming under a general classification. Almost all formulas used by the illuminating engineer to-day are subject to variation, depending on conditions, and that variation is to be determined by the general experience and ability of the engineer. Therefore, any one using such formulas without taking into consideration necessary variations find that the results vary greatly, which, of course, is not good engineering. However, the people who do make use of such formulas as have been given to the public quite recently by competent illuminating engineers, are much surer of success than their coworkers, who still rely on the old hit or miss principles.

There is still another class of people who make use of artificial light, and who, apparently, use neither of the methods employed by the two. I refer to that class of people who in using artificial light subordinate almost everything to æsthetic ideas. It is reasonably safe to state that in many instances where light is used the utilitarian as well as the æsthetic should be given consideration. One seldom sees a lighting system where it would not be possible without sacrificing beauty to utilize some of the light to produce useful and desirable illumination. In other words, one seldom sees a lighting installation, unless it is purely decorative, wherein the utilitarian should be entirely subordinated to the esthetic, or *vice versa.*

This naturally leads up to the point of who must decide when the question arises whether the utilitarian or æsthetic should receive the greatest consideration; and who, might I ask, is better qualified to answer such a question than a competent illuminating engineer.

It is but recently that a few scientific men began to realize that artificial light was being used in a most wasteful manner. Realizing this condition of affairs, they began to look about for a remedy and it was principally through the application of scientific principles that the remedy was first discovered. It was the technical man, chiefly the electrical enginer, who began to make experiments in order to determine what might be done in order to eliminate this waste of artificial light; and he, naturally, because of his education and training, made use of scientific principles in attaining the desired end.

In fact, the engineer at that time gave little or no thought to anything other than the purely scientific features of the case. This I think, we can readily understand, was natural when we consider the vast improvements that the engineer saw could be made through this medium. The engineer, essentially of technical and scientific mind, up to this time had had no cause or reason to make a study of æsthetic principles, inasmuch as he had never had occasion to apply such principles to his work. As it was the engineer who first appreciated what could be accomplished by the proper use of artificial light, new systems and methods of use suggested by him were strongly impregnated with his views, his ideas. These new methods and ideas that the illuminating engineer was offering and putting into actual use were applied at first, principally, to so-called commercial lighting installations, wherein the utilitarian side was of prime importance. After a number of such installations were made it was noted that improvements on the side of economy were showing up to such advantage that the same principles were then tried out in classes of service wherein the utilitarian was *not* of such great importance. In some instances these principles were made use of by people who did not have the training or natural taste to fully appreciate the æsthetic, the result being that while the installation from an economical point of view was almost entirely satisfactory there was something to be desired in the effect as a whole.

About this time users of artificial light in work wherein other than the purely utilitarian was of first consideration, came to the fore with the general statement that the scientific mind was unable to fully appreciate the beauty and harmony that work of this nature demanded; that it was all right for the illuminating engineer to handle lighting problems where the utilitarian was the main consideration, but when it came to specifying lighting systems for such places as churches, theatres and public buildings the illuminating engineer should recognize his inability and permit those with a highly trained artistic sense to take charge.

The outcome of this controversy was that men who could and did appreciate the ultimate sphere which the competent illuminating engineer would eventually reach, began to study this new science and art from all points of view, so that they would fully appreciate not only the utilitarian and æsthetic, but the psychological as well. There being no schools or colleges where one could go to learn the principles and applications of this new art and science, it was necessary for these men to supplement their already wide experience with keen observation and close application to the study of all theories presented to assimilate the really desirable knowledge necessary for this new work. He must be able to appreciate what is meant by simplicity, beauty and harmony; to be able to see through the eyes of the architect and to so work as to assist the architect in accomplishing the most desirable end; to understand the eye, for if the eye is not given due consideration work done will be for naught.

The illuminating engineer of to-day, and I speak of that type of engineer who is competent to discuss intelligently illuminating engineering principles in all its many phases, because he has made a study of the work, is here to stay because he is necessary to success in the use of artificial light. This type of engineer is not merely a man of figures, but one who can and does cause beauty to be reflected from his ideas.

The illuminating engineer, generally speaking, has got to look to the architect for the bulk of his work and, realizing this, it is necessary to convince the architect that he is capable of carrying out any and all work which the architect may place in his hands. It has been an up-hill fight to convince the average architect that the services of a competent illuminating engineer are desirable, and often indispensable in many classes of work, and it is most gratifying to note that there are to-day architects of recognized ability who have given the illuminating engineer a chance to demonstrate his value and the results which were thus obtained warrant other architects taking up the ideas which the illuminating engineer can suggest.

I do not know of a single instance where the architect, when he consulted with a competent illuminating engineer, had reason to regret it. Unquestionably the day is rapidly approaching when the illuminating engineer will be firmly established and those who appreciate his value will gain over their reluctant brethren.

The Carbon Flaming Arc.

By Thomas Spencer, Chief Engineer, Helios Manufacturing Company.

ALTHOUGH the term luminous arc has been applied to a much larger field than formerly, including, as it now does, lamps in which the electrodes are of other substances than carbon, and in which the light is given from the flame rather than from an incandescent crater, the term flaming arc seems to be applied only to the earlier form in which the electrodes are carbon impregnated with the salts of alkaline earths.

This form, which is the subject of this article, has now been a commercial possibility for something like five years and has been upon the American market for a little more than two years. Abroad it has made great progress and lamps of this character can be seen burning in great numbers in all of the large cities, but here the introduction has been comparatively slow. It is true that a few can be seen on the streets of our principal cities, used mostly for advertising purposes, but still the number of lamps used is very small compared with what you would expect for a source of illumination whose efficiency is so much higher than any other.

The principal reason for this, in my mind, is the short life of the carbons.

The complete replacement of the open arc with us, by the enclosed, has so accustomed our people to an arc lamp which has a long life that one which requires frequent trimming is not attractive, no matter what its other good qualities are.

Abroad this does not apply as the enclosed type of lamp has not obtained the footing it has with us.

There is another reason perhaps which has contributed to lessen the rapidity of their introduction and that is that the lamps which were first brought to this country were of a type known as the clockwork pattern. This form is looked upon here as much too delicate to long stand the hard service to which arc lamps are subjected, but no doubt the short life of the electrodes is considered the greater drawback.

In some of the early lamps, the light-giving salts were mixed through the body of the carbon and in large quantities. This was found to give a great amount of light, but unfortunately when the lamp was turned off it would not light again on account of the insulating slag that was formed upon the ends of the carbons. To overcome this an attempt was made to break off this slag by means of a mechanical device worked by a magnet, but this was not very successful.

Then an old form of lamp in which were two carbons pointing downward at an angle to each other was tried, the supposition being that the slag would drop off as fast as it was formed, leaving the points of the carbons clean. Although this was a great improvement over the carbons placed one above the other, the difficulty still continued and it was not until after the German carbon makers had taken up the manufacture of this type of carbon and had discarded the form in which the light-giving salts were mixed throughout the body of the carbon and had substituted one with a core containing the light-giving salts that this trouble began to disappear. It was soon found, though, that this type required the carbon to be the smallest possible diameter to secure steady burning, and this small diameter, of course, as it will easily be seen, reduced the time of burning of a pair of carbons of a given length, so, to obtain even a practical life, the carbons had to be made of an unusual length and, of course, with a corresponding increase in the length of the lamp.

Another difficulty which the small diameter of the carbons introduced was the large variation in resistance which they caused in series with the arc which very much interfered with the regulation of the lamp.

To remedy this, copper plating of the carbons was first tried, but this did not seem to meet the conditions. The solution was finally found in the introduction, either in the core or in a special opening running the whole length of the carbon, of a metallic wire which in some cases was zinc and in others brass, depending upon the makers. In spite of all of these improvements the objection still remained of a long, delicate carbon. To remedy this a great many inventors have tried their hand at what are known as magazine lamps; *i. e.*, lamps in which a number of carbons are placed in a magazine, only one carbon burning at a time. As soon as it is consumed another takes its place automatically from the magazine, and this continues until all the carbons in the magazine are consumed. Quite a number of lamps of this character are in operation abroad, but on account of their necessarily complicated structure it is evident they are bound to be troublesome in operation.

Another set of inventors have tried burning a number of pairs of carbons in parallel, the arc shifting from one pair to the other as they burn away. While this is much simpler than the magazine form it involves considerable difficulty in the control of the arc by the blow magnets, which control is absolutely necessary to produce steady burning.

If, instead of a number of carbons, only two pairs are used, this trouble is overcome and, in my opinion, the most practical solution of the life question is obtained, as with two pairs of carbons of reasonable length a life of between twenty-five and thirty hours can be obtained with a lamp whose length is only a few inches longer than the average enclosed lamp.

Our friends across the sea, from whom we received our ideas of the flaming arc lamp, realized that their solution of the problem, as far as the lamp was concerned, was rather a complicated one, but they think there is no way of accomplishing the results other than by the so-called clock-work mechanism.

It is quite true that several types have been developed which do not use the clock-work form, the feeding of the lamp being accomplished by letting one carbon rest upon a support at its burning end, the carbon feeding down as it burns away by gravity, carrying with it the other carbon to which it is attached mechanically. This form of lamp has taken a great many shapes, according to the ideas of the inventors. In a number of cases special forms of carbons are used, while in others the simple round carbon is retained. This lamp has a number of good features, the principal one being that it can be operated in series without a shunt coil and, of course, this principle leads to great simplicity in construction. Unfortunately experience has proven that the burning of the carbons is much less regular and reliable than when the carbons are burned free with no support. This is even the case with those lamps using the special forms of carbons, and the use of any special carbon is a serious objection in itself. From what I have said it would therefore seem that there is some middle ground in the construction of a flaming arc lamp between the clock-work lamps of the Germans and the so-called gravity-feed lamp which we have just described which will be the final form which this type of lamp will assume.

Considering the improvements made, which I have pointed out, it would seem that there should be a large field in this country for this form of illumination, as there is no question that the volume of light obtained for the energy expended is the highest obtainable. The golden yellow color, the form usually used, has proven extremely pleasant to those who are compelled to work under such an illuminant and, besides this, the color is particularly suitable for illuminating such places as are dull from dirt and soot, as more light is reflected from such surfaces with this color than with ordinary white light.

I feel that when these points are fully appreciated by the American people that the flaming arc lamp will be much more generally used, even more than it is abroad.

A New Field for the Electric Sign.

By Benjamin Wall.

WHILE it is pretty well understood that many progressive business men of to-day do not consider an establishment complete without a suitable electric sign burning either a name or a business into the mind of the public every night the store is open, it is not so well known that there are numerous electric signs now being used in lower Manhattan as "business-getters" that burn all day from the opening until the closing of the store.

The streets of New York are somewhat narrow, but the same statement applies to a number of other cities of importance in this country. Narrow streets with tall buildings and the resultant darkened area give the central station sign man an excellent argument when advocating the use of the electric sign for daylight advertising.

A Nassau street clothing-store proprietor uses an electric sign containing 125 eight-candle-power lamps, the sign being placed flat against the building, and although the show window beneath is brilliantly illuminated the sign burning in the daylight attracts the greatest attention and has added considerably to the business of this house since its installation.

A well-known retail drug store in lower Manhattan has for some time maintained a panel sign in front of its window. This sign is lighted from 8 A. M. until the store closes at night and is a prominent feature of the advertising display made by this firm.

In the shoe store of Frazin & Oppenheim in New York city may be seen another electric sign burning all day over an archway leading from the main store to their annex.

Another case of daylight use of the electric sign may be observed in Brooklyn. The Abraham & Straus department store has an entrance leading from the subway directly into its store, and it has installed an electric sign with the firm's name in electric letters over the doorway. This sign does double duty, as it burns all day during business hours and at night, even when the store is closed.

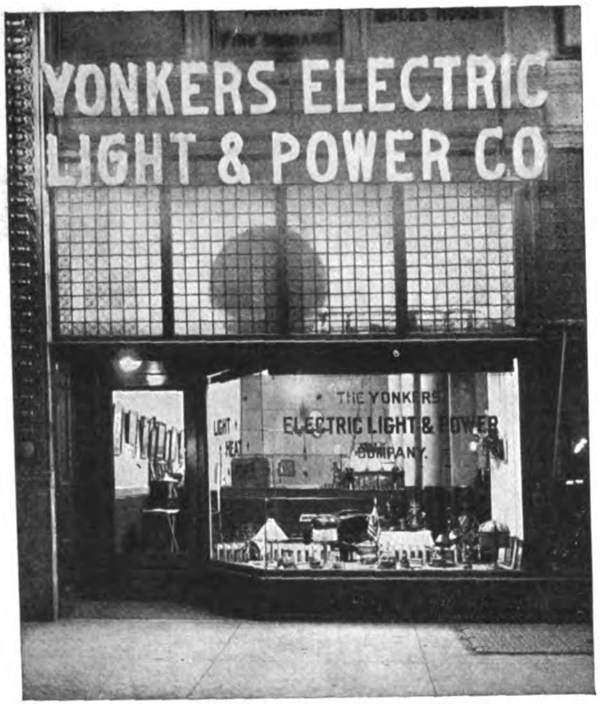
A Daylight Electric Sign.

The outside stock exchange, known as the "Curb," which holds its meetings in the open air on Broad street, south of Exchange place, in New York city, has been a cause of complaint on account of noise to the occupants of office buildings nearby. To end this trouble S. Mendel, the "dean" of the "Curb," decided to use an electric call sign. Each brokerage firm was given a number, and a blackboard, equipped with incandescent lamps under the firm's number, may be seen from both sides of Broad street. If the representative of Mendel & Company is wanted at the telephone, their number is flashed on the electric sign, and until the call is answered the number remains displayed on the electric call board.

Anent the general use of electric signs, the illustration of the first electric sign in New York city, shown herewith, is interesting. This sign was installed some twenty years ago at the spot where the so-called "Flatiron" Building now stands, at Broadway, Fifth avenue and Twenty-third street.

Part of this sign was flashed and there is an interesting little story connected with the flasher that was in use here, it being stated that instead of commutators, gears and motor now in universal use for flashing electric signs, the flasher for the first sign was operated by hand-power. Knife switches were installed for each circuit of lights and a young man employed to pull the switches until one line of letters was flashed, then he closed the switches, thus lighting the entire sign. This was done from dark until midnight every fair night and must have been a very irksome task for the "human flasher."

So confident was the Garden City Estates Company that an electric sign would prove beneficial to its business that it insisted on a clause being inserted in its lease giving it the privilege of installing an electric sign in front of the windows of its suite of offices on both sides of the building on the north end and willingly paid a higher rental for the privilege.



How One Electric Light and Power Company Takes Its Own Medicine.

Central stations throughout the country are using the electric sign more than ever, thus setting an example to the merchants of their cities, and even the gas companies are taking up the electric sign to advertise their product.

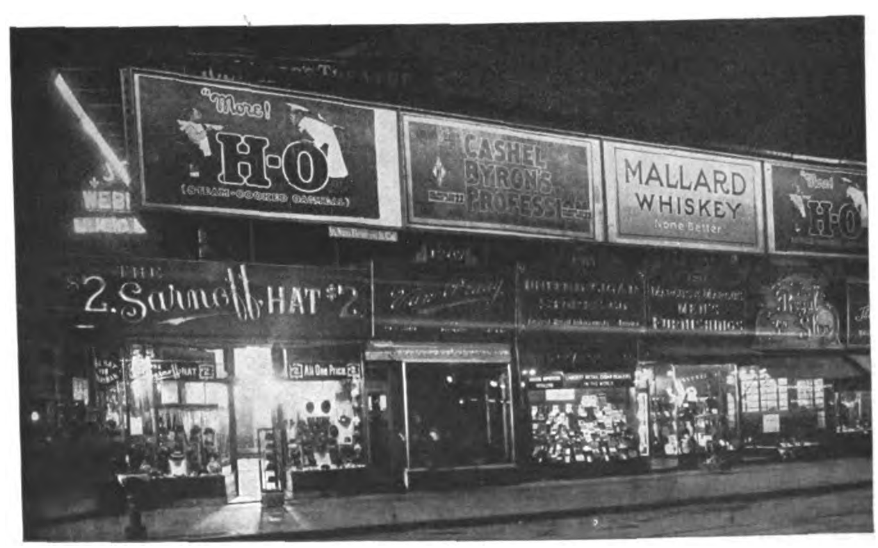
On One Hundred and Twenty-fifth street the Consolidated Gas Company has installed a large vertical electric sign reading "Cook with Gas." The Municipal Gas Company, of Albany, N. Y., has a similar electric sign in front of its office building. The Public Service Corporation of New Jersey has recently placed in front of its Passaic office building a vertical electric sign reading "Use a Gas Range." All main line trains of the Erie Railroad pass within two hundred feet of this building and the sign is read at night by thousands of passengers.

The Utica Gas and Electric Company has one of the best advertising signs in the country. On the smokestack of its power station in Utica it has installed an electric sign of the skeleton-letter type reading "Utica Gas and Electric Company." It can be read at night for several miles and is an excellent daylight sign on account of its great size.

The New York Edison Company has the honor of using the largest vertical electric sign in the world. It is built in four sections and is 100 feet high, with letters twenty-four inches high studded with electric lights. This sign, with the large electric roof signs on all four sides of the Duane street office building, gives that section of Manhattan the appearance of being on fire at night.

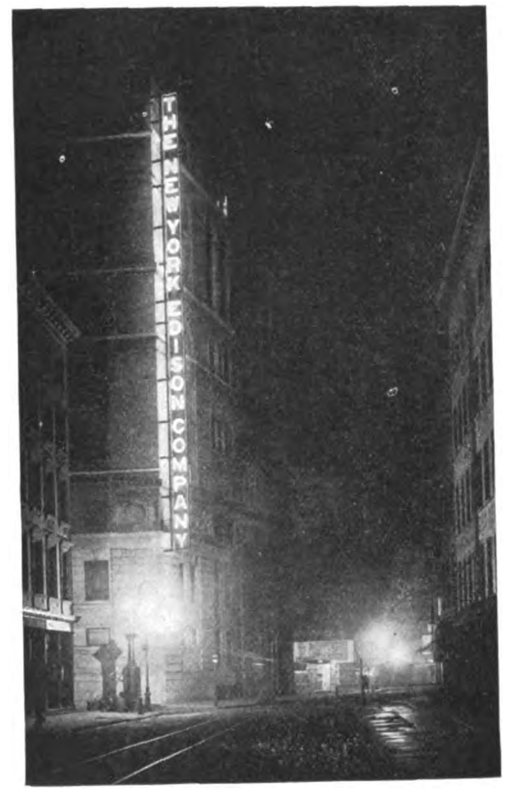
The First Electric Sign in New York City.

The Yonkers Electric Light and Power Company has installed a large electric roof sign as well as a flat box skeleton-letter sign in front of its office building. The roof sign can be seen both day and night from almost any point of the Highlands across the Hudson and from all Hudson River steamboats.



A Well-Illuminated Bill-Board.

One of the notable electric signs on the river front is that of the Heinz Pickle Company. The letters "Heinz" are fourteen feet tall and the numerals "57" are each twenty feet high by fifteen feet wide.



The Tallest Electric Sign in the World.

This sign can easily be read by day or night from Hoboken and Jersey City and from all the ferryboats plying on the Hudson River, and, like the Colgate sign in Jersey City, is a landmark of the sky line of lower Manhattan.

In Greater New York a recent ordinance has compelled the reduction in the size of sidewalk electric signs to six feet at right angles from the building. The

United Cigar Stores Company had a number of eletric signs in front of its stores that exceeded this limit and the writer visited several of these stores with the cigar company's electrician to see what could be done to so modify the signs as to bring them within the requirements of the new ordinance. It may be worth while to relate here the gist of a conversation which occurred between one of the cigar store company's managers and their electrician on one of these visits. The manager stated that he hoped his sign could be fixed speedily, adding "since that sign has been up I have done fifty dollars a week more business in this store." This was with a sign that represented an investment of about $75 for the sign and necessary service wiring.

The New York *Herald* has recently placed a V-shaped electric sign in front of its One Hundred and Twenty-fifth street branch office. The New York *Evening Post* one on the roof of its beautiful new office building in Vesey street. The New York *World, Staats Zeitung, Press, Times, American* and Brooklyn *Daily Eagle* and Brooklyn *Citizen* have all installed electric signs on their main and branch offices, and there is no question that they feel it is a profitable method of advertising.

A view of a section of bill-board reflector lighting is shown herewith. These reflectors are at the northwest corner of Broadway and Twenty-eighth street, New York city—well known as the site of Weber & Fields' theatre. The bill-boards are ten feet high and the reflectors five feet from the bill-board. For a cheap and satisfactory method of advertising by day and night nothing has yet been devised that will take the place of the electrically illuminated bill-board. Placing the lamps one foot apart (using either four-candle-power or eight-candle-power lamps) will give all the light required with reflectors at a distance of five feet to properly illuminate a ten-foot bill-board. The lamps used in this illustration are eight candle-power.

The first recorded instance of the use of tungsten lamps in sign lighting is that of the New York Edison Company, which is just installing a sign reading "Tungsten Lamps" on its branch office in West Thirty-second street, equipped with twelve-volt, twenty-five-watt tungstens, operating ten in series.

In closing, the writer considers the following account of an incident related by a manager of a central station sign department of possible interest. The customer occupied the basement of a three-story building. He ordered a panel sign from the central station, the sign to be erected over his door. To do this safely it was necessary to use guy wires which ran across the windows of the floor above. The tenant on this floor objected to this and the central station man was threatened with a cancellation of the sign contract. He was so well satisfied that the sign would benefit the customer who had ordered it that he suggested and was able to convince his customer that even if he had to rent the other floor it would be better to do so than to give up the sign. The customer was able to secure a lease of the floor above and to-day occupies the entire building, where only two years before he was able to handle all business that came his way in the basement. He has the electric sign and would not part with it under any circumstances.

Luminous Arc Lamps.

By G. N. Chamberlain.

THE luminous arc, sometimes termed magnetite arc, metallic-flame arc, has for some time been admitted by the most conservative or sceptical to be out of the experimental class. Although through the early stages of development, the system was received with scepticism by many of the leading illuminating engineers and arc-lamp manufacturers, it has long since been acknowledged as the most reliable and efficient illuminant available for outdoor services. At the annual convention, held in Chicago, May, 1908, the National Electric Light Association accepted the report of its committee of representative illuminating and central station engineers, which placed the luminous arc in a class by itself and far ahead of all the other out-door illuminants investigated.

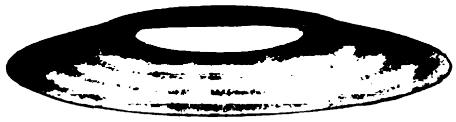


Fig. 1.—Concentric Ring Reflector.

The many points of superiority claimed for the system have been expounded in detail, both by the representatives and publications of the manufacturers, and the interesting phenomena of the luminous arc itself have been discussed at length by the technical press. A repetition of such details is therefore unnecessary as the data can be secured through the channels mentioned. Several years' commercial operation has resulted in the introduction of refinements into the series luminous system. Fig. 1 illustrates a concentric ring reflector designed for use with the series luminous arc. The superior distribution of light resulting from the use of this type of reflector in connection with the carbon arc has led to its application to the series luminous lamp. The use of the reflector, while maintaining the same lighting distance previously attained, assures an evenly diffused light and absence of shadows in the immediate vicinity of the lamp.

Fig. 2 illustrates a well-known form of copper upper electrode. The diameter of the copper has been increased from five-eighths inch to three-quarters inch and entirely enclosed with the exception of the burning ends, with one-sixteenth-inch iron casing. The use of the extra amount of copper and the prevention of the rapid oxidation of the same by the iron sheath have increased the life of the electrode to about 6,000 hours, or approximately fifty per cent. While no radical changes have been made in the design or manufacture of the lower electrode, a more uniform product and a gradual increase in life and efficiency are being obtained.

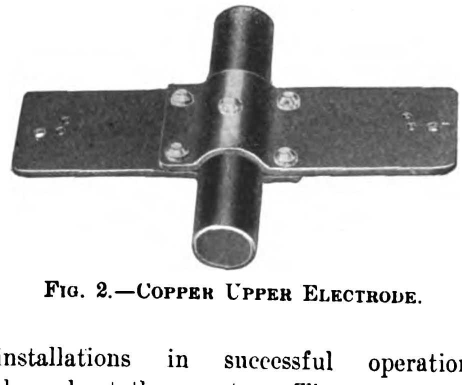

Fig. 2.—Copper Upper Electrode.

Fig. 3 represents a street lighted by luminous arcs and is one of the many installations in successful operation throughout the country. The system has not only been adopted by the smaller towns and average-sized cities, but has been accepted by the larger representative cities of the country.

The following extract from a daily paper of recent date is representative of the expression of universal approval with which the system is received:

"On Saturday evening the new electric street lamps were turned on after having received a good test and found entirely satisfactory by the superintendent and the electric light committee.

"The system that furnishes the light is the newest on the market, and its simplicity of construction and operation is apparent even to the layman.

"This new type of lamp is particularly suited to street lighting. It has a small power consumption, four amperes, at seventy-five to eighty volts, being about one-third less than the old lamps. Everybody has noticed the uniform lighting of our streets and commented thereon. There are hardly any shadows in the streets between the lights. Combined with this new lamp is the efficient transformation of alternating current into direct current by means of a mercury arc rectifier.

"Ordinary carbon electrodes are rejected in this system. To explain the operation of the lamp would be to give the reader a lot of technicalities, which are unnecessary in view of the fact that the lights work exactly as represented by the installing company, and that the people are very well pleased.

"The superintendent says that these lamps will need trimming but twenty times a year, and that the department expects to run at least 3,500 hours a year.

"Council had a number of systems to choose from, but all the members were unanimous in picking the luminous and not one has any complaint whatever to make. All over town the people are commenting on the uniformly bright lights and are expressing themselves in high terms of praise on the electric light department's acquisition."

So marked has been the success attained by the introduction of the series luminous arc, that it has naturally lead to other applications. Conditions often exist where it is prohibitive or at least undesirable to install a high-potential series circuit, but where otherwise the luminous arc would most efficiently and satisfactorily fulfil the requirements. To meet such a demand there exists a lamp suitable for maintaining a luminous arc on direct-current circuits of nominal 110 volts or multiples thereof.

Fig. 4 illustrates a type of lamp available for multiple or series-multiple operation. For single operation on 110 or 220-volt circuits the lamps are connected directly across the line, the difference between the two lamps being that of windings and adjustment.

Besides being operated singly on 220-volt circuits, two lamps may be connected in multiple-series and such connection is necessary where higher voltages only are attainable. The arc proper has all of the characteristics and advantages of the series luminous arc and the lamp is representative of the most modern arc lamp engineering practice.

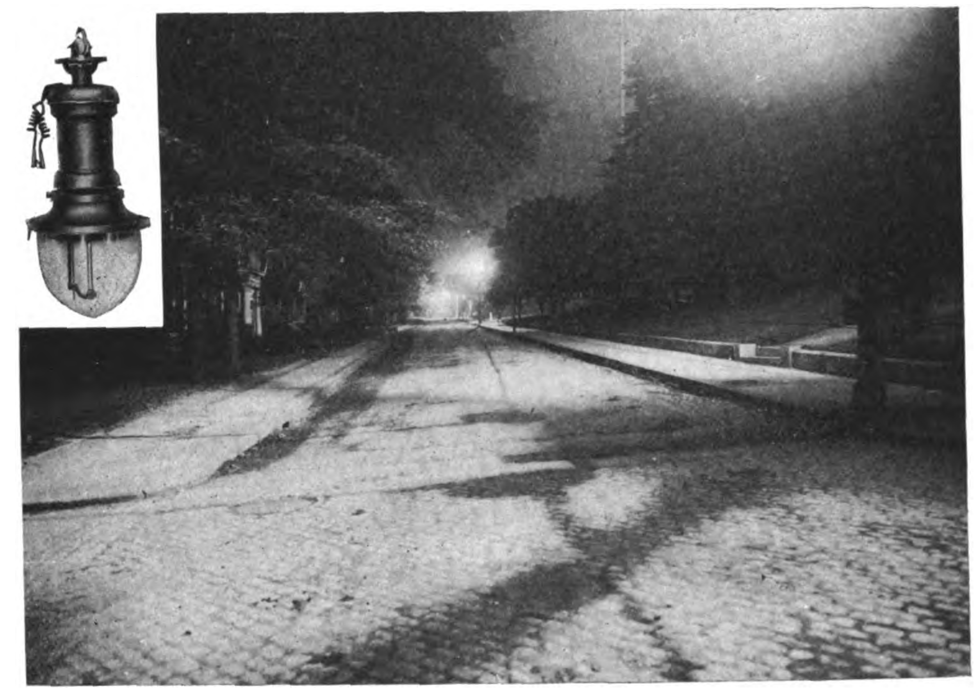

Fig. 3.—Street Lighted by Luminous Arcs. The Lamp Shown is for Series Operation.

The casing is symmetrical in construction, of pleasing appearance and so arranged as to admit of the use of the twenty-six-inch concentric diffuser, the advantages of which have long been acknowledged in connection with the distribution of light from the enclosed carbon arcs.

Fig. 4.—Luminous Arc Lamp for Multiple Operation.

This type of lamp is especially recommended for the lighting of foundries, freight yards, machine shops, train sheds, freight houses, drill halls and riding academies, or, in general, for the lighting of large areas where the fumes would not be noticeable.

The luminous arc is also found to be ideal for city street and interurban headlights. This application of the luminous arc is the result of the constantly increasing demand for a more efficient and reliable headlight than could be obtained with the enclosed carbon arc. The track illumination is very satisfactory, the headlight not only illuminating the track for a distance of 1,200 to 1,800 feet ahead of the car, but the beam is exceptionally broad. The peculiar characteristics of the luminous arc are such that by reversing the current, thereby making the copper electrode negative, the light is reduced to such an extent as to make it suitable for city service. This is readily accomplished by a reversing switch installed in the car vestibule near the motorman.

The maintenance of the enclosed arc headlight for cars has always been comparatively high on account of excessive globe breakage and resulting rapid consumption of carbons. A life of 2,000 to 3,000 hours for the positive electrode, fifty to seventy-five hours for the negative electrode, together with the absence of all enclosing globes, is readily appreciated as shown by the number of present users of the luminous arc headlights.

Another type of luminous headlight has been designed for mining locomotives, which is also available for use in localities where a heavy cast frame of small dimensions is required for protection.

The Helion Lamp.

By Professor H. C. Parker and W. G. Clark.

WHILE the difficulties encountered in the experimental investigations involved in the development of the Helion lamp have been very great, such progress has been made that we feel that commercial perfection is rapidly being approached. Early in 1907 we exhibited the first Helion filaments upon which a satisfactory life was secured. These were extremely sensitive to the slightest trace of gas in the lamp bulb, and it was difficult to exhaust the bulbs to the necessarily high vacuum. When the lamps were burned with only a slight trace of gas in the bulbs, in the course of time a cathode discharge was set up between two points of the filament near the terminals, and this invariably resulted in burning out the filament near one of the leading-in wires. This gas which caused the trouble was contained in the cement, and was very difficult to remove entirely. After experimenting with a great many cements a process of elimination finally provided one best suited to the purpose. The vacuum apparatus was also developed to the point which the characteristics of the filament demanded.

It was realized, however, that the difficulties entailed in making such a process commercial were enormous, and a series of experiments was started on the filament itself in order to reduce its sensitiveness to the presence of gas and enable the filament to be burned in a vacuum at a slightly higher pressure than that at which the cathode rays were liable to start.

A great deal of work has been done to make filaments of a uniform composition, and to standardize methods under which they were produced, so that it could be announced definitely that invariable results could be obtained. It is now a fact that a filament has been secured which is less sensitive to the presence of gas, and this is well substantiated by the demonstration of the burning of this filament with an efficiency of two and one-half to four watts per candle in the open air without any enclosing glassware whatever. Where the heat is retained by reducing the convection currents, the efficiency, of course, increases very rapidly.

The new filament differs in some characteristics from the original Helion filament, and a tabulation is now being made of many of the interesting physical properties which are being discovered.

So much success has been attained in the production of filaments of a much higher resistance than the original filaments, that we are now able to absorb either 110 or 220 volts in a single loop of moderate length and comparatively great cross-section. This filament may be maintained at bright incandescence in the air for many hours without deterioration, at a temperature approximating 1,800 degrees centigrade. When atmospheric dust is kept away from the filament there is apparently no surface change, but when particles of dust in the atmosphere come in contact with the hot filament they are fused and stick to it, so that in the course of time the filament takes on a growth, the rate at which the accumulation develops being entirely dependent upon the amount of dust which comes in contact with the filament.

A peculiar feature of the filament is that after burning a number of hours in the air there is noticed a slight progressional change in luminosity. This begins at one terminal and gradually continues around the entire length. It has been discovered that this is due to the burning out of the carbon core on which the filament is formed. As this core burns out the tube remaining is composed of pure Helion and, as the only portion of core exposed is the end within this tube, the rate of oxidation is very slow. When the carbon core is entirely burned out, the conductivity of the filament is decreased by an amount equal to the original conductivity of the carbon core. This effect can be prevented by sealing the terminals of the filament to prevent oxidation. When this is done the filament will burn in air for a great length of time.

The specific resistance of the filament is nearly fifty times that of the carbon filament, and several hundred times that of tungsten. The filament is also very hard, it being possible to scratch glass with small particles of it under the thumb nail.

When the incandescent filament is plunged in water there is apparently no effect other than a change in temperature.

One of the unexpected phenomena which have been observed when the new filaments were mounted in a high vacuum and operated at a high temperature was the coating of the globes with pure silicon, due to an intense ionization, forming a mirror deposit. This has been overcome by giving the filament a slight coating of another material which prevents this ionization from starting. Further experiments along this line are being conducted and the results are extremely promising. One of the filaments experimented with in this manner has already shown a life of more than 600 hours at a satisfactory efficiency, and is still burning with no appreciable diminution in candle-power or change in resistance.

It has been found that a Helion filament made to operate under the conditions which produce the most intense ionization can be utilized as an "Adion" in the de Forest system of wireless telephony with most satisfactory results, and experiments are now in progress to utilize the filament as a detector in wireless telegraphy and telephony.

While the development of this lamp may appear slow, it must be remembered that between each step, as progress is made, there must be a countless number of trials, life tests and experiments, and a long period of time is required to secure accurate data and ascertain the effect of each experiment. The constant effort has been to reach a point where filaments of uniform composition and resistance, and of the highest efficiency, could be produced invariably. Considerable progress has also been sacrificed in adapting the filaments and mountings to utilize standard glassware and the standard appliances and auxiliaries now used in the production of the present commercial types of carbon-filament incandescent lamps. We have now met with such success that we feel it is entirely reasonable to assume that a commercial Helion lamp will be available in the not distant future.

In addition to the standard types of lamps, experiments are progressing with a view of adapting the Helion filament to such forms as are called for in miniature lamps, tubular lamps, headlights and searchlights. A novel construction, with which considerable success has already been attained, is one in which are used four filaments in parallel, each filament connected to a single neutral point. Where each filament is of ten candle-power the lamp originally gives forty candle-power. If one of the filaments should burn out or be broken through accident, the lamp will continue to give thirty candle-power. If another filament is broken it becomes a twenty-candle-power lamp, and when but one filament remains it is still a ten-candle-power lamp. In this way the same lamp can be removed from one circuit and placed in a position where a smaller amount of light is required, thus extending its service over a very great period of time.

Flame Arc Lamps.

By W. H. Jones.

DURING the past three years many improvements have been made in the various types of illuminants, foremost among which are those pertaining to the flaming arc. Introduced into this country as an advertising novelty, it has attracted and held the attention not only of the public at large, but of the manufacturers as well.

On account of its remarkable illuminating power and the ever-increasing demand for more efficient units the flame lamp fills a long-felt want for certain classes of illumination, especially the lighting of large areas foggy with smoke or dust. As an advertising medium it has had a marked success and will continue to hold its present prominent position until supplanted by an illuminant more efficient and more pleasing in appearance.

Flame lamps of foreign manufacture were for a time the only types known, and it did not take the American manufacturer long to appreciate the inroads being made by them into his markets. Realizing the possibilities of this type of lamp and the necessity of giving the public a lamp conforming to American standards and practice, many types have been placed on the market, among which may be mentioned the G. I. flame lamp manufactured by the General Electric Company.

This lamp, shown in Fig. 1, has the same appearance as the standard line of enclosed lamps manufactured by this company under the same trade name. These lamps are extremely simple in design, rugged in construction and reliable in operation, having, instead of the usual complicated and delicate clock mechanism, chain feed and escapement common to the foreign lamps, a screw feed arrangement which comprises but few parts and which is equally as efficient.

This arrangement of the feeding mechanism is a pronounced improvement since the introduction of the flame lamp in this country, and with equal efficiency and steadiness of light gives it a distinct advantage where maximum illumination is desired. This lamp is of the converging carbon type, and so designed that the carbons are both supported in holders and are not dependent upon buttons, stops or a special rib on the carbon itself. There is nothing below the arc to obstruct the light in any way and when the lamp is in operation the whole globe appears to be a luminous sphere uniformly illuminated.

Photometric curves made in the illuminating engineering laboratory of the General Electric Company show that the light emitted is practically equal in intensity

Fig. 1.—G. I. Flame Arc Lamp.

from twenty degrees below the horizontal to the vertical position, thus permitting the lamp to be hung in a very high position and still give perfect illumination.

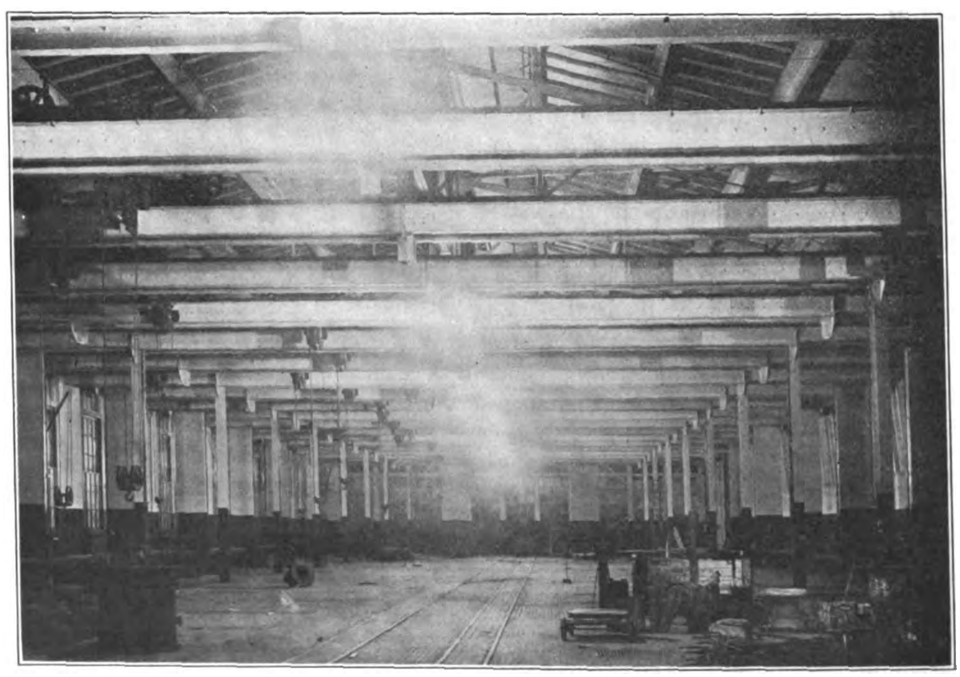

Fig. 2.—Night Photograph in Iron Foundry, Pittsfield Works of General Electric Company. Lighted by Six Twelve-Ampere G. I. Flame Arc Lamps, Run Two in Series on 110-Volt, Sixty-Cycle Circuit. The Space Lighted is 264 Feet Long by Seventy-five Feet Wide. Lamps are Spaced Thirty-five Feet Apart and Suspended Sixteen Feet from the Floor.

In view of this special advantage and the fact that these lamps have been approved by the Factory Mutual Laboratories for the Manufacturers' Mutual Fire Insurance Company, they can be recommended for illuminating machine shops, erecting shops, train sheds, ferry houses and similar places having large free areas.

Fig. 2 shows an interior view of a foundry, 264 feet long by seventy-five feet wide, illuminated by six G. I. flame lamps. These lamps are operated two in a series, on 110-volt multiple alternating-current circuits, and are adjusted for twelve amperes. They have a power-factor of seventy-five per cent, and at this value, 990 watts are consumed by each pair of lamps, or 2,970 watts for the six lamps. The total floor space illuminated is 20,670 square feet. Thus it will be seen that the actual watts per square foot in this installation is but 0.14. In order to give a comprehensive idea of the brilliancy of the illumination, which can not otherwise be given on account of lack of photometric data, the writer would call attention to the fact that he was able to read ordinary printed matter in any part of the room, and with his back toward the source of light.

The lamps mentioned above were trimmed with carbons emitting a golden-yellow light, and it should be remembered that for similar installations, or for the illumination of docks, ferries or train sheds, where the atmosphere is foggy or filled with dust, the yellow light is much more beneficial on account of its penetrating qualities and adaptability to the human eye.

Manufacturing concerns throughout the country are seriously considering the question of illumination from every viewpoint, and in many instances have changed over their entire lighting system to flame lamps. This has been made possible by the advent of the American-made flame lamps with their excellent qualities of efficiency and economy in operation, as well as their low selling price.

Although the maintenance charges are somewhat higher for the flame lamp than for other illuminants, it is rapidly increasing in popularity, a partial reason for which is given by the data set forth in the following table:

ALTERNATING CURRENT FLAME LAMP.

Amperes	12
Volts	55
Watts at terminals	500
Hemispherical candle-power	1,167
Spherical candle-power	874
Watts per hemispherical candle-power	0.428
Watts per spherical candle-power	0.572
Hours life per trim	12

Rapid Introduction of Tungstoliers.

A representative of the ELECTRICAL REVIEW a few days ago met E. J. Kulas, vice-president and general manager of the Tungstolier Company, of Cleveland, Ohio, west-bound on the Twentieth Century Limited. Mr. Kulas was very enthusiastic over the new Tungstolier units which are being marketed by his company. In response to an inquiry, Mr. Kulas stated that approximately 27,000 of these Tungstoliers, each meaning a complete fixture, shade equipment and tungsten lamps, had been marketed since the beginning of shipments in April. Over fifty salesmen are now devoting their entire time to the introduction of the Tungstoliers. These salesmen are working from nine established branch offices. Mr. Kulas added: "The future before this tungsten lighting system is far and away beyond our original conception. Within six months we expect to have 200 salesmen, working from sixteen or twenty branch offices, and we believe that the old methods of purchasing lamps, fixtures and the component parts of the lighting unit from several different companies will be changed, to a very great extent, by the sale of the complete Tungstolier unit. The Tungstolier will revolutionize electric lighting and make possible 'daylight' at an enormous saving in cost."

The Just Tungsten Lamp in America.

J. Auerbach, president of the Electrical Accessaries Company, New York city, returned recently from an extended trip to Europe, where he visited and inspected the factories producing the Just tungsten lamp.

The average life of these lamps is not less than 1,000 hours, when burned under proper conditions. The factories have made progress in their manufacturing methods, and the company is turning out at present the standard twenty-five, forty, fifty and 100-candle-power lamps for 100 to 125 volts, as well as the fifty-candle-power lamp for 200 to 250 volts. The company is also making a 200-candle-power and 400-candle-power lamp which should create quite a demand for the replacement of arc lamps, not only for interior lighting, but also for street lighting.

Mr. Auerbach is particularly enthusiastic over the special Type D lamp, in which the entire filament is supported in springs. This lamp can be burned at any angle, and the life of these lamps, he states, will be found to be just as great as the vertically burning lamp. The construction of the Type D lamp is original, and embodies some exclusive features obviating the difficulties which have been found in other types when burned at an angle. This type of lamp at present is made in twenty-five and forty-candle-power sizes.

From its inception the Just tungsten lamp has been distinguished by its neat design and compact appearance.

The Electrical Accessaries Company has arranged for large shipments to be delivered regularly, and the company carries in its New York warehouses about 100,000 lamps of the different candle-powers and voltages for immediate delivery.

The company expects to bring out shortly a line of special transformers of an entirely novel construction. The transformers will reduce a current of 100 to 125 volts or 200 to 250 volts to sixteen volts, thereby making it possible to install five, eight and sixteen-candle-power tungsten lamps. These transformers are so small that they may be readily attached to the canopy of the chandelier, placed on the wall, or applied directly to the lamp, if necessary. With this transformer it will be possible to install sixteen-watt tungsten lamps for direct use on any voltage up to 250. The loss caused by the transformer is about one watt per lamp. The transformers will be built for one, two, four or six lamps, and it is expected that the cost of lamp and transformer will not be greater than the present price of tungsten lamps.

The lamps will contain one heavy filament, giving an increased life to the lamp, and will also mean the introduction of the tungsten lamp in lower candle-powers.

A feature of considerable importance with the Just tungsten lamp lies in the fact that when the lamp is screwed in the socket every extending part of the base is insulated, thus conforming with the most recent suggestions of the Underwriters' Laboratories.

The company is arranging for the appointment of local agents in the larger cities throughout the country, and will have a number of the most prominent houses represent it in the various centres of the industry.

An Interesting Installation of Just Tungsten Lamps.

S. Gruhn & Company, 1947 Broadway, New York city, announce that on March 17 an installation was made in one of the largest billiard academies in New York city of sixty forty-candle-power and thirteen 100-candle-power Just tungsten lamps, in place of 165 sixteen-candle-power carbon-filament lamps. The company's client was formerly on a wholesale rate, guaranteeing a fixed amount per month. Just before the installation of these lamps he entered into a contract with his landlord whereby he purchased current at or about five cents per kilowatt-hour. When on the wholesale rate the bills averaged from $170 to $220 per month. With the installation of the tungsten lamps the average of the bills was cut to $28 to $45 per month. The total cost of renewals since March 17 has been $7.50.

The company states that there is no perceptible diminution in illumination and that the lamps receive pretty rough usage, being cleaned three times a week.

North Carolina Independent Telephone Association.

At the third annual meeting of the North Carolina Independent Telephone Association, which was held recently at High Point, N. C., the following officers were elected: President, W. A. Wynne, Raleigh; vice-president, H. P. Grier, Statesville; secretary and treasurer, B. W. Levitt, Southern Pines. Executive committee: W. A. Wynne; J. B. Morris, Roxboro; H. P. Grier; H. P. Stephenson, Smithfield, and J. F. Hoyden, High Point.

Tube Lighting.

By D. McFarlan Moore.

THAT vacuum-tube lighting is advancing steadily is evidenced by the fact that the United States Government has again placed a large order with the Moore Electrical Company for additional apparatus. The order comprises 3,192 feet of one-and-three-quarter-inch lighting tube in twenty-eight sections. Each section of 114 feet will operate from its individual terminal box containing the transformer and regulating apparatus. It will be remembered that a perfect vacuum, if obtainable, would be the best insulator known, and therefore all so-called vacuum tubes must contain enough residual air or other gas to conduct the electricity, which produces the light, through them. About one ten-thousandths as much gas remains in a Moore tube as would be present if the vacuum pump had not been applied. Also, this one ten-thousandths must not vary either way more than one one-hundred-thousandths in order that the light in a vacuum tube remain at a constant intensity and also in order that the light may continue more than several minutes. In other words, to be practical the tube must be fed extremely minute particles of air or other gases at intervals of every few minutes. This is the function of the simple, though sensitive, automatic feed-valve within the terminal box.

FIG. 1.—MOORE TUBE WITH FRINK REFLECTOR IN REGISTRY DIVISION, NEW YORK CITY POST-OFFICE.

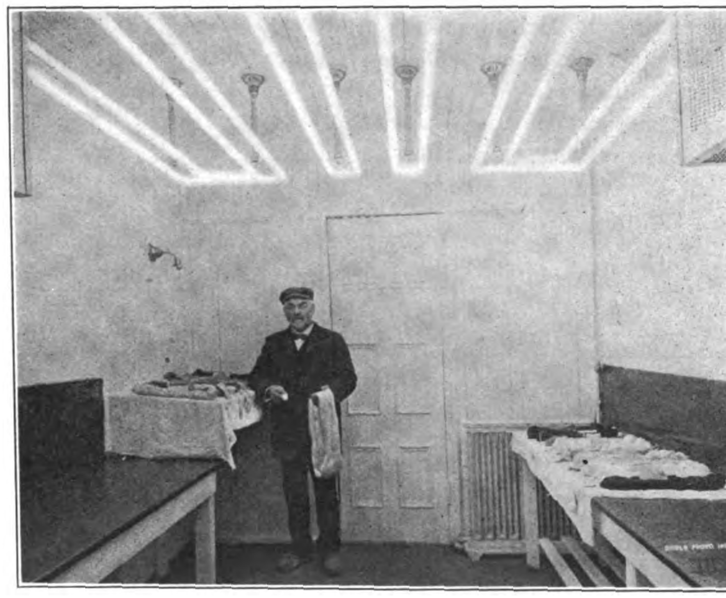

FIG. 3.—MOORE HAIRPIN UNITS IN THE COLOR-MATCHING DEPARTMENT OF THE WEIDMANN SILK MILLS.

When this valve is supplied with ordinary air a pink-colored light results, but if the oxygen of the air is automatically removed by simply causing the air intake to first pass through a bottle containing phosphorous, the gas which passes on to the feed-valve is practically pure nitrogen, which changes the color of the light to a golden yellow that resembles sunlight. It not only produces about thirty per cent more light, but has many other advantages over ordinary air and is, I believe, the most efficient form of light known for illuminating comparatively large areas. Some of the Moore tubes above referred to, which are about to be installed in the New York Post-Office, will be in the form of loops, that is, tubes, the ends of which return upon themselves and some in the form of perfectly straight single tubes, each one and three-quarter inches in diameter and 114 feet long.

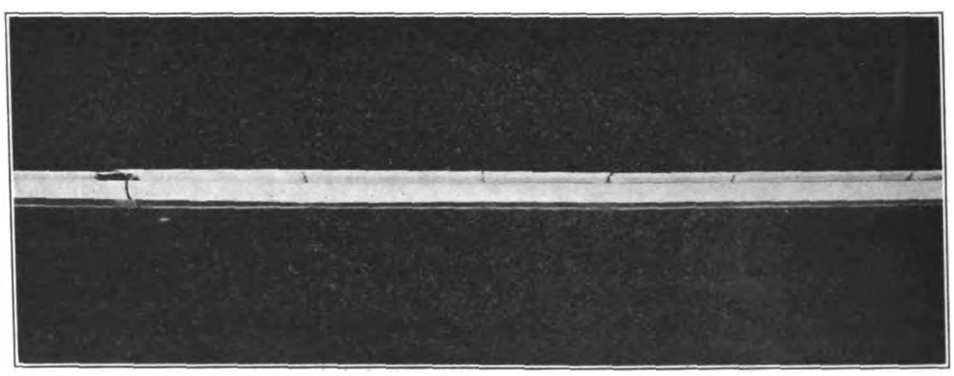

FIG. 2.—MOORE TUBE WITH FRINK REFLECTOR INSTALLED IN REGISTRY DIVISION, NEW YORK CITY POST-OFFICE.

Several months ago three new-style Moore tubes were installed in the New York Post-Office. Two of them are shown in Fig. 1. Heretofore Moore tubes have been installed in almost any length and shape, but it has been found very advantageous to decide on certain definite units. These three new tubes are in the forms of large hairpins—that is, the tubing extends fifty-seven feet from a terminal box and then returns upon itself, the two legs being only six inches apart. The total length of the entire light-giving tube is therefore 114 feet. It will be noticed that these units are held within a few inches of the ceiling by simple cast-iron fixtures placed every eight feet, and that they also support mirrored glass reflectors directly over the two legs of these tubes.

Fig. 2 shows the first Moore tube equipped with a corrugated mirrored-glass Frink reflector. Altogether such a combination makes a lighting device that lends itself with great facility to the solution of all illumination problems involving comparatively large areas. These new standard units are designed to operate on 220 volts, sixty cycles. They consume 2,400 watts and produce a distributed illumination of about 1,300 Hefners that is almost ideal. The ceiling is thirteen feet seven inches high, but with the two hairpin units in operation over the area shown there results an intensity of about nine Hefner feet on the tables used for sorting and distributing the mail. Due to the great responsibility involved in handling registered mail, it is important that a system of lighting be used that will permit all employés to be easily and clearly distinguished over long distances.

During the past few months the various claims for the Moore light have been amply corroborated by numerous investigations, tests and reports by thoroughly disinterested parties. As time passes the fact is emphasized that the fundamental principles of vacuum-tube lighting are correct and are in direct line with the tendency of the development in all classes of illuminating devices.

As regards maintenance charges, with its extremely long life, the vacuum tube will produce an illumination that is so well diffused that its illuminating efficiency is really better than is represented by five candle-power-hours for one cent, or about 0.25 watt per square foot of floor area for each foot-candle.

The determining of the best kind of gaseous conductors for vacuum tubes represents almost a virgin field of large dimensions, the discoveries in which will soon be of vital importance to the whole lighting industry. For example, helium gas offers large possibilities, but so far as color values are concerned it is very doubtful whether any form of gas will ever be obtained which will more closely imitate average natural diffused daylight than does carbon-dioxide in an automatically fed vacuum tube. It should be, and I firmly believe will be, adopted as the standard of light both as regards intensity and color. In fact, at the present time all other forms of light, so far as their color values are concerned, should be expressed in terms of the carbon-dioxide vacuum tube.

Fig. 3 shows one of the largest silk dyers in the world, Jacob Weidmann, in the color matching room of his large works at Paterson, N. J. It is well known that hardly any business requires more accurate color determinations than that of dyeing silk, yet it has been found by over a year's severe tests that in one respect matching colors under the Moore tubes is preferable even to diffused daylight, because the light of the tubes is always the same, while natural light varies widely under different atmospheric conditions and at different hours of the day, different months of the year, etc. The remarkable color values of the carbon-dioxide tube have proven valuable also in photography, where skylights have been equipped on their under sides with the tubes in a somewhat similar manner, so that, so far as the photographer's business is concerned, practically no difference exists between daytime and night-time.

The Moore vacuum tubes are aiding all the new forms of efficient lights in proving to central stations and other interested parties the at first seeming paradox that the cheaper the operating expense as regards current the greater their business will finally be due to the resulting increase in the quantity of light used.

Some Recent Developments in Arc-Lamp Construction.

By Dwight D. Miller.

PROFESSOR ANDREWS has said in his admirable paper on long flame arc lamps that "it is interesting to note that all the marked improvements made in arc lighting within recent years have been effected by using arcs of from ten to fifteen millimetres in length, and investigation shows that the great improvement in efficiency is directly or indirectly due to this increased length."

These new lamps can be arranged in two distinct classes: (1) Those arranged with inclined carbon rods and (2) those arranged with vertical or coaxial carbon rods as in the ordinary enclosed arc lamps. To the first class belong the "Polar" flaming arc lamp and the "Carbone" lamp, while the "Radiante" and "Radiante Economy" lamps belong to the second class.

As stated above, the "Polar" flaming arc lamp is arranged with inclined carbon rods which are secured in metal holders and slide down substantial guide rods converging at a point immediately below the economizer within the globe. Only one globe is used. The whole appearance of the lamp is very pleasing and attractive. The case is sheet steel and ordinarily furnished in black finish. The carbon holders are of ample strength and size to prevent heating. The lamp works on the differential principle—that is, the feeding mechanism is actuated by the resultant pull of a series and shunt magnet working at right angles to each other. This principle of operation insures a sensitive, nice and accurate feed of the carbons, resulting in a reliable and steady-burning arc. This feeding mechanism is absolutely shut off from the main body of the lamp; contained in a separate weather and dustproof case, provided with a rubber gasket and sealed before sending out. The guide rods, carbon holders and rods are below the feeding mechanism in the main body of the lamp, and are readily accessible for trimming by simply lowering the case by means of thumb hooks provided therefor.

The arc itself burns in the economizer, which takes the place of the inner globe in an ordinary enclosed arc lamp. This economizer is composed of highly refractory material, cup-shaped and deeply recessed. The effect of this economizer is (1) a concentration of the heat of the arc, producing thereby a greater intensity of light; (2) prevention of an excess of oxygen reaching the arc, which means longer life to the carbons; (3) as the carbons burn, a pure white metallic oxide is deposited in the inside of the economizer which is an excellent reflector, increasing the diffusion of light, and (4) protection of the arc from drafts. This protection is further supplemented by furnishing glass wind shields which project below the economizer and increase the burning hours ten per cent.

This type of lamp requires but forty-two volts at the arc with a current consumption of ten amperes—producing upwards of 3,000 candle-power. They burn most economically two in series on 110-volt and four in series on 220-volt circuits, with a consumption of 550 line watts per lamp.

Carbons cored with different metal salts are used, giving either a rich golden or brilliant white light as desired.

Too much stress can not be laid upon the substantial construction and reliable operation of these lamps. They burn steadily and uninterruptedly during the entire length of life of the carbons, and automatically cut themselves out when the carbons have burned their full time. Many thousands are in daily use and have been for several years past. In fact, ninety-five per cent of the exterior lighting in Berlin, Germany, is by means of the long-flame arc lamp.

The "Polar" flaming arc lamp is handled in this country in two sizes. One, known as the short type, two feet eight inches long over all, takes a carbon 400 millimetres in length, burns twelve hours

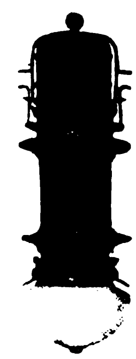
"POLAR" FLAMING ARC LAMP.

on one trim and weighs twenty-six and one-half pounds, while the long-type lamp is three feet six inches over all, taking a carbon 650 millimetres long, burns twenty hours on one trim and weighs thirty-three pounds. The lamp burns equally well when connected in multiple and on any circuit.

It is interesting to note that a very successful test of this lamp has been completed at one of the largest power-houses in New York city, burning three in series on a 200-volt, twenty-five-cycle alternating-current circuit. The test lasted through a period of three weeks, during which time the lamp demonstrated beyond the question of a doubt its stability on such a circuit.

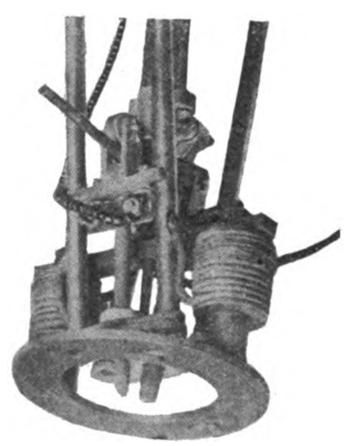
We come now to the second lamp in Class 1, namely, the "Carbone" lamp. Here again we have a lamp working on the differential principle with inclined carbons converging at a point within the economizer in the globe. In outward appearance the "Carbone" lamp is very similar to that of the "Polar" flaming arc lamp, the standard finish of case and the special shaped "Pilz" globe, a patented article, being the same in both cases.

By the use of pure carbon rods all fumes and gases are avoided and we obtain what is the most striking feature of this lamp, namely, its light, which is pure white, of great brilliancy and purity, and absolutely steady.



"CARBONE" LAMP WITH MUSHROOM GLOBE.

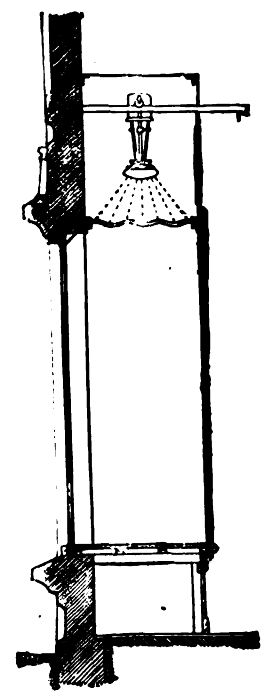
The "Carbone" lamp works on a high arc voltage—eighty-five volts for the direct-current and seventy volts for the alternating-current lamp—so that it burns in multiple on 110 to 120-volt and two in



MAGNETIC-RING CONTROL OF THE "CARBONE" LAMP.

series on 220 to 240-volt circuits. The effect of this high voltage is that the crater of the arc forms on the very end of the carbon tips and is held fixed there by a very ingenious device, patented by Mr. Carbone, known as magnetic-ring control. This consists of a closed metallic circuit in the form of a ring, concentric with and placed just above the economizer of the lamp. On this ring are mounted two solenoids with a soft iron bar connected across the tops, and the position of the arc is rigidly controlled by the magnetic leakage from this closed circuit. Naturally, the leakage is greatest where the solenoid cores enter the ring, and this is further increased by boring holes in the ring itself in such a manner that the field produced by this leakage holds the arc in the desired position, spreading it out in a semicircular, shadowless and steady flame.

The efficiency of this lamp is very high, taking but 0.6 of a watt per candle-power, and producing 1,350 candle-power of pure white light with a consumption



CROSS-SECTION OF SHOW-WINDOW, SHOWING METHOD OF CONCEALING LIGHT.

of only eight amperes. It is handled in two sizes of approximately the same dimensions and weight, as in the case of the "Polar" flaming arc lamp, the short type burning eleven hours and the long type sixteen hours. This lamp also burns on twenty-five to 150 cycles, alternating current.

The science of illumination requires that not only shall there be the proper quantity and quality of light, but also, what is more essential, that this light shall be correctly diffused. By means of various types of shades, globes and reflectors, direct, semi-direct or indirect illumination can be produced, according to the specific requirements of the particular problem under consideration. By using the special-shaped "Pilz" globe the distribution of light becomes exceedingly uniform. Again, by using special shapes and shades of glass and opaque reflectors the light is thrown in various directions and reflected back to the eye much softened and properly diffused. All shadows are also eliminated.

We now come to the second class of lamps, with coaxial carbon rods. This construction is found in the "Radiante" and "Radiante Economy" lamps. These lamps are a direct outgrowth of the "Carbone" lamp, and put upon the market to meet the demand for a longer-life lamp. Thus they combine the pure white, steady, daylight effect of the "Carbone" lamp with long life and efficiency.

Here again pure carbon rods are used with soft cored centres. The rods are arranged vertically one over the other as in the well-known enclosed-arc construction but provision is made for lengthening the arc, thus eliminating all shadows from the lower carbon. The lower carbon is stationary and the upper feeds down as it burns away. The proper trimming height of the lower carbon is marked by a notch in the lower carbon holder which is centered accurately with the upper holder ensuring perfect alignment of carbon rods and an even, steady and economical burning of the carbons. The feeding mechanism is of simple construction, consisting of a magnet working against gravity. This control is positive in its action, accurate and nice in its adjustment, which results in a steady arc. The arc is only partially enclosed, the object being to obtain long life of carbons and yet avoid the disadvantages of the completely enclosed arcs, such as bluish color and unsteadiness of flame. The lamps are very attractive and pleasing in appearance, the same material and standard finish of case and "Pilz" globe being used as in the case of the "Polar" flaming arc and "Carbone" lamps.

The efficiency is again very high as the lamp takes but 0.5 of a watt per candle-power.

These lamps also burn with a high-voltage arc, requiring eighty volts, and at present are designed to burn on direct-current circuits only, in multiple on 110 to 120 volts, and two in series on 220 to 240 volts; but an alternating-current lamp of this type is promised by the manufacturers in a short time. They are made in two sizes: The "Radiante," two feet seven and one-half inches long over all, takes a carbon 400 millimetres in length, burns fifty hours on one trim, and weighs eighteen pounds, and the smaller type, known as the "Radiante Economy" lamp is twenty-one inches over all, takes a carbon 300 millimetres in length, burns thirty-two hours on one trim, and weighs nine pounds.

The "Radiante," with a consumption of eight amperes, gives a light of 1,200 candle-power, and the "Radiante Economy," with four amperes, gives 600 candle-power of pure white, steady light.

As in the case of the "Carbone" lamp different degrees and types of illumination can be obtained to meet specific requirements, by using the same kind of shades, globes and reflectors. In the case of the "Radiante Economy" lamp a milk glass reflector is provided in addition. The field of these lamps is almost unlimited, but they are especially recommended for lighting interiors where the highest grade of lighting is essential and desired, and true color reproduction necessary.

No hard and fast rules can be laid down as to which type of illumination should be used, and each case should and must necessarily be considered according to its specific requirements and the effect it is desired to obtain, but it is obvious that where the ceilings are high or strong light necessary, as for instance, where black threads and material are treated, direct illumination is the logical choice. While, on the other hand, in rooms with low ceilings or where no shadows are desired, semi-direct or indirect lighting would give the better effect.

A very novel, as well as effective and economical, method of lighting show windows, known as "Standard Show Window Illumination," in connection with the "Carbone," "Radiante" and "Radiante Economy" lamps, has just been introduced in this country. It seems that the majority of merchants have been and are laboring under the fallacy that the more and stronger light they have the better the customers can see the goods displayed, overlooking entirely that very vital point of diffusion. This fallacy becomes at once apparent if, on a perfectly clear summer day, one goes out at noontime, when the sun is directly overhead and its light least diffused by atmospheric conditions, and tries to look directly at it. The effect is blinding. Yet here is the strongest and best type of light known, but the difficulty is there is no diffusion. The object of show-window illumination is to attract passersby and cause them to look at the goods therein displayed. This is done most effectively when the source of light is entirely concealed, because then the whole attention can be concentrated on the contents of the window and the eye left entirely free from any glare. The illustration herewith gives a cross section of a show window showing this method of concealing the light and how the desired effect is obtained. The lamps are arranged high up in the window and entirely shut off from the gaze of the onlooker by heavy fluted glass, while the light itself is diffused and the window illuminated with a pure white light, bringing out the color values of the goods accurately.

These lamps are the product of the Carbone Light Gesellschaft, of Berlin, Germany, and are handled exclusively in the United States and Canada by the electrical department of Fox Brothers & Company, 126-130 Lafayette street, New York city.

THE KUZEL LAMP.

BY PAUL M'JUNKIN.

The Kuzel lamp continues to make substantial progress, and although it is not yet manufactured in this country, negotiations are progressing toward that end. In the meantime increasing quantities are being imported, as the European manufacturers are able to spare lamps for this market.

This lamp has been the standard in Europe for some months, and burns in any position. The standard candle-power is twenty American candles, twenty-five watts, for the 110-volt lamp. This type of lamp is made almost to the entire exclusion of the higher candle-powers.

The lamp is rugged physically, which is due partly to the ingenious anchoring employed, but principally to the superior quality of the filament itself. The colloidal process employed by Dr. Kuzel produces a filament of perfect homogeneity and great elasticity, as well as purity.

The lamps at present are made in bulbs of practically equivalent sizes to those used for carbon lamps of corresponding candle-powers, and are fitted with the same style of base as is used on all low-candle-power carbon-filament lamps.

The Kuzel lamps are now manufactured in Austria, Germany, Sweden and Great Britain, and the solidarity of the business is typified by the new factory which has been erected in Vienna. This factory, which is being operated by Kremenezky, has a present capacity of 25,000 lamps per day. Every precaution has been made to increase the plant and equipment to 60,000 lamps per day as rapidly as it may be necessary. Kremenezky has been recognized for years as the leader in high-class carbon-lamp manufacture in Europe, and he has naturally devoted his best energies to the equipping of the new tungsten-lamp factory with the most perfect machinery that has been developed for tungsten-lamp manufacture up to the present time.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

TWIN CITY RAPID TRANSIT COMPANY.

The report of the Twin City Rapid Transit Company, Minneapolis, Minn., for the month of July and seven months ended July 31, shows July gross of $606,373; expenses, $278,138; July net, $328,235; charges, taxes and preferred dividend, $128,361; July surplus, $199,874. Seven months' gross, $3,589,222; expenses, $1,813,728; seven months' net, $1,775,494; charges, taxes and preferred dividends, $877,788; seven months' surplus, $897,706.

UNITED STATES TELEPHONE COMPANY.

The annual report of the United States Telephone Company, of Cleveland, Ohio, for the year ended December 31, 1907, shows gross of $435,013; expenses and taxes, $184,135; net, $250,878; other income, $34,965; total income, $285,843; charges, $116,877; balance, $168,966; preferred dividends, $51,150; balance, $117,816; common dividends, $69,750; surplus, $48,066.

UNITED RAILWAYS COMPANY.

The report of the United Railways Company, of St. Louis, Mo., for the month of July and seven months ended July 31, shows July gross of $898,210; expenses, $578,528; July net, $319,682; charges, $232,852; July surplus, $86,830. Seven months' gross, $6,061,765; expenses, $3,946,037; seven months' net, $2,115,728; charges, $1,618,399; seven months' surplus, $497,329.

NEW ORLEANS RAILWAY AND LIGHT.

The report of the New Orleans (La.) Railway and Light Company and controlled companies for the six months ended June 30 shows gross of $3,054,535; expenses, $1,714,429; net, $1,340,106; charges, $991,521; surplus, $348,585; other deductions, $27,144; balance, $321,441. Of the balance there is to be reserved $23,338 for rehabilitation of tracks and cars and other equipment.

CUYAHOGA TELEPHONE COMPANY.

The annual report of the Cuyahoga Telephone Company, of Cleveland, Ohio, for the year ended December 31, 1907, shows gross of $781,586; expenses and taxes, $346,913; net, $434,673; charges, $207,458; surplus, $227,215; dividends, $131,222; net surplus, $95,993.

CUMBERLAND TELEPHONE AND TELEGRAPH COMPANY.

The report of the Cumberland Telephone and Telegraph Company for the month of July and seven months ended July 31 shows July gross of $500,094; expenses, $283,473; July net, $216,621; charges and taxes, $37,347; July surplus, $179,274. Seven months' gross, $3,557,072; expenses, $2,065,681; seven months' net; $1,491,391; charges and taxes, $260,357; seven months' surplus, $1,231,034.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY.

The report of the American Telephone and Telegraph Company for the first seven months of 1908 shows gross earnings of $15,097,966; expenses, $1,223,807; net earnings, $13,874,161; interest, $4,026,937; balance, $9,847,223; dividends, April and July, $5,262,056; surplus, $4,585,168.

WESTCHESTER ELECTRIC RAILROAD COMPANY.

The report of the Westchester (N. Y.) Electric Railroad Company for the quarter ended June 30 shows gross of $97,747; expenses, $104,102; deficit, $6,355; other income, $137; deficit, $6,218; charges, $3,819; total deficit, $10,037.

MONTREAL STREET RAILWAY COMPANY.

The report of the Montreal Street Railway Company for the month of July and ten months ended July 31 shows July gross of $326,524; expenses, $162,413; July net, $164,111; charges, $65,012; July surplus, $99,098. Ten months' gross, $2,999,187; expenses, $1,814,428; ten months' net, $1,184,159; charges, $515,888; ten months' surplus, $668,971.

SEATTLE ELECTRIC COMPANY.

The report of the Seattle Electric Company, Seattle, Wash., for the month of June and twelve months ended June 30 shows June gross of $358,207; expenses, $202,875; June net, $155,332; charges, taxes and sinking fund, $93,695; June surplus, $61,637. Twelve months' gross, $4,384,438; expenses, $2,594,122; twelve months' net, $1,790,316; charges, taxes and sinking fund, $1,017,674; twelve months' surplus, $772,642.

GALVESTON-HOUSTON ELECTRIC COMPANY.

The report of the Galveston-Houston (Tex.) Electric Company for the month of June and twelve months ended June 30 shows June gross of $92,442; expenses, $53,235; June net, $39,207; charges, taxes and sinking fund, $21,009; June surplus, $18,198. Twelve months' gross, $1,069,016; expenses, $625,598; twelve months' net, $443,418; charges, $237,977; twelve months' surplus, $205,441.

MINNEAPOLIS GENERAL ELECTRIC COMPANY.

The report of the Minneapolis (Minn.) General Electric Company for the month of June and twelve months ended June 30 shows June gross of $70,766; expenses, $31,838; June net, $38,928; charges, taxes, $31,507; June surplus, $7,421. Twelve months' gross, $955,510; expenses, $434,040; twelve months' net, $520,670; charges, $348,021; twelve months' surplus, $172,649.

BUFFALO & LAKE ERIE TRACTION COMPANY.

The report of the Buffalo & Lake Erie Traction Company for the quarter ended June 30 shows gross of $134,656; expenses, $91,937; net, $42,719; other income, $5; total income, $42,724; charges, $95,640; deficit, $52,916.

INTERBOROUGH RAPID TRANSIT COMPANY.

The report of the Interborough Rapid Transit Company, New York city, for the quarter and twelve months ended June 30 shows gross earnings for the quarter of $6,248,224; operating expenses, $2,796,102; net earnings, $3,452,142; other income, $305,307; total income, $3,757,449; interest and taxes, $847,622; rentals, $2,025,485; total charges, $2,873,107; surplus, $884,342. For the fiscal year the gross earnings were $24,059,290; operating expenses, $10,722,695; net earnings, $13,336,604; other income, $1,220,170; total income, $14,556,074; charges, $10,856,116; surplus, $3,700,658.

NORTHERN OHIO TRACTION AND LIGHT COMPANY.

The report of the Northern Ohio Traction and Light Company for July and seven months shows July gross of $200,392; expenses, $105,377; July net, $95,015; charges, $44,052; July surplus, $50,963. Seven months' gross, $1,039,134; expenses, $624,037; seven months' net, $415,097; charges, $305,212; seven months' surplus, $109,885.

SCHENECTADY RAILWAY COMPANY.

The report of the Schenectady (N. Y.) Railway Company for the quarter ended June 30 shows gross of $220,110; expenses, $158,559; net, $61,551; other income, $916; total income, $62,467; charges, $30,883; surplus, $31,584.

BIRMINGHAM RAILWAY, LIGHT AND POWER COMPANY.

The report of the Birmingham (Ala.) Railway, Light and Power Company for the month of July and seven months ended July 31 shows July gross of $170,-

777; expenses and taxes, $113,425; July net, $57,352; charges and sinking fund, $44,075; July surplus, $13,277. Seven months' gross, $1,235,602; expenses and taxes, $796,202; seven months' net, $439,400; charges and sinking fund, $307,370; seven months' surplus, $132,-030.

MEMPHIS STREET RAILWAY COMPANY.

The report of the Memphis (Tenn.) Street Railway Company for the month of July and seven months ended July 31 shows July gross of $140,461; expenses and taxes, $89,017; July net, $51,444; charges, $35,465; balance, $15,979; reserve funds, $2,500; July balance, $13,-479. Seven months' gross, $915,529; expenses and taxes, $583,418; seven months' net, $332,111; charges, $243,905; balance, $88,206; reserve funds, $17,500; seven months' surplus, $70,706.

DETROIT UNITED RAILWAY COMPANY.

The report of the Detroit (Mich.) United Railway Company for July and the seven months ended July 31 shows July gross of $679,447; expenses and taxes, $417,869; July net, $261,577; other income, $6,462; total income, $268,-039; charges, $135,978; July surplus, $132,061. Seven months' gross, $3,964,-875; expenses and taxes, $2,528,176; seven months' net, $1,436,698; other income, $35,072; total income, $1,471,770; charges, $948,952; seven months' surplus, $522,818.

TOLEDO RAILWAYS AND LIGHT COMPANY.

The report of the Toledo (Ohio) Railways and Light Company for July and seven months shows July gross of $199,-237; expenses, $111,665; July net, $87,-572; other income, $91; total income, $87,663; charges and taxes, $71,751; July surplus, $15,912. Seven months' gross, $1,429,612; expenses, $794,054; seven months' net, $635,558; other income, $2,874; total income, $638,432; charges and taxes, $491,887; seven months' surplus, $146,545.

KNOXVILLE RAILWAY AND LIGHT COMPANY.

The report of the Knoxville (Tenn.) Railway and Light Company for July and seven months ended July 31 shows July gross of $51,720; expenses and taxes, $26,330; July net, $25,390; charges, $11,483; balance, $13,907. Seven months' gross, $323,820; expenses and taxes, $171,027; seven months' net, $152,-792; charges, $80,160; seven months' surplus, $72,632.

NASHVILLE RAILWAY AND LIGHT COMPANY.

The report of the Nashville Railway and Light Company, Nashville, Tenn., for the month of July and seven months ended July 31, shows July gross of $127,-936; expenses and taxes, $78,215; July net, $49,721; charges, $33,101; balance, $16,620; reserve funds, $3,858; July surplus, $12,762. Seven months' gross, $887,986; expenses and taxes, $542,399; seven months' net, $345,587; charges, $221,162; balance, $124,425; reserve funds, $26,528; seven months' surplus, $97,897.

LITTLE ROCK RAILWAY AND ELECTRIC COMPANY.

The report of the Little Rock (Ark.) Railway and Electric Company for July and seven months ended July 31 shows July gross of $53,560; expenses and taxes, $30,095; July net, $23,465; charges and sinking fund, $10,874; surplus, $12,-591; reserve funds, $3,000. Seven months' gross, $364,293; expenses and taxes, $198,717; charges and sinking fund, $68,875; reserve funds, $21,000; seven months' surplus, $95,701.

BOSTON ELEVATED RAILWAY COMPANY.

The report of the Boston Elevated Railway Company for August shows an improvement over the results for July. Figures for the last four months compare as follows: May, $1,214,000; June, $1,224,000; July, $1,158,000; August, $1,133,000. While the receipts show a comparative decline in gross for two successive months, the actual decrease in gross receipts for August was $37,000, a loss of 3.1 per cent, which compares with a July decline of $76,000, or 6.1 per cent.

Canadian Independent Telephone Association.

The third annual convention of the Canadian Independent Telephone Association was held in Toronto, Ontario, on September 9. The following papers were presented at the meeting: "Bell Connections," Dr. W. Doan; "Independent Telephones at Railway Stations," C. Skinner; "Mutual *versus* Joint Stock Companies," A. R. Walsh; "Rural Line Equipment and the Best Way to Serve the Farmers," F. A. Dales; "Rates to Be Charged and the Best Form of Collecting," A. Hoover; "To What Extent Should Free Service Be Given?" A. D. Bruce; "Division of Territory Between Telephone Companies," Levi Moyer; "Toll Line Connections: How Best Effected," Alex Neilson and Henry Sneath; "Western Situation and Its Future," F. Dagger; "Our Interests in Towns and Cities," M. Gee; "The Independent Movement in Towns and Rural Communities," T. R. Mayberry, M.L.A.; "Exclusive Franchises and Government Regulation," Dr. A. Ochs.

BOOK REVIEW.

"Wissen and Können." Dr. Richard Henning. Johann Ambrosius Barth, Leipzig, Germany. Boards. 199 pages. 6x9 inches. 61 illustrations. Price 4 marks ($1.25).

This is the eighth volume of a series of books ("Knowledge and Ability") published at regular intervals, by different authorities, on pure and applied science, and gives the history and development of telegraphy and telephony. The author goes back to ancient times and shows how the old Greeks were eager to develop means for a speedy transmission of intelligence to which the term telegraph fitly applied; starting with a wigwagging of hands and flags and the building of bonfires. A further development was the erection of signal towers of the most primitive type. With the advent and development of electricity came vast possibilities. The various types of magneto-electric and chemical-electrical telegraphs are described, up to and including the Morse telegraph and cipher code. The modern telephone and cable telegraph are described and illustrated, wireless telegraphy, however, not being mentioned.

Probably the most interesting feature of the work is the statement of the opinions of the inventors of the various instruments and devices at the time of their invention.

The volume is written in a clear and forcible manner and should appeal not only to the engineer but to the every-day reader.

The Buckeye Electric Company Conference.

The Buckeye Electric Company, Cleveland, Ohio, during the week of August 29 held its most successful annual conference. During the week there were in attendance fifteen direct branch managers and salesmen of the company, as well as about ten guests. Everything in connection with the incandescent-lamp business was discussed very thoroughly, especial attention being devoted to the discussion of the newer types of lamps. The company is confident that this meeting will bring excellent results, both to itself and its customers.

The company is starting the season in better shape this year than it ever did before, and in substantiation of this makes the statement that its business for August, 1908, is at least twenty per cent greater than it was for August, 1907.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Just-Wolfram Lamps for 220 Volts.

To overcome the difficulties which have appeared in the manufacture of long metal filaments of small cross-section, and to turn out serviceable metal filaments for forty watts at 220 volts, for commercial purposes, the Physikalisch Technische Reichsanstalt, at the request of the Wolfram Company, made extensive tests with fifty-watt lamps operating at 220 volts. The tests proved that the intensity of light between the high and low-voltage lamps varied but little, and the durability and life of the lamps were the same. The test of the Reichsanstalt consisted of burning twelve lamps for 1,600 hours each on direct current. The results showed that the average life of the lamps was 1,141 hours. Up to 1,400 hours the average intensity of the light remained the same and the specific current consumption increased 1.5 per cent, being 1.23 watts per candle (Hefner). A test at the factory on alternating current gave, after 1,000 hours, 1.25 watts per candle (Hefner), with an average life of 1,224 hours.—*Translated and abstracted from the Journal für Gasbeleuchtung und Wasserversorgung (Munich), August* 8.

The Transmutation of Copper.

Sir William Ramsay and A. T. Cameron announced, about a year ago, that they had observed the production of the alkaline metals and lithium in solutions of copper salts submitted to the action of radium emanation. It was concluded that in the presence of the emanation, copper underwent a degradation into the elements, potassium, sodium and lithium. A recent issue of *Comptes Rendus* of the Paris Academy of Sciences contains an article by Mme. Curie and Mlle. Gleditsch, giving an account of the attempts that they have made to repeat this experiment. The extreme difficulty of obtaining chemical products free from lithium is pointed out. This metal was found in distilled water and in nearly all the reagents. If a reagent free from lithium is allowed to stand in a glass vessel, traces of this metal are found after some time. Both opaque and transparent quartz were found to contain notable amounts, the latter furnishing the larger proportion. The experiments were carried out in such a manner that the solutions came in contact with platinum only. The water and acids necessary for the experiment were redistilled from platinum and preserved in platinum bottles. After this treatment no lithium could be detected in the residue from twenty-five cubic centimetres of nitric acid, twenty-five cubic centimetres of hydrofluoric acid, and 250 cubic centimetres of water. About the same quantities of copper and radium emanation as those used in the original experiment were employed. Spectroscopic examination of the salt residue obtained showed it to consist of salts of sodium with a little potassium. The presence of lithium could not be proved. The authors conclude that they have been unable to confirm the experiments of Messrs. Ramsay and Cameron.—*Abstracted from Nature (London), August* 20.

The Lucerne-Engelberg Hydroelectric Transmission System, Switzerland.

For supplying current to the city of Lucerne and vicinity, the water of a natural collecting basin, of 2,471,000 cubic feet capacity, fed by streams and glaciers of the Engelberg, is utilized at a power plant at Obermatt, about seventeen miles from Lucerne. Current is transmitted at 27,000 volts. The turbines, of which four are at present installed, are of the impulse type, operating under a head of 1,023 feet. They are connected to 2,000-horse-power, fifty-cycle, 6,000-volt generators, making 300 revolutions per minute. These generators have a capacity of 1,850 kilovolt-amperes, three-phase, or 1,380 kilovolt-amperes, single-phase. This plant also contains one reserve unit for the Stansstad-Engelberg railway system. This is an impulse turbine coupled to a 540-kilovolt-ampere, 780-volt, 32.5-cycle, three-phase generator, which has a bus-bar system of its own. The current from the main generator is stepped up by 700-kilovolt-ampere single-phase transformers to 27,000 volts. On each side of the transformers are two separate ring bus-bar systems, one for single-phase (light), and the other for three-phase (power). All the transformers are single-phase. There are three transformers for single-phase light supply and two groups of three single-phase transformers, connected in delta, for power service. Between the power transformer groups is one single-phase transformer which serves as a reserve unit for both groups. The transformers are of the oil, water-cooled type. If the water supply falls below the normal an automatic electric signal system gives notice of this condition. The aerial conductors are carried on lattice-steel towers. A feature of the construction is the cantilever arrangement of supporting them above the shores of Vierwaldstaetter Lake. There are several transformer stations along the line which step the line voltage down to 5,000 and 350 volts for local distribution. The whole system is well protected by lightning arresters among which is the combination of the horn lightning arrester and water-flow grounder, a system much favored in Continental practice.—*Translated and abstracted from the Elektrotechnische Zeitschrift (Berlin), August* 6.

The Use and Conservation of Water-Power Resources.

H. von Schon, the author of the present article, holds that water power is the expression of the dynamic energy of falling water, eighty per cent of which may be realized as mechanical energy, and seventy per cent as electrical energy. Theoretically, all the fall and flow of a river is available for power development, but the practical limit is a question of economics. Successive dams may be placed so that the lower pool of one becomes the upper of the next, but this may prove, in cases, wasteful in cost, as economic dam sites are not always arranged by nature with such regularity. The volume of available flow is as important a factor as the fall, as the product of fall and weight of volume represents the source of water-power energy. Without the consideration of flood-flow storage the determination of available flow basis should be developed from a consideration of the market demand, and the value of the output, in order to decide how large an investment in auxiliary power plant or electric storage equipment the enterprise will stand; and the capacity of this, added to the low-flow output, will point to the volume which may be accepted as the available flow. As far as accurate data are concerned, we find ourselves in the position of the man who has done business without keeping books. For some time to come we can not take an inventory of our water-power asset. It appears that from data collected by the author, the undeveloped water power of New England, New York, Pennsylvania, the middle and southern states, and the Pacific coast watershed, sums up to a grand total of 10,000,000 horse-power, based on the unconserved flow. A reasonable estimate of our available water-power assets appears to be about 20,000,000 horse-power, representing the annual equivalent in steam fuel of about 300,000,000 tons. At $100 per horse-power this would require an investment in water-power works of approximately $2,000,000,000, and a further investment in hydraulic and power-generating equipment, at $50 per horse-power, of $1,000,000,000. At a valuation of $35 per horse-power per annum—about 0.75 cent per kilowatt-hour—for continuous service, the income at three per cent represents a total earning on about $20,000,000,000. Results which will conserve the entire benefits of the water-power resources, and render this conservation economical and profitable, can be realized only by the combined resources and powers of the whole people. The investigations of flood-storage opportunities should be carried on by the state. If storage of flood waters were determined to be feasible, a state commission should have authority to designate the reservoir sites as a state water and forest reserve, and acquire title by condemnation to sufficient land to control the reservoir feeders. They should then lease the same to the lowest bidder for the construction of the necessary storage works and their maintenance and operation, fixing the amount of tolls at a certain per cent on the investment for land and works, which should be covered by a state bond issue. The power development works should be exempt from taxation for a period of years, during which the principal of the capital investment remains a charge against them, conditioned upon a specified programme of serial retirement of the securities and of their total redemption. The water-power company should be chartered by the state, the latter reserving the right to periodical inspection of its works and of regulation of the rates charged for the product. Finally, the Federal Government, upon the request of the state, should examine the feasibility of creating navigation on the stream, its extent and cost; and if the findings are satisfactory, a proper navigation lock should be constructed with each power development dam, under the supervision of the government, and the cost thereof and of buildings and appurtenant navigation locks should be defrayed by the United States Treasury, as well as the expense of any canalization or deepening of channels between such power sites. This would secure the co-operation of individual enterprise, and of the powers of the community, state and nation, toward the object of conserving the water and all its collateral assets, thereby placing within the reach of every community hydroelectric power products.—*Abstracted from the Engineering Magazine (New York), September.*

Illumination and Our Eyesight.

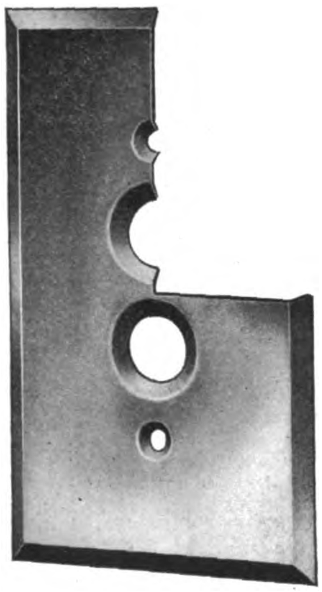
The introduction of powerful electric incandescent lamps fitted with metallic filaments has increased the complaints of the deleterious effect upon the eyesight of the high illumination which is being adopted in many places where artificial light is employed. Lamp manufacturers are anxious to meet the objections, and the question came up recently at the annual meeting of the German electrical engineers, the Verbund Deutscher Electrotechniker. In a paper by F. Schanz, M.D., and Dr. C. Stockhausen it is pointed out that the ultra-violet rays are a source of danger, and that with the improvement of our lamps we have been receiving more and more ultra-violet rays. The spectrum of the light of a paraffine or wax candle and of an ordinary rape-seed oil wick is hardly longer than that of the visible rays. When the combustion is rendered more energetic by the aid of a chimney, the ultra-violet rays increase. In the incandescent gas light, in the electric and Nernst lamps, and particularly in the mercury arc, ultra-violet rays abound. These conditions are masked to a certain extent when we surround the sources of light with glass shades, for the glass absorbs a good many rays; but ultra-violet rays find their way through ordinary glass. That ultra-violet rays, especially of very small wave-length, set up irritation of the skin, is sufficiently known from extended observation and special experiments. These rays cause injury and seem also to cure diseases under certain conditions. At any rate, they are active. Rays of greater wave-lengths are less directly injurious. Some physicians, like Dr. Schanz, ascribe to them the so-called opthalmia electrica, which resembles snow blindness. Both the crystal lens and the retina of the eye are said to be affected by ultra-violet rays. Dr. Voege, of the physical government laboratory of Hamburg, has recently described experiments which he undertook as a result of the paper before mentioned. His chief announcement is that sunlight is far richer in ultra-violet rays than most of our modern artificial lights, with a few exceptions. In his experiments Dr. Voege makes use of a kind of photometric arrangement. Two dim glass plates are so placed that they appear equally bright to the observer. The one plate is illuminated by the diffused light of the sky, the other by the lamp under test. When the photometric adjustment has been effected, photographs are taken, always under exactly similar conditions, with similarly emulsified plates. As the field consists of two halves, we should get two dark spots of unequal intensity if there is any difference in the proportion of actinic rays. The field is further subdivided by placing a screen of window glass over the upper half, and a screen of quartz glass over the other. Thus four sectors are obtained. Dr. Voege concludes that, provided we arrange our lamps in such a way that we do not directly see the glaring filament and the arc, the eye receives less ultra-violet light from the lamps than it receives with sunlight of equal intensity. The eye, however, does not resemble a sensitized plate, and we have to rely upon our own experience unless we are ready to submit ourselves to dangerous experiments, such as Dr. Burch and others have undertaken for the direct study of fatigue of the eye. Individuality, no doubt, plays an important part. As long as we do not understand the problem general care is most advisable. Too much light may be nearly, if not quite, as bad as too little.—*Abstracted from Engineering (London), August 21.*

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

The "H. & H." Struck-Up Plate.

The Hart & Hegeman Manufacturing Company, Hartford, Ct., has placed on the market a struck-up plate for push switches. An idea of the appearance of this plate can be gained from the accompanying illustration. This device is made in single plates only, and can be used with other makes of push switches



"H. & H." Struck-Up Plate.

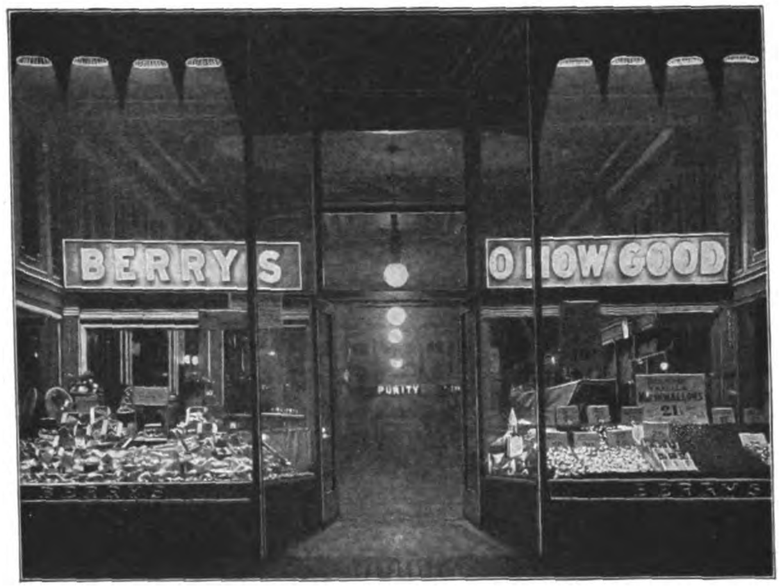
as well as the "H. & H." The plate is made of sheet brass 0.05 inch thick. It can be bought for quite a little less than a solid plate, and, the company states, looks just as well and will answer every purpose. The finishes are nickel, old brass, brush brass and oxidized copper.

Westinghouse Postponement.

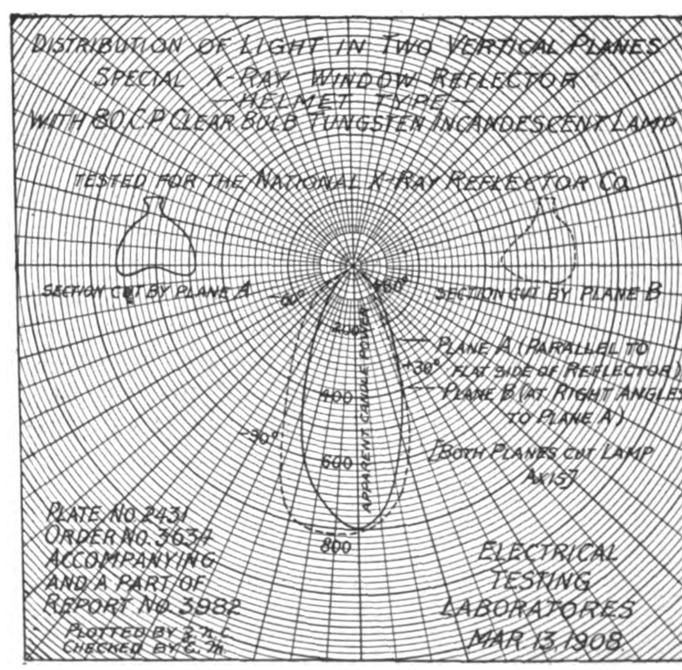
It has been announced that there will be no meeting of the readjustment committee of the Westinghouse Electric and Manufacturing Company to hear the report of the creditors' committee until September 21. September 1 was the last day for the acceptance of the proposed readjustment plan by the creditors and shareholders. The plan provides for the acceptance of new full-paid stock by the mercantile creditors in exchange for their claims; for a pro rata subscription by present shareholders to $6,000,000 new stock for working capital; and for the acceptance by banking creditors of fifty per cent in convertible five per cent bonds and of fifty per cent in fifteen-year five per cent notes.

The New Helmet-Tungsten System of Show-Window Lighting.

The accompanying illustration of Berry's candy-store windows, at 180 State street, Chicago, Ill., affords an interesting demonstration of up-to-date methods in illuminating show windows. The dimensions of the window are eight and one-half feet long, six feet deep and twelve feet high. The former lighting arrangement of the windows consisted of twenty-five feet of continuous trough reflector installed at the top of the window on all four sides, and operated with twenty-five sixteen-candle-power lamps giving approximately 1,250 downward candle-power, consuming 1,400 watts. The new installation consists of four Helmet reflectors, each reflector equipped with a



Show-Window Illumination with Special X-Ray Reflector of the "Helmet" Type.



Distribution of Light in Two Vertical Planes with Special Window Reflector of the "Helmet" Type, Equipped with Eighty-Candle-Power Clear-Bulb Tungsten Lamp.

100-watt tungsten lamp. This gives an illumination intensity of 3,200 candle-power in each window, with a consumption of 400 watts, effecting an actual saving of 1,000 watts per window, and giving an increased illumination of almost double the candle-power.

The Helmet reflector operates at its best efficiency in windows over ten feet high. This reflector was primarily designed on scientific lines for window lighting in connection with sixty or 100-watt tungsten lamps. The photometric curves shown herewith give an intensity of illumination of 800 downward candle-power.

The company states that with the original installation the total maintenance cost per year was $280, as against a cost for similar maintenance of $88 with the new installation.

The Displaying of Lighting Fixtures.

The proper displaying of lighting fixtures in the showrooms of the various dealers throughout the country has long been an unsolved problem, and until recently few attempts have been made to so arrange and display fixtures that both the artistic and lighting effects of different units could be effectively demonstrated.

In many instances it has seemed that the chief object of a display room has been to collect and assemble in as small a space as possible, a large and varied assortment of metal structures, and place them regardless of style or size. Consequently the prospective buyer is led into a maze of metal and frequently emerges from the display room with rather a hazy idea of just what has been seen or purchased.

Recognizing that this method of displaying fixtures is not conducive to good selection by the customer or satisfactory sales, the Central Electric Company, Chicago, has completely equipped a series of artistic display rooms, one room of which is shown in the accompanying illustration. The other rooms are all conveniently connected and fully equipped with appropriate furnishings.

Each fixture is so located and connected that the lighting effects as compared with another style of fixture, can readily be shown. Crowding of fixtures has been avoided by using large rooms, the furnishings of which are selected with good judgment and taste.

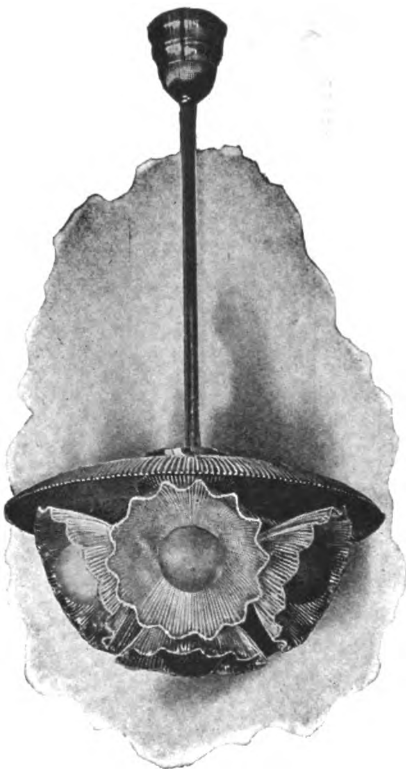
Illuminating and consulting engineers, architects and contractors find the conveniences offered by these new display rooms very useful in bringing clients to a final decision in selecting lighting effects.

Fixture-Display Room, Central Electric Company, Chicago, Ill.

Holophane Arcs with Tungsten Lamps.

Official announcement is made by the engineering department of the National Electric Lamp Association that it is now safe and practicable to burn forty and sixty-watt tungsten lamps at an angle. This means that these lamps may now be used with the popular Holophane arc.

With characteristic conservatism the Holophane company has waited for official sanction from the lamp engineers before recommending this unit with tungsten lamps, although for many months it has been well known that these lamps could be so burned without danger. As long ago as last May an installation of thirteen No. 66 Holophane arcs was made in the "Knox Five and Ten Cent Store," in Bloomington, Ill. Three months later it was reported that not a single lamp had burned out, despite the fact that during one of the three months the lamps were in service two-thirds of the entire day, it being a very dark and rainy month. Similar installations were made by J. S. Maltman, of the Kankakee Electric Light Company, Kankakee, Ill., who states that he has had some twenty Holophane arcs equipped with sixty and 100-watt tungsten lamps in service for over three months. Mr. Maltman says, "We have not as yet found any trouble with the tungsten lamps burning at an angle, and I do not hesitate to recommend to our customers the burning of tungsten lamps in the Holophane arc."



Holophane Arc No. 66, with Brass Stem Support.

With the sanction of the engineering department of the National Electric Lamp Association and the favorable experience of its customers, the Holophane company is now recommending the Holophane arc for all classes of commercial services with tungsten lamps of the forty and sixty-watt sizes.

Daniels Boulevard Lighting System.

The accompanying illustrations show several units of the "Daniels Boulevard Lighting System"; a line of ornamental lighting specialties recently perfected and placed on the market by the Jandus Electric Company, Cleveland, Ohio. Although no attempt has been made to vigorously exploit the system, the interest manifested by electrical engineers, central stations, architects and civic federations has been most gratifying and confirms the manufacturer's belief that the boulevard lighting system has an important function to perform and that its establishment in the lighting field not only insures better illumination but heralds the disappearance of antiquated and barbaric productions in lighting fixtures.

Fig. 1.—Ionic Column, Showing Method of Attaching Lamp Mechanism.

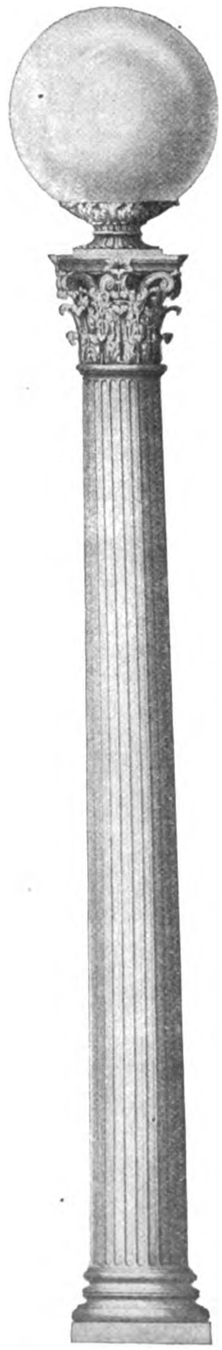


Fig. 2.—Column of Corinthian Design.

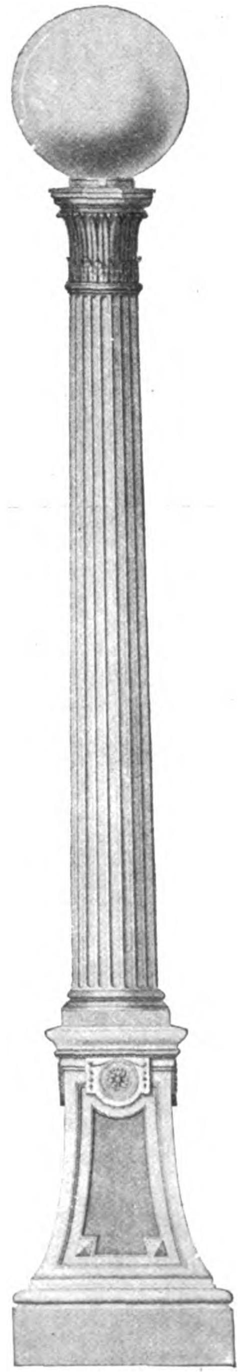

Fig. 3.—The "Billings Post."

Although arc lamps have been used for general illumination for thirty years, it is only recently that electrical engineers have devoted much time to the subject of art in the design of outdoor lighting fixtures. In their eagerness to produce apparatus having higher efficiency and greater mechanical strength they have overlooked to a marked degree the development of apparatus embodying artistic as well as utilitarian qualities, and have not fully appreciated the inherent possibilities of making outdoor lighting part of a general decorative scheme.

Each unit of the boulevard lighting system consists of a reinforced-concrete post, shaft and capital of classic design, surmounted by a complete arc-lamp mechanism enclosed within a twenty-inch opal glass globe. The post is ordinarily made of reinforced concrete and by proper mixture of ingredients can be made to correspond to sandstone, marble or granite. It is stated that the outfit complete sells for one-half the price of cast-iron; that it is indestructible, requires no painting and is more ornamental than cast-iron jib and goose-neck posts. Cast-iron, pressed-steel,

Fig. 4.—Boulevard Principle Adapted to Wall Brackets.

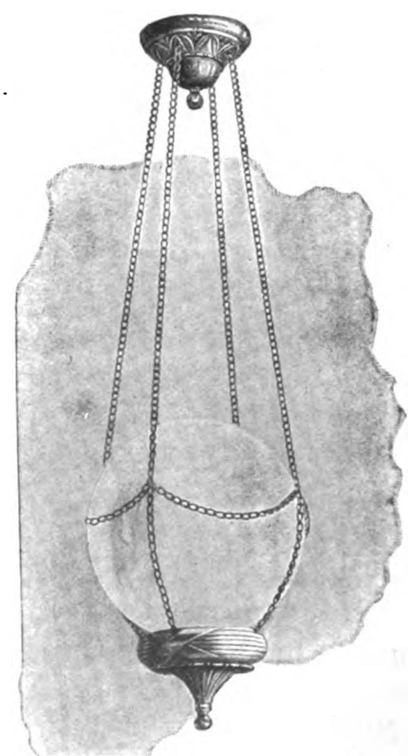

Fig. 5.—Jandus Ornamental Hanging Lamp.

copper or bronze posts are furnished when desired.

The lamp mechanism is somewhat shorter than the regular type of arc lamp

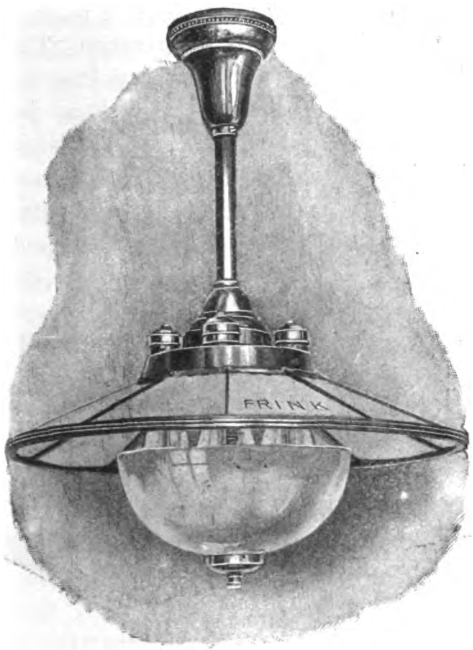

FIG. 1.—TUNGSTEN CLUSTER, WITH SILVER-PLATED, CORRUGATED GLASS REFLECTOR.

but allows the use of nine-inch upper and four-inch lower electrodes, thus insuring a life of 125 hours on multiple direct-current and alternating-current types and 100 hours on series direct-current and series alternating-current types. The use of the large globe insures perfect diffusion, entirely does away with uneven distribution of light due to the travel of the arc and produces a quality of light heretofore unequalled. The system must be seen in operation to be fully appreciated.

Fig. 1 shows the Ionic column and method of attaching the lamp mechanism thereto while Fig. 2 shows the Corinthian design. Fig. 3 shows the "Billings Post," designed by the J. L. Mott Iron Works, New York city, which is particularly attractive. The boulevard principle is applied to wall brackets as indicated by Fig. 4.

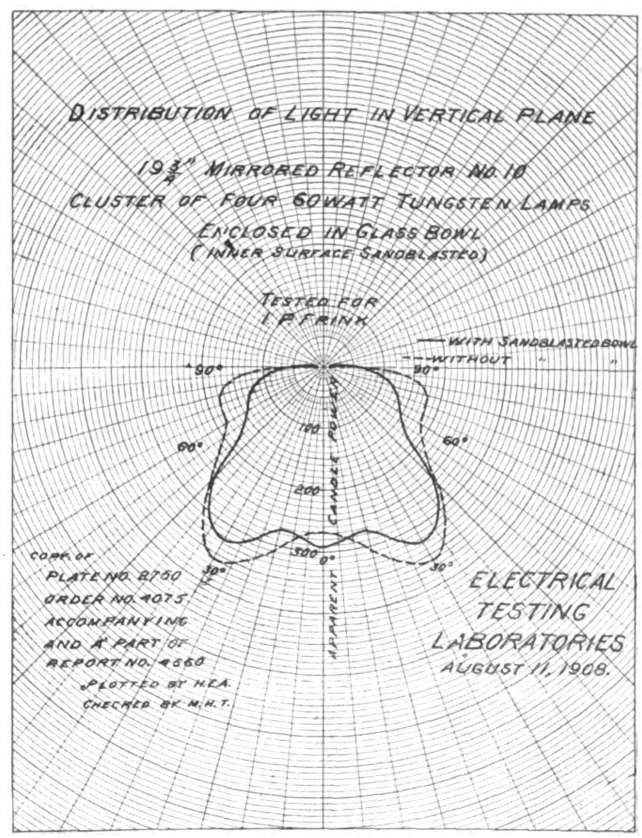
A modification of the types above described, the Jandus ornamental hanging lamp, is shown in Fig. 5. This type of arc lamp, designed particularly for store and other indoor lighting is something entirely novel and promises to be a popular specialty.

The lighting of boulevards, parks, public squares, public buildings, capitol grounds, business blocks, private drives, amusement parks and many other applications fall within the sphere of the boulevard lamp.

Frink Reflectors for Tungsten Lamps.

Coincident with the great improvement which has been brought about in the recently developed forms of metallic-filament incandescent lamps, manufacturers of reflecting mediums have shown a great deal of energy and ingenuity in devising auxiliaries which are adapted to utilize with the greatest advantage the increased illumination given by the new light sources. Prominent among the manufacturers of reflectors to create new designs for use with the tungsten lamp is the firm of I. P. Frink, 551 Pearl street, New York city. The accompanying illustrations show some of the most recent designs which this company has placed on the market.

These fixtures have been demonstrated by test to be very efficient for lighting stores, offices, public buildings and show windows generally. The utilization of these forms of reflectors with incandescent light sources is valuable, particularly because they eliminate shadows, there is no flickering, and no glare in the eye of the observer of the illuminated objects.



CURVES SHOWING DISTRIBUTION OF LIGHT IN VERTICAL PLANE, WITH MIRRORED REFLECTOR, SHOWN IN FIG. 1.

Fig. 1 shows a tungsten cluster, the reflecting medium of which is a mirror reflector with a spread of twenty inches and an over-all length of twenty-four inches. This is made in three, four or five-light combinations, for forty, sixty or 100-watt tungsten lamps. The inside of the reflector is lined with the Frink company's special silver-plated corrugated glass, and

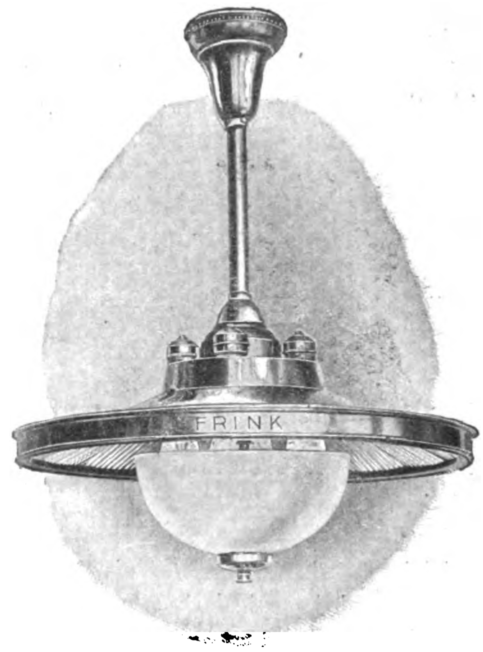


FIG. 2.—TUNGSTEN CLUSTER, WITH SPECIAL IMPORTED OPAL GLASS REFLECTOR.

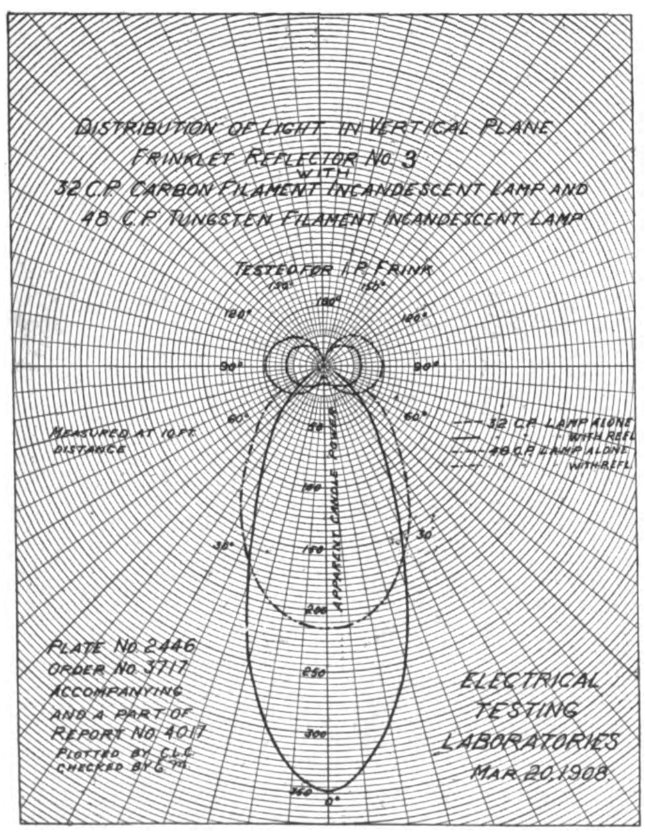
the lamps are surrounded by a hemispherical opalescent globe. This fixture is recommended by the company for the solution of problems in illumination where it is desired to give a maximum downward illumination. The accompanying curves, which have been made by the

Electrical Testing Laboratories, New York city, indicate the great increase in candle-power over the prescribed area which is brought about by the use of this reflector.

Fig. 2 is similar in its dimensions and equipment to the fixture shown in Fig. 1 with the exception that the reflecting medium is lined with the company's special imported opal glass. This fixture is recommended particularly where maximum downward illumination is not required, and where the illumination of the higher parts of the room is important.

Fig. 3.—For Lighting High Windows and Lighting Rooms from Above Glass Ceilings.

Fig. 3 shows a special reflector, twelve inches in diameter, which has thirty-two angles of reflection. This reflector, it is stated, will give 350 candle-power with an ordinary thirty-two-candle-power lamp, and is used for lighting high windows and for the illumination of rooms from above glass ceilings. It has proved very satisfactory for installations where a very great increase of candle-power over a prescribed area is desired. The accompanying curve shows the candle-power distribution of this reflector.



Curves Showing Distribution of Light in Vertical Plane with Mirrored Reflector Shown in Fig. 3.

Fig. 4 is another special reflector lined with the special silver-plated corrugated glass, and is adaptable for the illumination of show windows. From tests made by the company it has been demonstrated

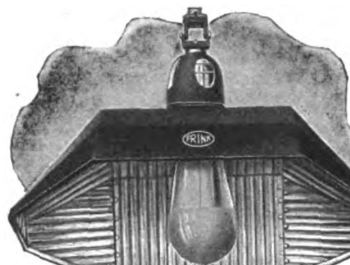


Fig. 4.—Special Window Reflector.

that these reflectors, spaced three feet apart, equipped with sixty-watt tungsten lamps, will give better results than three sixteen-candle-power carbon lamps spaced one foot apart, in ordinary reflectors—that is, there is a consumption of sixty watts, against 168 watts, or a saving of over sixty-five per cent.

Not only are these reflectors made in standard forms, such as are illustrated herewith, but the reflecting medium is of such a nature that special designs can be constructed to meet special requirements, and predetermined results secured with a high degree of accuracy.

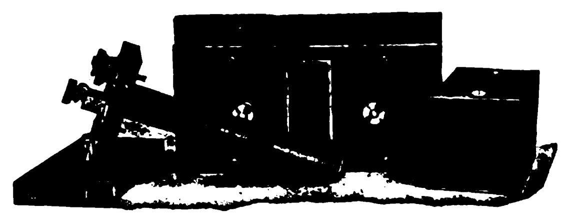
"Cartridge" Jump-Spark Coils.

The "Cartridge" jump-spark coils, manufactured by the Chicago Coil Company, 187 Jackson Boulevard, Chicago, Ill., represent several features of particular merit in spark-coil construction. The "Cartridge" coil derives its name from the fact that the condenser, as well as the secondary winding of the coil, can be replaced readily or reloaded. This is made possible in the "Cartridge" design without requiring the person handling the coil

Chicago Cartridge Coil Assembled.

to disconnect any wires. There are no spring nor screw connections interposed in the battery circuit.

The vibrator used on the "Cartridge" coil is so designed as to give the greatest speed possible, and is provided with contacts both on the armature and adjust-



Exploded View of Chicago Cartridge Coil.

ment screw, made of pure platinum alloyed with twenty-five per cent of iridium.

One of the important features of the "Cartridge" coil is the construction of its windings, both of which employ black enameled magnet wire. The secondary and primary windings of the coils have a layer of very high insulating paper, especially prepared, between each layer of wire. After the coils are wound and put into the containers, these containers are filled with special insulating compound and placed in a vacuum pan, where all air and moisture are withdrawn.

All spring connections on the secondary cartridge and condenser are made of German silver, and bear heavily against three corresponding contact buttons, so that a continuous circuit is maintained at all times.

The designer and patentee of the "Cartridge" coil is H. D. Stroud, for several years an electrical designer and engineer with the Western Electric Company.

Holophane D'Olier Metal Reflectors.

The Holophane Company, New York city, has acquired, and hereafter will have exclusive control of, the metal reflectors designed by, and manufactured under patents of, Henry D'Olier, Jr. It is the policy of the Holophane Company to maintain leadership in the field of illumination, and this policy has been expressed in the constant improvement of Holophane globes and reflectors.

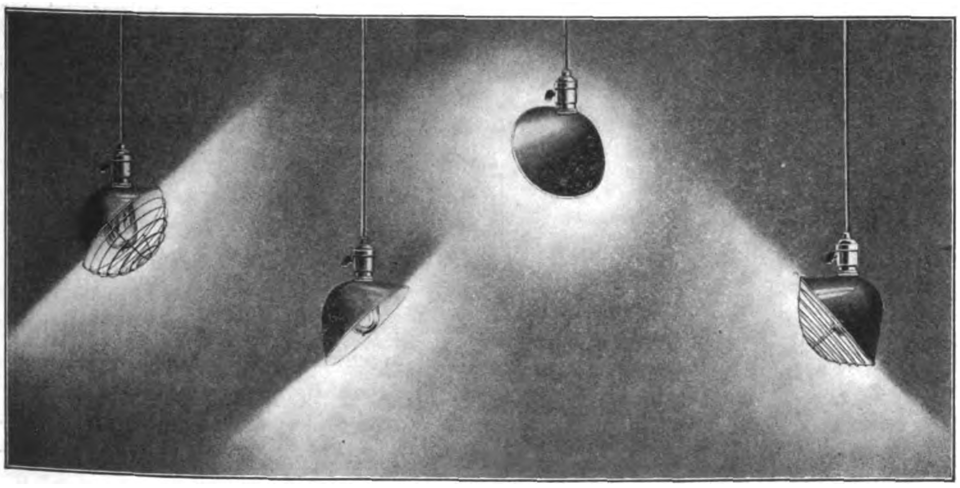
The addition of this line of metal reflectors is a further step in advance. Metal reflectors have a distinct place, and in industrial-plant lighting, in certain classes of display-window illumination, and in many cases where excess of dust and grime or liability to breakage is constant, the use of glassware is almost always inadvisable and frequently absurd.

With the Holophane D'Olier metal reflectors the company is prepared to furnish a line combining scientific design, high efficiency and extreme flexibility.

These metal reflectors are made in twenty-eight sizes and styles, and are furnished in four exterior finishes—brush brass, polished brass, oxidized copper and green enamel. The interior finish in all cases is a "satin aluminum," produced by a secret process, and giving a soft, well-diffused reflection of an almost pure white color.

These reflectors require no shade-holder, as each is provided with an attached clip spring holder reinforced with a heavy steel ring. This can be snapped onto any lamp socket, and while holding the reflector firmly, allows it to be easily rotated about the lamp, thus throwing the light in any desired direction.

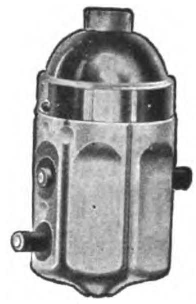
These reflectors are wrapped in waxed paper and packed individually in stout cartons. While they are practically indestructible when in service, they are not proof against rough handling and carelessness upon the part of clerks and stock boys. This is but one of the many innovations made by the Holophane Company when assuming control of the D'Olier reflectors.



Angle-Set Holophane D'Olier Metal Reflectors, With and Without Wire Guard.

A Two-Circuit Pendent Switch.

The Cutler-Hammer Manufacturing Company, Milwaukee, Wis., has placed on the market an elaboration of its push-button specialties which were described a few weeks ago. This is a new two-circuit porcelain pendent switch, and contains the same simple three-piece mechanism as the other push-button specialties. The accompanying illustration gives a good idea of the appearance of this device. The body of the switch is of porcelain, the cap of brass provided with a porcelain bushing.



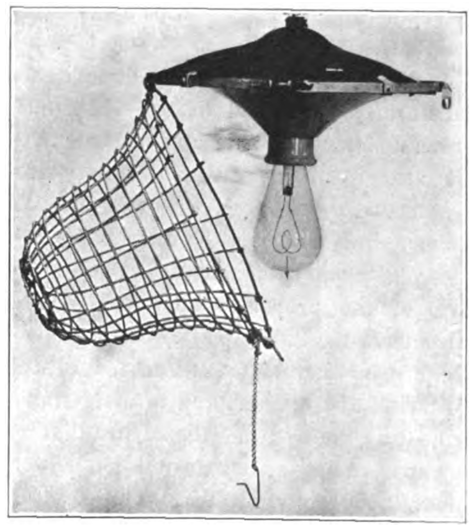
Cutler-Hammer Two-Circuit Porcelain Pendent Switch.

This two-circuit pendent switch will fill a long-felt want. A single one of these switches may be used to control two separate light circuits in any of the standard clusters, or to control two separate clusters of lights; or the switch may be so connected that one push-button controls the lights and the other push-button controls some other electrical device, such, for instance, as a fan. Many other applications of this two-circuit switch will readily occur to those familiar with electrical installations.

The Greenwood Adjustable Street-Lamp Guard.

The accompanying illustrations show the Greenwood adjustable street-lamp guard, made by the Greenwood Manufacturing and Supply Company, 141 Milk street, Boston, Mass. This lamp guard is composed of a flat metal band surrounding the hood, made in two distinct parts, with thumbscrews that allow the fastener to be adjusted from twelve to fifteen inches. The guard is hinged to the flat metal band on one side, and provided with a clasp fastener on the other, thus allowing it to swing when it is necessary to renew the lamp. The wires in the guard are of hard-drawn steel, and are laced with fine wires where they meet. The whole guard is galvanized and warranted not to rust.

Greenwood Adjustable Street-Lamp Guard.



Greenwood Adjustable Street-Lamp Guard, with Guard Down, for Lamp Trimming.

With the introduction of the high-priced, high-efficiency lamps, the electric lighting companies that are using this guard claim a great reduction in breakage. This guard fills a distinct place now that the companies are exercising the greatest possible care to insure long life to the newer types of incandescent lamps.

Air-Blast Transformers for the Calumet and Hecla Transmission System.

The accompanying illustration, Fig. 1, shows an installation of six 500-kilowatt Wagner air-blast transformers at one of the substations of the Calumet & Hecla Mining Company, Calumet, Mich., comprising part of an installation of 500-kilowatt, 2,300-13,200-volt, twenty-five-cycle and 370-kilowatt, 13,200-480-volt, twenty-five-cycle Wagner air-blast transformers, aggregating 10,830 kilowatts, that has been put into operation during the last few years.

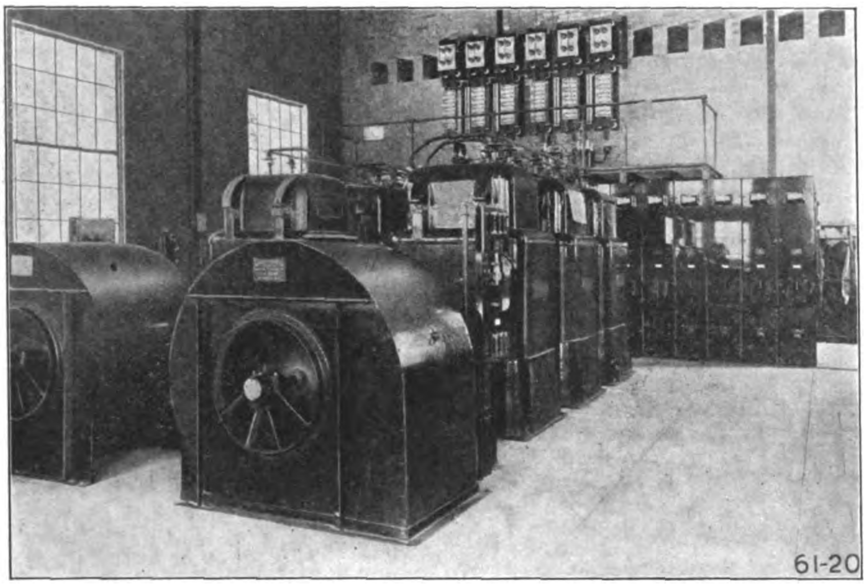


Fig. 1.—View in Calumet Substation, Showing Six of the Present Installation of Nine 500-Kilowatt Wagner Air-Blast Transformers.

The original installation of Wagner transformers consisted of the six transformers shown in Fig. 1 and of three 370-kilowatt, 13,200-480-volt, twenty-five-cycle transformers. In this transmission scheme, power is generated at 13,200 volts, three-phase, and transmitted to various parts of the property controlled by the Calumet & Hecla company. A large portion of the power is transmitted to the substation at Calumet, and is there transformed, by the first-mentioned installation of transformers, at a transmission potentiol of 2,300 volts for various uses about the mines, such as the operation of pumps, machine tool and crushers. Another large part of the power, involving the employment of both 370-kilowatt and 500-kilowatt transformers, is used in the vicinity of the generating station, for operating motors in the stamp-mills and smelters, and other above-ground apparatus; including about 1,500 kilowatts in a new mill that has recently been built about two thousand feet from the generating station.

The generating station is situated at Lake Linden, about seven miles from Calumet, on the property of the Calumet & Hecla Company adjacent to its stamp-mills and smelters.

The original installation proved so satisfactory that a duplicate order, plus an additional unit of 500 kilowatts, was given to the Wagner Electric and Manufacturing Company. Up to the present time the entire installation has worked very satisfactorily under difficult load conditions. Thus, one unusually severe condition has been in the frequent starting of the large motors that are employed on the circuits, which results in occasional extremely heavy overloads. Another feature that had to be guarded against in this installation was the frequent occurrence of severe electrical storms. The storm period in this region lasts throughout the summer months. The transformers were subjected to frequent lightning discharges, but have up to the present time successfully withstood these extraordinary conditions. In one instance the lightning succeeded in getting past the protective devices and into one of the trasformers, but fortunately did no damage beyond burning off a lead, owing to the excellence of the insulation. The transformer was repaired immediately and was put back into service within a few minutes after the occurrence of the discharge.

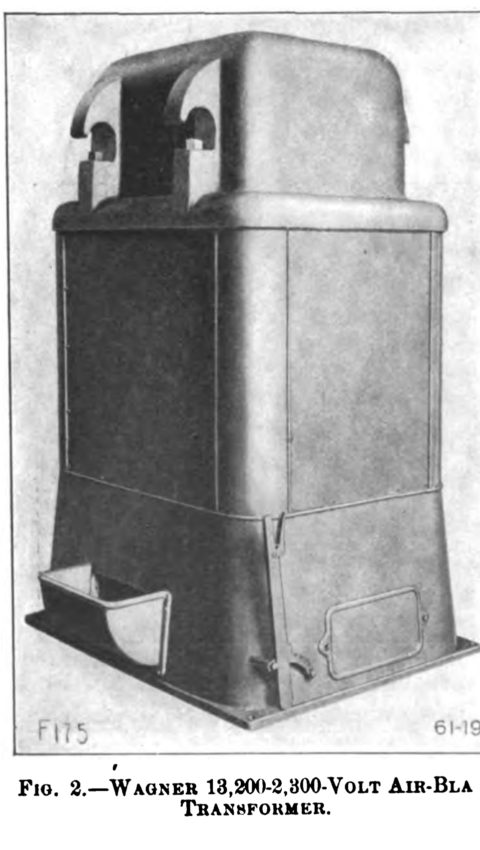

Fig. 2.—Wagner 13,200-2,300-Volt Air-Blast Transformer.

Fig. 1 shows six of the present installation of nine 500-kilowatt transformers in the Calumet substation. The two blowers, each of which is driven by a Wagner 440-volt, twenty-five-cycle, seven-and-one-half-horse-power induction motor, have an aggregate capacity adapted to take care of all of the transformers in the substation. The view also shows the low-tension distributing circuits, the portion of the switchboard comprising the 2,200-volt feeder-circuit equipment, the lightning arresters and the apertures in the wall for the admission of the conductors of the three-phase transmission line from the power station seven miles distant.

The construction of the Wagner air-blast transformer presents several interesting features. As shown in Fig. 2, which is a view of one of the 13,200-2,300-volt transformers above referred to, the air passages are so arranged that the air is taken in at the bottom of the coils, and after passing upward through the coils is forced by deflecting screens to pass downward around the iron circuit, and is then discharged by a separate passage through the base of the transformer.

The shutter in the base of the transformer may be so arranged that in the summer time the warm air may be discharged into an underground duct and during the winter out into the air of the substation for heating purposes.

The transformers are of the shell type, with pancake-coil windings giving maximum cooling surface, and at the same time the most favorable disposition of insulation between primary and secondary, and between coils and iron.

Current Electrical News

DOMESTIC AND EXPORT.

PROPOSED WESTERN POWER PLANT—A large electric light and power plant, costing $6,000,000, is soon to be erected near Marblemount, on the banks of the Skagit River, Wash. It is being financed by a syndicate of Denver (Col.) capitalists. The constructing engineer, with a corps of ten assistants, is on the ground. A track is to be built from Rockport to enable the builders to secure machinery and supplies.

TELEPHONE MERGER EFFECTED—It is announced that a company will be incorporated to lease the properties of the United States Telephone Company, the Cuyahoga Telephone Company, of Cleveland, Ohio, and the Citizens' Telephone Company, of Columbus, Ohio. Options have been taken on these properties by the new company. The United States Telephone Company, operating long-distance wires, is capitalized at about $4,000,000. It operates over 12,000 miles of long-distance wires, connecting 300,000 independent telephones, and controls nine local companies. The Cuyahoga company is capitalized at $3,000,000 and the Citizens', of Columbus, at $700,000.

INTERURBAN RAILROAD ORGANIZED—The Iowa Interstate Railway Company has been organized in Des Moines, Iowa, and officials, all well-known Des Moines men, elected. Articles of incorporation will be filed shortly. The proposed road is to be built from Council Bluffs to Muscatine by way of Des Moines. The promoters of the project state that the final arrangements for a working capital of $10,000,000 have been made. The portion between Des Moines and Council Bluffs will be built first. It will not run directly through Des Moines, but will run into the city from Springhill, by way of the army post. From Springhill the line will run west through Winterset, Greenfield, Fontanelle, Cumberland, Lewis and Oakland, and thence direct to Council Bluffs. The eastern section of the line, to be built later, will run almost due east from Springhill to Muscatine, *via* Indianola, Knoxville, Oskaloosa, Sigourney and Washington. It is stated by the promoters that work will be commenced at once and pushed to completion at the earliest date possible.

ELECTRIC LIGHTING.

REEDSVILLE, WIS.—The municipal light plant has been closed indefinitely. The plant cost about $15,000.

PIQUA, OHIO—L. A. Pearson, of West Milton, has been granted a twenty-year franchise and contract for furnishing the town with electric lights at his bid of $85 per arc lamp per year.

LITTLE ROCK, ARK.—Robert Crowe, of Arkadelphia, is in Nashville figuring on a proposition to establish an electric light plant at that place. The city council, it is said, is disposed to grant the franchise asked for by Mr. Crowe.

WILKES-BARRE, PA.—It is stated that the building of a large new electric power station in Lapland is shortly to be taken in hand. Either the Norr or Soderland Falls will be used. The power available is estimated at 88,000 horse-power.

BUTTE, MONT.—John D. Ryan and other new owners of the Great Falls Water and Power Company, supposed to represent Amalgamated interests, announce their intention to build a new dam on the river at Great Falls and develop 23,000 horse-power.

ANDOVER, N. B.—At a meeting of the members of the electric light district of Andover and Perth it was decided to install an electric light plant in this district at once and to enter into a contract with the New Brunswick & Maine Power Company to supply the power.

ISHPEMING, MICH.—A material enlargement of its water-power plant at Quinnesee Falls, on the Menominee River, is planned by the United States Steel Corporation. It is proposed to use the power for the operation of the machinery at the Aragon property at Norway also.

KIRKLAND, WASH.—A franchise has been granted by the council authorizing the Kirkland Light and Power Company to furnish electric light to this town and the adjoining neighborhood. James Bell and T. L. Kiler are behind the project. The company plans to begin work at once.

TOPPENISH, WASH.—Material is arriving for the electric light and power plant of the Reservation Electric Light Company. The managers are A. H. Campbell and M. Kramer, recently of Seattle. They expect to give a twenty-four-hour service and to have the plant in operation by November 1.

PLATTEVILLE, WIS.—It is said that the Fox interests, which recently purchased Galena's municipal plant, expect to be ready to furnish power and commercial lighting within three months. Eventually they will build a power plant capable of furnishing electrical power for all the mines in the district.

LINDEN, ALA.—A move is now on foot to supply Linden with electric lights. Plans are being perfected whereby J. A. Johnson and his brother, O. A. Johnson, will be granted permission by the city council of Linden to erect, equip and maintain an electric light plant sufficient to furnish at least 800 electric lights.

CHARLOTTE, N. C.—The Southern Power Company has placed an order with Milliken Brothers, of New York, for 2,000 steel towers, at a cost of $250,000. These towers will carry 100,000-volt lines. The company will let another contract representing an expenditure of about $60,000 for the Loray Cotton Mill at Gastonia, N. C.

MACUNGIE, PA.—Macungie will have an electric light and power company. An organization is now being formed, and, it is stated, will start operations as soon as a charter is granted. It is also stated that Slatedale, in Washington Township, will have an electric light and power company. The town has a population of 1,200.

BALLINGER, TEX.—Representatives of an eastern company have made application for a franchise to establish and maintain in Ballinger an electric light and power plant. Ballinger already has a light plant. The new company proposes to furnish the city free of cost ten arc lights and to give service at a rate ten per cent below the present rate.

AUSTIN, TEX.—The Water, Light and Power Commissioners will receive bids until September 19 for constructing a reinforced concrete addition to the municipal pumping station, approximately eighty-nine by sixty-four by thirty-five feet. For specifications, blank forms and other information address Walter G. Kirkpatrick, engineer, Jackson, Miss., or the Water, Light and Power Commissioners, Austin, Tex.

BOONTON, N. J.—Papers of incorporation of the Boonton Electric Company have been filed in the Morris County clerk's office. It is understood that the new company has or shortly will take over the Public Service plant in Boonton on a lease. The authorized capital stock is $100,000, of which $1,000 is paid in. Senator Thomas J. Hillery has eight shares and is the agent in charge. Other incorporators are John J. Hillery and Anna Hillery.

PRESCOTT, ARIZ.—Similar to the work now being done by the Arizona Power Company at Fossil Creek are the plans of the Verde River Power Company, which, at a point four miles below the mouth of Fossil Creek, is preparing to develop 2,500 horse-power by damming the Verde at a point where a considerable fall can be secured. The dam will be in the vicinity of Bloody Basin, in one of the roughest parts of Arizona. The estimated cost of the plant and transmission lines is $400,000.

ALBANY, N. Y.—The Public Service Commission, Second District, has denied the application of the Hudson River Water Power Company for authority to issue $62,000 first mortgage bonds; also the application of the Hudson River Electric Company for consent to transfer to the Hudson River Water Power Company the electric power transmission line running from Ballston Spa to Alplaus, and for authority to acquire $51,000 bonds of the Hudson River Water Power Company in payment therefor.

AUBURN, N. Y.—With an expenditure of approximately $30,000, the Auburn Light, Heat and Power Company contemplates duplicating its present equipment at the North street power-house. Plans for the new work are now ready and the individual contracts will soon be let. The company intends to increase its lighting facilities to correspond with the increased demand for power. Superintendent M. Curry Turpin stated that work on the alterations of the plant will commence soon. It is expected that about four months will be required to make the changes.

EL PASO, TEX.—E. Krause and W. E. Fletcher, of this city, have bought up the water rights along the Penasco River, in the Sacramento Mountains north of El Paso, and will divert the waters of the river into a canal, then into Cox Cañon, near Mayhill, N. M., and from the power thus generated distribute electric current throughout this section of the country. They claim that they will distribute current in El Paso at one and one-half cents per horsepower-hour, and that there will be sufficient to supply Alamogordo, Cloudcroft, Orogrande and other New Mexico towns, in addition to this city. It will take $500,000 to finance the deal, and it is stated that actual construction work will be under way in eight months.

JESSUP, PA.—Jessup has formed a stock company which will construct a modern electric light plant to supply current for street and commercial purposes. The company is capitalized at $25,000, and a ten-year contract has been made with the borough council for fifty street arc lights. The stock has been nearly all subscribed for by local people. The officers are: President, J. J. Sweeney; secretary, B. J. McGurl; treasurer, W. G. Robertson. The contract for the construction of the plant has been awarded to the Scranton Electrical Construction Company, of Scranton. The building will be of brick. The board of directors comprise: Rev. J. M. Smauler, W. G. Robertson, J. H. Hemelright, C. P. Ford, J. J. Sweeney, B. J. Cummings, A. J. Smalco, John Forini, John Slwka, H. V. Lawler and B. J. McGurl.

ALBANY, N. Y.—The Public Service Commission, Second District, has granted the application of the Madison County Gas and Electric Company for consent to issue $45,000 in gold bonds under a first consolidated mortgage. The order is made conditional that the bonds be sold at not less than eighty, and that the capital secured from the sale of the bonds be devoted to and used for the construction of a 60,000-volt transmission line from the steam plant of the Madison County Gas and Electric Company in Oneida to Oneida Castle and for the purchase of the necessary right of way therefor and installation in Oneida of a proper generator and the necessary instruments and appliances, for putting in proper repair an overhead system of the Madison County Gas and Electric Company in Oneida, and changing a part of the system from sixty to forty cycles.

ALBANY, N. Y.—The Public Service Commission, Second District, recently gave a hearing upon the application of the Newburgh Light, Heat and Power Company for permission to issue convertible debenture bonds in the aggregate sum of $350,000. The commission on April 29 issued its order authorizing the issue of eight per cent debenture bonds of the aggregate par value of $330,000. Since the granting of the order the company has taken up a new proposition whereby it is to take over the properties of the Hudson Counties Gas and Electric Company for the supply of electric current generated at Honk Falls on condition that the transmission line be constructed from the generating station in the city of Newburgh through the towns of Newburgh, Marlborough, Lloyd and New Paltz and the station of the Honk Falls Power Company at High Falls on Rondout Creek, and for that reason it has abandoned its proposition to erect a new steam power electric generating station in Newburgh.

ELECTRIC RAILWAYS.

TOLEDO, OHIO—The Toledo, Ann Arbor & Detroit electric line is to be offered for sale by order of the special master in chancery under mortgage foreclosure decree on October 12, at Monroe, Mich.

PHILADELPHIA, PA.—The J. G. Brill Company has received an order for seventy-five pay-as-you-enter cars from the New York City Railway Company. The cars are to be delivered as soon as possible.

CHICAGO, ILL.—The Aurora & Rockford Electric Company is being reorganized. The American Trust and Savings Bank has filed a petition to foreclose the $750,000 mortgage. Two receivers have been appointed.

FREDERICKSBURG, VA.—The preliminary survey for the West Point-Urbanna electric line has been completed. The route surveyed is from Chain Ferry to Saluda, thence across to Urbanna, near Oakes Landing. It is eighteen miles long.

MILWAUKEE, WIS.—Cars are now running from Milwaukee to Cedar Grove over the Milwaukee-Northern road. Cedar Grove is fifteen miles from Port Washington, the present terminus. The extension is being pushed rapidly from Port Washington to Sheboygan.

EASTON, PA.—The promoters of the proposed trolley line to connect the Easton & Washington traction line with Hackettstown and also construct another branch by way of Netcong to Newton say the necessary capital has been subscribed and that the lines will cost $1,000,000.

LANSING, MICH.—Articles of incorporation of the Saginaw & Flint Railway, capital $100,000, have been filed with the secretary of state. The company proposes to connect the two cities with an electric line and also run a branch to Vassar. Alexander Groesbeck, Nelson A. Taber and Mark Mitshkun are the incorporators.

LAPORTE, IND.—The Chicago, South Bend & Northern Indiana Railway has finished the construction of the Laporte extension of the line running west from South Bend. The opening of the road gives South Bend another outlet to the lake, and will connect Laporte and Michigan City with Elkhart, Goshen and Warsaw.

TACOMA, WASH.—Announcement is made by Manager E. J. Felt that the Pacific Traction Company expects to be in a position soon to complete the construction of the extensive street-car system in Tacoma it had heretofore planned. In addition to the line it now has in operation to American Lake the company has franchises for routes covering almost the entire city.

MILWAUKEE, WIS.—The petition of the Milwaukee Light, Heat and Traction Company for a certificate of convenience and necessity for an electric railway line to Hartford, in Washington County, will be heard by the Railroad Rate Commission in Madison, September 17. The proposed line is to run on Fond du Lac road through the towns of Granville, Menominee, Richfield and Polk.

STREATOR, ILL.—Actual construction work on the Chicago, Ottawa & Peoria interurban line between Grand Ridge and this city will be started shortly. D. McAfee, the company's representative, is engaged in arranging the final details for the starting of the work. It is now the intention to start building in this city and push the work as rapidly as possible until it has been completed to Grand Ridge.

FINDLAY, OHIO—Citizens of this place met with the projectors of the Findlay & Marion electric line and agreed to undertake the work of raising $125,000 necessary for the road's financiering. A like amount will be raised by Marion citizens. Already $800,000 worth of bonds has been sold to eastern parties. It is thought that work on the construction of the road will begin at once. It will be forty-eight miles long.

NEW YORK, N. Y.—Operations are to be begun at once on the construction of a double-track trolley line from Flushing to Bayside and Whitestone. The road will be five miles long, and will open for development much new territory along the north shore of Long Island. The franchise under which these improvements will be made was granted to the New York & Queens County Railway Company recently.

PERSONAL MENTION.

MR. FRANK B. KNIGHT, of Dallas, Tex., one of the pioneer telephone men of the United States, is renewing old-time friendships in New York city this week.

MR. VINCENT GRAY, formerly with the Columbia Incandescent Lamp Company, in charge of the Illinois district, has accepted a connection with the Westinghouse Electric and Manufacturing Company, and will have charge of the lamps, detail and supply business of the Milwaukee sub-district office.

MR. WILLIAM H. McKINLOCK, president of the Metropolitan Electrical Supply Company, Chicago, has been spending some days in New York city among old electrical friends and also visiting C. Edward Murray, of the Crescent Insulated Wire and Cable Company at his summer home at Sea Girt, N. J.

MR. EARLE T. HOBART, of Brookline, Mass., has started for San Francisco, whence he will sail for China the latter part of September under a three years' engagement with the College of Science at Pekin, China. He will establish and equip a department of electricity in connection with this institution, and the department will be the first of its kind in China. Mr. Hobart was graduated from the Brookline High School in 1904, at the age of eighteen, and from the department of mechanical and electrical engineering of Cornell University last June. In July he entered the employ of the General Electric Company at Lynn, Mass., and two weeks later received the appointment to China.

MR. R. F. MORRIS, who for a number of years has been manager of the Richmond (Va.) exchange of the Southern Bell Telephone and Telegraph Company of Virginia, resigned on September 1. Albert S. Tanner, long connected with the company at Richmond and other points, will succeed Mr. Morris as manager of the Richmond exchange. Mr. C. W. Connors, manager of the Opelika (Ala.) office of the Southern Bell Telephone and Telegraph Company, has been transferred to the commercial department of the company at Montgomery, Ala. He is succeeded by W. E. Bare, who has been manager at Alexander City. Mr. Robert M. McCandlish has been placed in charge of the Hampton and Newport News (Va.) exchanges. Spencer Henley, who has been in charge of the Newport News office, has been transferred to Lynchburg, Va.

MR. P. S. MUELLER has opened an office in the Electric Building, Cleveland, Ohio, as a general selling agent, where he will keep open house and be pleased to meet his old friends and patrons in the electrical field. Mr. Mueller was graduated from the electrical course of the University of Nebraska in 1898, and shortly afterward entered the telephone switchboard shops of the Western Electric Company, Chicago. He spent two years in the shops and in telephone installation work and on the road. The two years following he was connected with the Chicago office of the Westinghouse Electric and Manufacturing Company, but decided to go back into the telephone business, and in the fall of 1902 entered the employ of the Kellogg Switchboard and Supply Company. He was in the publicity department of this company, and for a short time had charge of the Philadelphia and Cleveland offices. Mr. Mueller will represent in Ohio and West Virginia the following firms: Alfred F. Moore, Philadelphia, manufacturer of insulated wires and cables and all sorts of telephone cordage; the Stackpole Battery Company, St. Marys, Pa., manufacturers of dry cells and carbon products; the Warner-Newton Lumber Company, Grand Rapids, Mich., producers of cedar poles and posts; the Yesbera Manufacturing Company, Toledo, Ohio, builders of telephone booths; the General Insulate and Machine Company, Brooklyn, N. Y., manufacturers of receiver shells and other hard-rubber substitutes.

OBITUARY NOTE.

MR. B. F. ELLISON, for eight years general manager of the Superior Water, Light and Power Company, Superior, Wis., died on September 1 at the home of his brother-in-law at St. Paul, Minn., from a complication of diseases. Mr. Ellison had been ill for some time, and his death was not unexpected. He was born at Utica, N. Y., fifty-five years ago, and previous to his connection with the Superior Water, Light and Power Company was associated with the St. Paul (Minn.) Gas Light Company. He is survived by a widow and four children.

ELECTRICAL SECURITIES.

During the short week the stock market witnessed a somewhat irregular decline, with trading moderately active, and largely professional. Professional sentiment appears to be decidedly bearish, and there was little brought out in the way of news or events to stimulate bull activity. The outcome of the Vermont election, which is generally considered to predict a Republican victory in November, had a hopeful influence on the stock market, while the report of the American Smelting interests had a most depressing tendency. It appears that these stocks, instead of being held by a few strong interests, are widely scattered, with little or no coherence in any endeavor to maintain prices at what appears to be their intrinsic position. There is beginning to be some apprehension concerning the outcome of the crops which are about to be harvested. Disappointing reports have come to hand, and while the yield will be as large as even in record years, it is not apparent that there will be any very great surplus to dispose of abroad. This condition, however, may be greatly changed in favor of the agriculturists before the next report is due.

Dividends have been declared upon the following electrical securities: Chicago City Railway Company; regular quarterly dividend of 1½ per cent, payable September 30 to stock of record September 14. Philadelphia Traction Company; regular semiannual dividend of $2 per share, payable October 1 to stock of record September 5. Interborough Rapid Transit Company; regular quarterly dividend of 2¼ per cent, payable October 1 to holders of stock and voting trust certificates of record September 14. Canadian General Electric Company, Limited; quarterly dividend of 1¾ per cent on the common stock for the three months ended September 30, and a semiannual dividend of 3½ per cent on the preferred stock for the six months ended September 30, both dividends payable October 1.

ELECTRICAL SECURITIES FOR THE WEEK ENDED SEPTEMBER 5.

NEW INCORPORATIONS.

BURLINGTON, VT.—Cory-Deavitt-Frost Electrical Company. $150,000. Incorporators: F. M. Corry, E. H. Deavitt, I. M. Frost, L. D. Taft and W. T. Dewey.

GALION, OHIO—Marion & Galion Electric Railway Company. $10,000. To build an electric road between Marion and Galion. Incorporators: F. H. Murphy, of Cleveland, Ohio, and others.

COLUMBUS, OHIO—Springfield Light, Power and Heat Company, Springfield. $1,000,000. Incorporators: Joshua D. Price, W. W. Keifer, W. H. Sharp, C. S. Kay, L. M. Ferguson, F. M. Hagan.

TELEPHONE AND TELEGRAPH.

BURLINGTON, VT.—The directors of the Orange County Telephone Company have decided to build a trunk line from East Montpelier to Plainfield.

MUNCIE, IND.—The Home Telephone Company, of Gaston, has completed and placed in operation its system. The company is composed of residents of Gaston.

MAYSVILLE, KY.—J. D. Powers has been appointed receiver for the Central Home Telephone Company, of Louisville, by Judge Cochran, of the United States District Court. The company owns many long-distance lines.

TUCSON, ARIZ.—The Arizona Overland Telephone Company now has its line in operation from Roosevelt to Fossil Creek, where it will be connected with the line from Flagstaff. It is the intention to incorporate the Fossil-Flagstaff line into the Overland, thus bringing it under one management. That accomplished, the new company contemplates getting control of the line between Globe and Mesa.

SALT LAKE CITY, UTAH—Connection by the Utah-Nevada & Idaho Telephone Company with Nevada-Salt Lake points has been completed. This is the first link in the system which will ultimately connect Salt Lake with San Francisco and Los Angeles. The crews have been laid off with the completion of this 211-mile line, and work will be resumed at Shafter in September for the completion of the line to Ely. The opening of the line to Wells gives telephone connection with all of Elko County, furnishing direct conection with Elko, Deeth, Tuscarora, and as far north as the Duck Valley Indian reservation, leaving a gap of less than thirty miles to be constructed in order to secure communication with Gold Circle, Golconda and Winnemucca, at which points the company is already operating telephone plants. Arrangements are being made for taking over the system at Pioche, with the radiating toll lines. It is the company's intention to build as quickly as possible between Ely and Pioche, which will bring this southern system of telephones in direct communication with Salt Lake City.

INDUSTRIAL ITEMS.

THE NOVELTY INCANDESCENT LAMP COMPANY, Emporium, Pa., is issuing a pretty calendar card for September.

HARVEY HUBBELL, Bridgeport, Ct., has ready for distribution some attractive literature devoted to the Hubbell pull socket and Hubbell attachment plugs for electric fans and fixtures.

THE DALE COMPANY, Ninth avenue and Hudson street, New York city, has published a neat booklet devoted to the Dale designs for tungsten lamps. Copies of this booklet will be furnished upon request.

THE ECONOMY ELECTRIC COMPANY, Warren, Ohio, is making some very attractive announcements concerning its large supply of renewed lamps. The company offers a 3.1-watt lamp at an extremely low figure.

THE M. W. DUNTON COMPANY, 65 Atlantic avenue, Providence, R. I., announces a new line of special friction tape which will be known as the "Black Diamond." A free sample of this tape will be sent upon application.

THE BRUNSWICK REFRIGERATING COMPANY, New Brunswick, N. J., will be pleased to send to those interested upon request some new literature devoted to refrigeration in model homes, and general data concerning refrigerating apparatus.

D. C. & WILLIAM B. JACKSON announce that they have moved their western office from Madison, Wis., to the Commercial National Bank Building, Chicago, Ill., and that Mr. William J. Crumpton will be in immediate charge of the Chicago office.

THE CROCKER-WHEELER COMPANY, Ampere, N. J., has opened a new office in the Gumbel Building, Kansas City, Mo., for the sale of Crocker-Wheeler motors, dynamos, transformers, switchboards, etc. The office is in charge of A. W. Paine.

THE WHEELER CONDENSER AND ENGINEERING COMPANY, West Street Building, New York city, has ready for distribution bulletins describing the Edwards patent air-pumps and the company's products and facilities. Copies of these bulletins will be furnished to those interested upon request.

THE NERNST LAMP COMPANY, Pittsburg, Pa., has published a handsome catalogue describing and illustrating the Westinghouse Nernst lamp. This catalogue is of particular interest at this time, as an entirely new unit, and one which will prove a decided factor in lighting conditions, is described. A comparative table of Westinghouse Nernst and other electric lamps introduces some very interesting figures.

THE EMERSON ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., is distributing bulletin No. 3,135, devoted to single-phase induction motors, frame 32DD, one-tenth, one-eighth and one-sixth horse-power, light-load start, for intermittent service; bulletin No. 3,706, devoted to electric buffing lathes for alternating and direct current; bulletin No. 3,958, devoted to motors for family washing machines.

THE AMERICAN CIRCULAR LOOM COMPANY, Boston, Mass., announces that its new factory at North Cambridge, Mass., is now in full operation, and that all orders for "Circular Loom" will be filled promptly. The factory is equipped with the most modern and improved machinery, and the company states that the high standard hitherto set in the manufacture of its product will not only be maintained, but will be heightened by new methods.

THE METROPOLITAN ENGINEERING COMPANY, New York city, on the occasion of the Sherman notification celebration at Utica, N. Y., recently, lent to the Utica Gas and Electric Company a sign constructed of eighteen-inch "Attraction" letters containing 400 sixteen-candle-power lamps. The sign produced the illuminated word "Welcome" on both sides. This is a feature of the Metropolitan company's business that is frequently called for by central stations in every part of the country.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., reports that its incandescent lamp sales for the first half of the present year are more than double its sales for the corresponding period of 1907. This condition of affairs is attributed partly to the fact that the company carries in Chicago, for immediate shipment, a large stock, in all standard voltages and candle-powers, of high-efficiency units, such as Columbia tungsten and tantalum lamps, as well as Columbia carbon-filament lamps, and due also to the excellent quality of the Columbia products.

THE WESTON ELECTRICAL INSTRUMENT COMPANY, Waverly Park, Newark, N. J., has issued circular No. 7, descriptive of new Weston instruments for both alternating and direct currents. This is divided into three parts. Part 1 describes and illustrates switchboard and alternating-current ammeters and voltmeters in two sizes, models 151 and 156; part 2, portable alternating-current ammeters, milli-ammeters and voltmeters, model 155, and part 3, "Eclipse" direct-current switchboard instruments of the electromagnetic type, models 159 and 160. The company will be pleased to send this circular upon request to any one interested.

THE EDISON MANUFACTURING COMPANY, Orange, N. J., announces that it has acquired the business of the Battery Supplies Company, of Newark, N. J., manufacturer of the Gladstone-Lalande battery and the BSCO battery, together with all patents, rights, etc., appertaining to the manufacture of these batteries. The name of the Battery Supplies Company has been discontinued and that company merged with the Edison Manufacturing Company. As the Gladstone battery elements were designed to be interchangeable with the Edison types, the Gladstone-Lalande battery will be retired, and sales or renewals of the Gladstone-Lalande battery will hereafter be ordered by the Edison types. The Edison Manufacturing Company will continue to make the BSCO 350-ampere-hour cell for railroad work, and, in addition, the same type of cell with special low-temperature electrolyte for the same class of work at points where low temperatures affect the ordinary sodium-hydrate electrolyte. This battery will also be manufactured in the 200-ampere-hour size, in two different styles, one with a liquid-tight, steel-enameled jar for portable engines and marine engines used on fresh water; the other with a liquid-tight porcelain jar for use on launches running in salt water and on stationary engines.

Directory of Electrical and Allied Engineering and Scientific Societies.

(Published in the Second Issue of Each Month.)

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. Secretary, L. O. Howard, Cosmos Club, Washington, D. C.

AMERICAN ELECTROCHEMICAL SOCIETY. Secretary, Dr. J. W. Richards, Bethlehem, Pa. Fall meeting, New York city, October 30-31.

AMERICAN ELECTROTHERAPEUTIC ASSOCIATION. Secretary, Dr. Albert C. Geyser, 352 Willis avenue, New York city.

AMERICAN FOUNDRYMEN'S ASSOCIATION. Secretary, Dr. Richard Moldenke, Watchung, N. J.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Secretary, Ralph W. Pope, Engineering Societies Building, 29 West Thirty-ninth street, New York city.

AMERICAN MATHEMATICAL SOCIETY. Secretary, F. N. Cole, 50 West 116th street, New York city.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION. Secretary, J. W. Taylor, Old Colony Building, Chicago, Ill.

AMERICAN ROENTGEN RAY SOCIETY. Secretary, Dr. G. C. Johnson, 514 Bijou Building, Pittsburg, Pa.

AMERICAN SOCIETY FOR TESTING MATERIALS. Secretary, Professor Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF CIVIL ENGINEERS. Secretary, Charles Warren Hunt, 220 West Fifty-seventh street, New York city.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Secretary, Calvin W. Rice, 29 West Thirty-ninth street, New York city.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS. Secretary, A. P. Folwell, 239 West Thirty-ninth street, New York city. Annual meeting, Atlantic City, N. J., October 20-23.

AMERICAN STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, B. V. Swenson, Engineering Societies Building, 29 West Thirty-ninth street, New York city. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY ACCOUNTANTS' ASSOCIATION. Secretary, Elmer M. White, treasurer Birmingham Railway, Light and Power Company, Birmingham, Ala. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY CLAIM AGENTS' ASSOCIATION. Secretary, B. B. Davis, claim agent Columbus Railway and Light Company, Columbus, Ohio. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY ENGINEERING ASSOCIATION. Secretary, J. W. Corning, electrical engineer Boston Elevated Railway Company, Boston, Mass. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY MANUFACTURERS' ASSOCIATION. Secretary, George B. Keegan, 2321 Park Row Building, New York city. Annual convention, Atlantic City, N. J., October 12-16.

ARKANSAS ASSOCIATION OF PUBLIC UTILITIES OPERATORS. Secretary, J. E. Cowles, superintendent of lighting Hot Springs Light and Railway Company, Hot Springs, Ark. First annual convention, Little Rock, Ark., September 17-18.

ARKANSAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES. Secretary, W. W. Freeman, vice-president and general manager Edison Electric Illuminating Company, Brooklyn, N. Y. Annual meeting, Lenox, Mass., September 15-17.

ASSOCIATION OF ELECTRIC LIGHTING ENGINEERS OF NEW ENGLAND. Secretary, Welles E. Holmes, 308 Washington street, Newton, Mass.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS. Secretary, P. W. Drew, Wisconsin Central Railway, Milwaukee, Wis.

CALIFORNIA ELECTRIC RAILWAY ASSOCIATION. Secretary, L. E. W. Pioda, Oak and Broderick streets, San Francisco, Cal.

CALIFORNIA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, P. T. Whittier, Spencer, Cal.

CANADIAN ELECTRICAL ASSOCIATION. Secretary, T. S. Young, Toronto, Canada.

CANADIAN STREET RAILWAY ASSOCIATION. Secretary, Acton Burrows, 33 Melinda street, Toronto, Ontario.

CENTRAL ELECTRIC RAILWAY ASSOCIATION. Secretary, W. F. Milholland, secretary and treasurer Indianapolis Traction and Terminal Company, Indianapolis, Ind.

COLORADO ELECTRIC LIGHT, POWER AND RAILWAY ASSOCIATION. Secretary, J. F. Dostal, Denver, Col. Annual convention, Glenwood Springs, Col., September 16-18.

CONNECTICUT STATE STREET RAILWAY ASSOCIATION. Secretary, F. W. Poole, Bridgeport, Ct.

ELECTRIC CLUB OF CLEVELAND. Secretary, George L. Crosby, 1200 Schofield Building, Cleveland, Ohio.

ELECTRICAL CONTRACTORS' ASSOCIATION OF NEW YORK STATE. Secretary, John P. Faure, 77 Water street, Ossining, N. Y.

ELECTRICAL CONTRACTORS' ASSOCIATION OF STATE OF MISSOURI. Secretary, Charles J. Sutter, 1220 Pine street, St. Louis, Mo.

ELECTRICAL TRADES ASSOCIATION OF CHICAGO. Secretary, Frederic P. Vose, Marquette Building, Chicago.

ELECTRICAL TRADES ASSOCIATION OF PHILADELPHIA, Secretary, E. A. Symmes, 810 Drexel Building, Philadelphia, Pa. Meetings, second and fourth Thursdays of each month.

ELECTRICAL TRADES ASSOCIATION OF CANADA, LIMITED. Secretary, William R. Stanley, Royal Insurance Building, Montreal, Canada.

ELECTRICAL TRADES ASSOCIATION OF THE PACIFIC COAST. Secretary, Albert H. Elliott, Claus Spreckels Building, San Francisco, Cal. Monthly meetings, San Francisco, first Thursday of each month.

ELECTRICAL TRADES SOCIETY OF NEW YORK (Member National Electrical Trades Association). Secretary, Franz Neilson, 80 Wall street, New York city. Board of directors meets second Friday of each month.

EMPIRE STATE GAS AND ELECTRIC ASSOCIATION. Secretary, Charles H. B. Chapin, 154 Nassau street, New York city.

ENGINEERS' CLUB OF PHILADELPHIA. Secretary, H. G. Perring, 1317 Spruce street, Philadelphia, Pa.

ENGINE BUILDERS' ASSOCIATION OF THE UNITED STATES. Secretary, J. I. Lyle, 39 Cortlandt street, New York city.

ILLINOIS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. A. Camp, Henry, Ill.

ILLINOIS STATE ELECTRICAL ASSOCIATION. Secretary, H. E. Chubbuck, La Salle, Ill.

ILLUMINATING ENGINEERING SOCIETY. Secretary, Van Rensselaer Lansingh, Engineering Societies Building, 33 West Thirty-ninth street, New York city. Annual convention, Philadelphia, Pa., October 5-6.

INDEPENDENT TELEPHONE ASSOCIATION OF TEXAS AND LOUISIANA. Secretary, C. A. Shock, Sherman, Tex.

INDIANA ELECTRIC RAILWAY ASSOCIATION. Secretary, P. H. White, Indianapolis, Ind. Monthly meetings, second Tuesday of each month.

INDIANA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. S. Norton, Indianapolis, Ind.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS. Secretary, Frank P. Foster, Corning, N. Y.

INTERNATIONAL INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. B. Ward, Grand Rapids, Mich. Secretary's office, Monadnock Building, Chicago, Ill.

IOWA ELECTRICAL ASSOCIATION. Secretary, W. N. Keiser, Des Moines, Iowa.

IOWA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. C. Deering, Boone, Iowa.

IOWA STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, L. D. Mathes, Dubuque, Iowa.

KANSAS GAS, WATER, ELECTRIC LIGHT AND STREET RAILWAY ASSOCIATION. Secretary, James D. Nicholson, Newton, Kan. Annual meeting, Pittsburg, Kan., October 8-10.

KENTUCKY INDEPENDENT TELEPHONE ASSOCIATION. Secretary, W. G. Turpine, Henderson, Ky.

MAINE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, M. E. Crow, Houlton, Me.

MAINE STREET RAILWAY ASSOCIATION. Secretary, E. A. Newman, 471 Congress street, Portland, Me.

MASSACHUSETTS STREET RAILWAY ASSOCIATION. Secretary, Charles S. Clark, 70 Kilby street, Boston, Mass. Meets second Wednesday of each month, except July and August.

MASTER CAR BUILDERS' ASSOCIATION. Secretary, J. W. Taylor, 390 Old Colony Building, Chicago, Ill.

MICHIGAN ELECTRIC ASSOCIATION. Secretary, A. C. Marshal, Port Huron, Mich.

MICHIGAN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, A. A. Burch, Battle Creek, Mich.

MISSOURI ELECTRIC LIGHT, GAS AND STREET RAILWAY ASSOCIATION. Secretary, Claude L. Clary, Sikeston Electric Light and Power Company, Sikeston, Mo.

MISSOURI INDEPENDENT TELEPHONE ASSOCIATION. Secretary, George W. Schweer, Windsor, Mo.

NATIONAL ARM, PIN AND BRACKET ASSOCIATION. Secretary, J. B. Magers, Madison, Ind.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION OF THE UNITED STATES. Secretary, W. H. Morton, 94 Genesee street, Utica, N. Y.

NATIONAL ELECTRICAL TRADES ASSOCIATION. Secretary, Frederic P. Vose, 1343 Marquette Building, Chicago.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Secretary, John F. Gilchrist, Commonwealth Edison Company, Chicago, Ill.

NEBRASKA ELECTRICAL ASSOCIATION. Secretary, William Bradford, Lincoln.

NEBRASKA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. E. Mattison, Lincoln, Neb.

NEW ENGLAND ELECTRICAL TRADES ASSOCIATION. Secretary, Alton F. Tupper, 60 State street, Boston, Mass.

NEW ENGLAND STREET RAILWAY CLUB. Secretary, John J. Lane, 12 Pearl street, Boston, Mass. Meetings held on fourth Thursday of each month.

NEW YORK ELECTRICAL SOCIETY. Secretary, G. H. Guy, Engineering Societies Building, 29 West Thirty-ninth street, New York city.

NEW YORK STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. Max Eaton, Niagara Falls, N. Y.

NORTHWESTERN ELECTRICAL ASSOCIATION. Secretary, R. N. Kimball, Kenosha, Wis.

OHIO ELECTRIC LIGHT ASSOCIATION. Secretary, D. L. Gaskill, Greenville, Ohio.

OHIO INDEPENDENT TELEPHONE ASSOCIATION. Secretary, O. O. Welsheimer, Columbus, Ohio.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS. Secretary, F. W. Ballard, Cleveland, Ohio.

OHIO STREET RAILWAY ASSOCIATION. Secretary, Charles Currie, Akron, Ohio.

OKLAHOMA ELECTRIC LIGHT, RAILWAY AND GAS ASSOCIATION. Secretary, Galen Crow, Guthrie, Okla.

OLD TIME TELEGRAPHERS' AND HISTORICAL ASSOCIATION. Secretary, John Brant, 195 Broadway, New York city.

ORDER OF THE REJUVENATED SONS OF JOVE. C. B. Roulet, Mercury, Dallas, Tex. Annual meeting, Buffalo, N. Y., October 15-16.

PACIFIC COAST ELECTRIC TRANSMISSION ASSOCIATION. Secretary, Samuel G. Reed, Portland, Ore.

PENNSYLVANIA ELECTRIC ASSOCIATION. Secretary, E. S. Smith, Towanda.

PENNSYLVANIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, H. E. Bradley, 135 South Second street, Philadelphia.

PENNSYLVANIA STATE STREET RAILWAY ASSOCIATION. Secretary, Charles H. Smith, Lebanon, Pa.

PIKE'S PEAK POLYTECHNIC SOCIETY. Secretary, E. A. Sawyer, Colorado Springs, Col. Meetings, second Saturday of each month.

RAILWAY SIGNAL ASSOCIATION. Secretary, C. C. Rosenberg, Bethlehem, Pa. Annual meeting, Washington, D. C., October 13-15.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION. Secretary, Arthur L. Williston, Pratt Institute, Brooklyn, N. Y.

SOUTH DAKOTA INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, E. R. Buck, Hudson, S. D.

SOUTHWESTERN ELECTRICAL AND GAS ASSOCIATION. Secretary, J. A. Myler.

STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK. Secretary, J. H. Pardee, J. G. White & Company, New York, N. Y.

TEXAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

UNDERWRITERS' NATIONAL ELECTRIC ASSOCIATION. Secretary Electrical Committee, C. M. Goddard, 55 Kilby street, Boston, Mass.

VERMONT AND NEW HAMPSHIRE INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, G. W. Buzzell, St. Johnsbury, Vt.

VERMONT ELECTRICAL ASSOCIATION. Secretary, C. C. Wells, Middlebury Electric Light Company, Middlebury, Vt.

VIRGINIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, B. L. Fisher, Rocky Mount, Va.

WESTERN ASSOCIATION OF ELECTRICAL INSPECTORS. Secretary, W. S. Boyd, 382 Ohio street, Chicago, Ill.

WESTERN SOCIETY OF ENGINEERS (Electrical Section). Secretary, J. H. Warder, 1737 Monadnock Block, Chicago, Ill.

WISCONSIN ELECTRIC AND INTERURBAN RAILWAY ASSOCIATION. Secretary, Clement C. Smith, president Columbia Construction Company, Milwaukee, Wis.

WISCONSIN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. C. Crowley, Jr., Superior, Wis.

DATES AHEAD.

Association of Edison Illuminating Companies. Annual meeting, Lenox, Mass., September 15-17.

Colorado Electric Light, Power and Railway Association, Glenwood Springs, Col., September 16-18.

Old Time Telegraphers' and Historical Association, and Reunion of Military Telegraphers, Niagara Falls, N. Y., September 16-18.

Arkansas Association of Public Utilities Operators. First annual convention, Little Rock, Ark., September 17-18.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 5-6.

Empire State Gas and Electric Association. Annual meeting, New York city, October 7.

Kansas Gas, Water, Electric Light and Street Railway Association. Annual meeting, Pittsburg, Kan., October 8-9.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

Railway Signal Association. Next meeting, Chicago, Ill., September 8. Annual meeting, Washington, D. C., October 13-15.

Order of the Rejuvenated Sons of Jove. Annual meeting, Buffalo, N. Y., October 15-16.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October 20-23.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Record of Electrical Patents.

Week of August 25.

897,273. TROLLEY CATCHER. Michael G. Delaney, Detroit, Mich., assignor to William Degenhart, Buffalo, N. Y. An electromagnet in circuit with the trolley pole actuates the detent controlling the ratchet.

897,278. WIRELESS TELEGRAPHY. Reginald A. Fessenden, Washington, D. C. A receiver is placed in the secondary of an inductive coupling.

897,279. MEANS FOR GENERATING HIGH-FREQUENCY ELECTRIC OSCILLATIONS. Reginald A. Fessenden, Washington, D. C. One of the terminals is made of very thin sheet metal.

897,280. AUTOMATIC STOKING-INDICATOR MECHANISM. Robert Forsyth and William W. Hanscom, San Francisco, Cal. A motor-driven worm mechanism with a complementary audible and visual signal system.

897,291. METHOD OF RENDERING ELECTROLYTIC COPPER HOMOGENEOUS. Marcel A. Jullien and Emile L. Dessolle, Levallois-Perret, France. The metal is electrolytically deposited on a rotatory cylinder.

897,300. ELECTRIC CABLE CLAMP. Ernest W. Muller, Brooklyn, N. Y., assignor to Hubert Krantz, Brooklyn, N. Y. The conducting core is clamped between opposing wedge-shaped insulators.

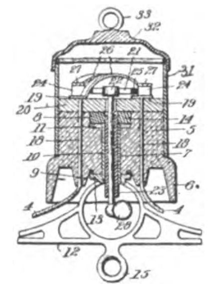
897,304. CONTINUOUS TRACK LIGHT AND AUTOMATIC SIGNAL. John M. Pitney, Jr., Lorain, Ohio. The headlight and a sound signal are operated simultaneously upon the movement of the car.

897,312. ELECTRIC LOCOMOTIVE. Elmer A. Sperry, Brooklyn, N. Y. Each axle is equipped with a motor, and means are provided for rotatively coupling the axles.

897,318. OZONIZER. Jan Steynis, New York, N. Y., and Henri Chaumat, Paris, France. One set of electrodes is stationary and the other movable.

897,326. ELECTRIC HEAT UNIT OR DEVICE. George H. Wade, Atlanta, Ga. Two ribbons of insulating and heat-resisting material are connected by a wire having a high temperature coefficient.

897,350. ELECTRIC STOP MOTION FOR MOTORS AND SIGNAL FOR THE SAME. Adam Cochrane, Lowell, Mass. The circuit is controlled through the medium of a centrifugal governor.



897,457.—Hanger for Electric Lamps.

897,355. ELECTRIC BLOCK-SIGNALING SYSTEM. John W. Davis, Los Angeles, Cal., assignor to Mills-Piddington Cab Signal Company, Los Angeles, Cal. The insulated sections of the rails are provided with magnets effecting the electric connections.

897,394. ELECTROMAGNETIC LOCKING DEVICE. Charles O. Peters, Winthrop, Mass. The core of the electromagnet serves as a detent, and the latch serves as an armature.

897,401. ELECTRIC SIGNALING SYSTEM. Harry C. Reagan, Butler, Pa., assignor of one-half to John H. Barrett, Mars, Pa. A safety stop bar is operated through a single wire for drawing the current-collecting device on the car away from the trolley wire.

897,402. TROLLEY FINDER. Joseph P. Reed, Muncie, Ind. The trolley harp is provided with lateral spring members for taking up rebound.

897,410. CARBON HOLDER. Oscar A. Ross, Chicago, Ill. The electrode is held in a resilient socket member.

897,413. SIGNALING CIRCUIT. Harry O. Rugh, Sandwich, Ill. A pole-changing device acts with a polarized relay to make normal or alternate contacts.

897,454. TELEGRAPHIC TRANSMITTER. George A. Cardwell, New York, N. Y., assignor to Telegraph Transmitting Instrument Company, New York. A keyboard and key levers effect various combinations in the line circuit.

897,455. CLUSTER FIXTURE FOR ELECTRIC LIGHTS. John H. Caldwell, Philadelphia, Pa. A wireless cluster.

897,457. HANGER FOR ELECTRIC LAMPS. George Cutter, South Bend, Ind. A weatherproof insulator and cutout.

897,472. JAR FOR STORAGE BATTERIES. Joseph Marx, Buffalo, N. Y. The inner cell is fitted with an annular rim fitting over the ledge of the outer shell.

897,474. INDICATING FUSE PLUG AND HOLDER. Claude E. Mentzer, Denver, Col., assignor of one-third to Leon A. Freeman and one-third to George L. Bettcher, Denver, Col. An indicating device is released by the burning of the fuse.

897,475. ALTERNATING-CURRENT MOTOR. Maurice Milch, Schenectady, N. Y., assignor to General Electric Company. The primary member is provided with a winding distributed over a portion only of the said member. The secondary member is provided with a short-circuiting winding connected to the segments of a commutator.

897,484. PNEUMATIC CONTROL SYSTEM. Philipp Pforr, Berlin, Germany, assignor to General Electric Company. A contact device for equalizing pressures in the reservoir of an air-brake system.

897,492. ELECTRIC SWITCH. Oran O. Rider, Schenectady, N. Y., assignor to General Electric Company. A double-throw switch having its open position between its two closed positions.

897,497. STARTING AND SPEED-REGULATING RHEOSTAT. Frank J. Seabolt, Schenectady, N. Y., assignor to General Electric Company. A regulating rheostat with a double series of contacts and an electromagnetic device for closing the motor circuit through one of said resistances.

897,501. SYSTEM OF ELECTRICAL DISTRIBUTION. Matthew O. Troy, Schenectady, N. Y., assignor to General Electric Company. A phase-changing rectifier system.

897,507. SYNCHRONOUS MOTOR. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to General Electric Company. The field is provided with phase-splitting means.

897,508. ALTERNATING-CURRENT MOTOR. Ernst F. W. Alexanderson, Schenectady, N. Y., assignor to General Electric Company. The laminated primary member carries two windings of different pole numbers.

897,514. LATCH MECHANISM. Paul Behr, Berlin, Germany, assignor to General Electric Company. An automatic circuit-breaker tripping mechanism.

897,524. BLOCK-SIGNAL SYSTEM. Fred B. Corey, Schenectady, N. Y., assignor to General Electric Company. The signal-controlling relay has one winding connected to the track rails and a plurality of windings supplied with current from a plurality of different circuits.

897,525. ELECTRIC SWITCH. Frank C. De Reamer, Schenectady, N. Y., assignor to General Electric Company. A double-pole fused switch.

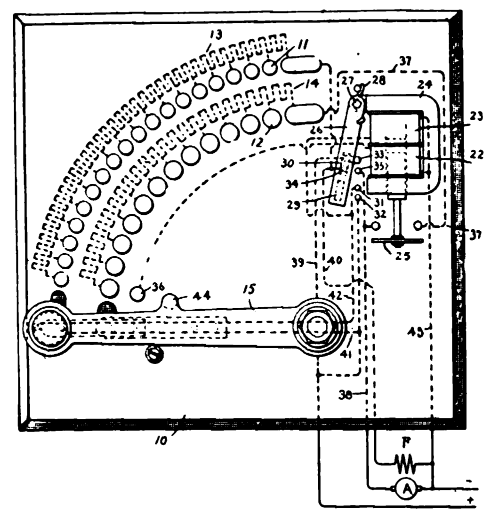
897,531. BLOCK-SIGNAL SYSTEM. Laurence A. Hawkins, Schenectady, N. Y., assignor to General Electric Company. An alternating-current relay control block-signal system.

897,536. MERCURY METER. Frank Holden, London, England, assignor to General Electric Company. The index is moved in the tube by a flow of mercury therein.

897,537. ELECTRIC CONTROLLING SYSTEM. John D. Ihlder, New York, N. Y., assignor to Otis Elevator Company, Jersey City, N. J. The electrodynamic brake circuit automatically controls the resistance in accelerating the motor.

897,538. SYSTEM OF MOTOR CONTROL. Leopold Janisch and Wilhelm Naumann, Berlin, Germany, assignors to General Electric Company. Means are provided for connecting the resistance in parallel with the armature when the controller is moved toward its off position.

897,544. RECTIFIER SYSTEM. Osias O. Kruh, Schenectady, N. Y., assignor to General Electric Company. Mercury rectifiers in series are interpolated in the several phases of the system.



897,497.—Starting and Speed-Regulating Rheostat.

897,545. SINGLE-PHASE COMMUTATOR-MOTOR. Marius C. A. Latour, Paris, France, assignor to General Electric Company. The main field coils are adapted to produce a relative phase displacement of currents.

897,548. ARC-LIGHT ELECTRODE AND METHOD OF MAKING THE SAME. Charles F. Lindsay, Schenectady, N. Y., assignor to General Electric Company. A mixture containing iron oxide and titanium oxide is partly reduced and thereafter subjected in the finished electrode to a reducing action.

897,564. PANEL BOX. Frank S. Wahl, Olean, N. Y. A stamped sectional panel box.

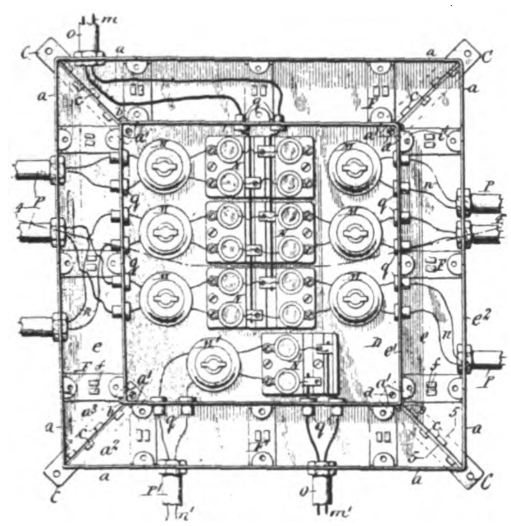
897,569. MEANS FOR PRODUCING ARTIFICIAL LIGHT FOR PHOTOGRAPHERS' USE. Frank E. Barentzen, Malden, Mass., assignor to William G. Burns, Boston, Mass. A closed compartment is separated from the main room by a partition of translucent light-diffusing material.

897,585. ELECTRIC TIME SWITCH. Jules Cauderay, Lausanne, Switzerland. A motor imparts intermittent, partial revolutions to the clock shaft.

897,590. SUBSTATION PROTECTOR. Frank B. Cook, Chicago, Ill. Carbon lightning arresters are connected in series with the fuse members.

897,602. CONTROLLER REGULATOR. Frederick M. Du Bois, Syracuse, N. Y., assignor, by mesne assignments, to American Automotoneer Company, Philadelphia, Pa. An interlocking ratchet movement.

897,603. BUFFING AND GRINDING APPARATUS. Frederick B. Duncan, Madison, Wis., assignor to Northern Electrical Manufacturing Company, Madison, Wis. A self-contained motor-driven buffing and grinding machine.



897,564.—Panel Box.

897,607. AUTOMATIC CALLING-ON SIGNAL. William H. Elliott, New York, N. Y. The signals are capable of being actuated when the section is occupied.

897,614. CLUSTER-LAMP SOCKET. Charles D. Gervin, New York, N. Y., assignor to the Dale Company. A wireless cluster.

897,633. ELECTROLYTIC CELL. Gilbert C. Landis, York, Pa. A tubular metal-carbon cell.

897,657. ELECTRIC AND PNEUMATIC GOVERNOR. William K. Rankin, Philadelphia, Pa., assignor to John E. Reyburn, Philadelphia, Pa. The action of the diaphragm governs the electrical circuit.

897,662. TELEGRAPHIC SELECTIVE SYSTEM. Alfred M. Roberts, Buffalo, N. Y. The selecting magnet responds to the direction of current flow.

897,667. TROLLEY WHEEL. Edward P. Sharp, Buffalo, N. Y. An integrally connecting hub is fitted with rigid outside flanged members.

897,669. INSULATOR. Frank J. Siegwart, Pittsburg, Pa. Means are provided for carrying the connector in an insulating groove.

897,670. ELECTRICAL IMPULSE RECORDER. Augustus K. Sloan, Jr., Brooklyn, N. Y. The moving member of the solenoid is provided with a stylus.

897,674. TERMINAL FOR ELECTRIC FITTINGS. Frederick A. Swan, Cliftondale, Mass. Means are provided for taking the strain off the conductor.

897,681. TELEPHONE SWITCH. Clarence Truitt, Moscow, Ida. Means are provided for signaling another station without calling the telephone exchange.

897,683. CONDUIT CAP FOR ELECTRIC INSTALLATION. Wheeler H. Vibber, New London, Ct., assignor to the Gillette-Vibber Company, New London, Ct. An insulating pipe cap.

897,692. ELECTRIC ORGAN ACTION. William R. Whitehorne, Brooklyn, N. Y., assignor to Whitehorne Organ Action Company, Jersey City, N. J. Each key is provided with a switch, stop mechanism and valve-controlling magnet winding.

897,702. ELECTRIC SIGNAL SYSTEM. Anthony A. Barbera, Philadelphia, Pa. The operation of the semaphore arm actuates an alarm member mounted in the tower house.

897,711. TIME SWITCH FOR ELECTRIC CIRCUITS. Hayden W. Brown, Waterbury, Ct. Means are provided for adjusting the switch mechanism in a predetermined position.

897,713. MOTOR STARTER. Anthony J. Burns, Oswego, N. Y. Means are provided to hold the contact member at open circuit position.

897,716. TRANSMITTER. Jesse T. Curtis, Bement, Ill. The transmitter is equipped with two diaphragms, one diaphragm having adherent to its sunken portion a carbon cup.

897,718. TELEPHONE INSTRUMENT. Wilford R. Daniels, New York, N. Y. An exterior piece for mounting over the ear piece of an ordinary receiver.

897,723. TELEPHONE SYSTEM. William W. Dean, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. The line signal is controlled by a relay.

897,731. SIGNALING DEVICE FOR TELEPHONE EXCHANGES. Thomas W. Gardner, Nashvile, Tenn. Two balanced windings have a common core, and there is a condenser in series with the operator's head-piece receiver.

897,752. OSCILLATING DESK FAN. Evrah C. Lipps, Warren, Ohio, assignor to the Peerless Electric Company, Warren, Ohio. The fan body is oscillated by means of a deflecting vane.

897,758. PROCESS FOR MANUFACTURING INDURATED FIBRE. Israel W. Marshall, Yorklyn, Del., assignor of one-half to Thomas E. Marshall, Yorklyn, Del. A plurality of vegetable paper sheets are subjected to a chemical process whereby they are partially gelatinized.

897,765. MULTIPLE TELEGRAPHONE SYSTEM. George Morin, Habana, Cuba. A plurality of revoluble members are adapted to hold magnetic impressions analogous to sound waves.

897,766. ELECTRIC CIGAR LIGHTER. Ernest P. Muller, Brooklyn, N. Y. Spring contact points are arranged to make contact with an igniting member.

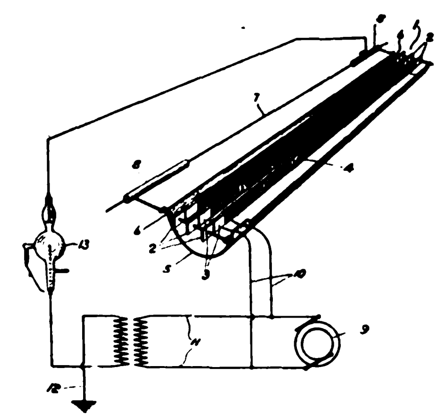
897,779. RECEIVER FOR WIRELESS SIGNALING. Valdemar Poulsen, Copenhagen, Denmark. The signal is impelled by periodically unbalancing or destroying the condition of resonance in the oscillation circuit.

897,800. LIGHTNING ARRESTER. Charles P. Steinmetz, Schenectady, N. Y., assignor to General Electric Company. A combination of spark-gap terminals and a resistance formed of an oxide, the resistance of which decreases when heated.

897,805. INCANDESCENT LAMP SOCKET. William F. Wegner, New York, N. Y., assignor to Stephen T. Williams, New York, N. Y. The socket is adapted to retain the lamp by a direct thrust.

897,812. INVERSE TIME-LIMIT RELAY. Peter Bendmann, Berlin, Germany, assignor to General Electric Company. The armature is operated in a strong magnetic field.

897,823. MARINE SIGNALING LAMP AND THE LIKE. Henry Endall, Southampton, England. A water-tight casing contains an illuminating means.



897,831.—Means for Preventing Offset in Connection with Printing.

897,824. POLE SHOE. William R. Everett and Edwin J. Newton, Chicago, Ill. The pole shoes are equipped with extended arms, these arms being offset on opposite sides.

897,831. MEANS FOR PREVENTING OFFSET IN CONNECTION WITH PRINTING. John Hergesheimer, Philadelphia, Pa., assignor to the Curtis Publishing Company, Philadelphia, Pa. Means are provided for effecting a discharge of the static electricity in the moving sheets.

897,852. SAFETY FUSE. Joseph Sachs, Hartford, Ct., assignor to the Sachs Company, Hartford, Ct. The fuse is comprised of a plurality of separately insulated and sheathed conductors connected in multiple to common electrodes.

897,858. AUTOMATIC CIRCUIT-BREAKER. Henry P. Ball, New York, N. Y., assignor to General Incandescent Arc Light Company, of New York. A double- throw switch which is spring-actuated to its open position.

CONTENTS

THE PENNSYLVANIA ELECTRIC ASSOCIATION.

At the Chicago convention, last May, of the National Electric Light Association, various amendments to the constitution and by-laws were adopted. One important amendment was to the effect that upon application of five Class A members, or two-thirds of all the Class A members, if less than eight, in any state, territory or dependency of the United States or provinces of Canada, the executive committee should authorize the applicants to organize a geographic section of the National Electric Light Association, to which all members of the association in such geographic section should be eligible for membership. When this amendment was adopted it was hardly expected that it would have a working out in a very short time. It is, therefore, at once a matter of congratulation and anxiety that the members of the Pennsylvania Electric Association, which held its first annual convention at Eagles Mere, Pa., last week, unanimously voted to reorganize as a state branch of the National Electric Light Association.

If we mistake not, the idea in the minds of the original members of the Pennsylvania Electric Association was that the national body should be supplemented by a distinct state organization, which organization would necessarily be in entire sympathy with the requirements of the corporations doing business in the state of Pennsylvania, and would be effective to a greater degree statewise than the national organization could possibly be. The presence of the very capable president and several members of the national organization, and the assistance which they were undoubtedly able to render in formulating plans for the development of the state organization, unquestionably made it easy to decide to become part of the greater association, rather than go it alone. The tremendous impetus which the National Electric Light Association has proved itself to be is a matter of immediate concern to every public-utility corporation interested in the supplying of electricity for light and power.

The working out of the present situation will be watched with a great deal of interest, as in almost every state in the Union where there is a state organization, a large number of the members are also members of the national organization. The amendment just discussed, if its advantages are properly applied, will work greatly to the benefit of the member companies, in that it will eliminate a great deal of organization and routine work which, if carried on by a central bureau, would tend to considerable economy, would make effective the strength of all for the benefit of each, and at the same time interfere very little, if at all, with the autonomy of the state organization.

WOOD PRESERVATION.

During the last four or five years the United States Department of Agriculture has given a great deal of attention to the matter of wood preservation, and its files contain much documentary evidence of the value of the research and experimentation which have been carried out along these lines, both here and abroad. A recent publication, circular 139, is a very interesting treatise on the subject of wood preservation, by W. F. Sherfesee.

We are familiar with the ordinary forms of decay which affect organic and inorganic matter. The decay of a plant body such as wood is not an inorganic process like the rusting of iron or the crumbling of stone, and is at the same time different from the process of decomposition of organic structures. It is due to the activities of low forms of plant life, called bacteria and fungi. Fungi, although more complicated than bacteria, are almost as low in the scale of creation when compared with familiar flowering plants and shrubs. The bacteria often consist of but a single cell, microscopic in size. Sometimes several such cells are attached to each other, forming a thread or filament. They multiply by the division of the parent cell into other cells, which, in turn, divide again. Fungi consist merely of tiny threads or hyphæ, which are collectively known as the mycelium. In the higher forms of fungi these mycelium form compact masses of tissue, such as are evidenced by the "punk" of rotting logs or the brackets formed on the trunks of growing trees.

The fruiting of these bodies themselves is not the cause of the decay in wood. Spores, which are very primitive substitutes for seed, and which are borne in the countless compartments into which the under surfaces of the fruiting bodies are divided, are produced in infinite number. When seen in bulk they appear as dust, and, like dust, are carried by the wind and strike all portions of the surrounding objects. Fortunately, few species of fungi successfully attack healthy living trees, and only a comparatively small number attack and destroy wood; yet the spores of some find a lodging in dead portions of a tree or in cut timber, and if the wood is moist and in the right condition for the spore to grow, it germinates and sends out a thin film-like white thread, which, by repeated branching, penetrates the entire structure of the wood.

It is well known that wood is composed of minute cells, the chief material of the cell walls being a substance called cellulose. Around these walls there are encrusted many different organic substances, known collectively as lignin. Most wood-destroying fungi destroy only the lignin; others attack the cellulose alone, while a third class destroys all parts of the wood structure. The lignin and cellulose are dissolved by certain substances secreted in the fungi, and thus serve as food for the fungus growth. Finally, the composition of the wood is so greatly changed that its strength is diminished, the texture becomes brittle and disconnected, and the wood is said to be "rotten."

In addition to the wood food, the fungus requires, however, for its growth and development, heat, air and moisture. If any one of these is lacking the fungus can not develop. We can not deprive the growing plant or the cut timber of heat, and only where the wood is sunk under water at great depths can we deprive it of air. Of the four requirements, therefore, these two are beyond control. It is only by depriving the fungi of moisture or of food that the destruction they cause can be prevented.

Seasoning of timber, which means practically that a certain percentage of the moisture contained has been extracted, adds greatly to the structural value of cut timber; but seasoned lumber is hygroscopic, and can reabsorb a considerable amount of moisture content from which it has once been freed. Of course the climate has a great deal to do with the content of moisture contained in standing timber.

The strength of partially seasoned timber, other things being equal, increases as the amount of moisture it contains decreases. Thoroughly seasoned timber of small sizes is sometimes three or four times as strong as the same timber when green.

It is a mistake to suppose that the germs of decay are inherent in a wood, and several processes for the preservation of wood have failed because they have been founded on this false assumption. The wood-destroying agencies start from the outside, and this explains the partial efficacy of certain paints, which merely form a superficial coating over the surface of the timber, but which are poisonous enough to prevent the spores from germinating. An exterior coating, secured by dipping a post into a thin solution or other material that will harden on the timber, for this reason is not a thoroughly effective protection, because, with shrinking or swelling of the wood, cracks form, through which the agents of decay enter.

Of the processes employed for the treatment of timber with antiseptics, those known as the zinc-chloride treatment and the creosote treatment are generally in common use. These antiseptics are applied by what may be called the pressure-cylinder method, the open-tank method and the brush method. In the pressure-cylinder method the timber is placed in a strongly made cylinder and subjected to heating by steam under pressure. The steam is withdrawn, and a high vacuum established in the cylinder; then the preservative compound is forced into the wood in the cylinder under pressure. After remaining under this influence for a certain time, the lumber is withdrawn from the cylinder and stacked in the open air. In the open-tank method the wood is first thoroughly seasoned by either air or kiln drying, and immersed in a hot bath of the preservative contained in an open tank. The hot bath is continued for a certain time, the moisture and air in the timber passing off in the form of bubbles. At the end of the hot bath the timber is immersed as quickly as possible in a cold preservative, which causes the contraction of the air and moisture remaining in the wood, creating a partial vacuum in the wood cells, which can be destroyed only by the entrance of the preservative. In this way atmospheric pressure accomplishes that for which the artificial pressure is used in the other commercial processes. In the brush method the antiseptic is painted on the surface of the timber, the liquid being applied ordinarily with a common paint brush. In this method care must be taken to check all knots and excoriations, as the liquid can penetrate but a short distance into the wood. This process is, of course, not as thorough as either of the other two, but is of great value where the amount of timber to be treated is too small to justify the erection of a small treating plant, or where the land is so rugged that it is impracticable to transport the timber for even short distances.

From such tests as have been made it appears that if proper care is observed in the treatment of timber, all danger from injury from excessive temperatures can be avoided. The amount of moisture remaining in the wood is of greater importance. Creosote retards both the absorption and evaporation of water; hence its presence in thoroughly seasoned wood exposed to humid conditions tends to conserve its strength; whereas, on the other hand, if it is applied to green wood, the strengthening action of water evaporation is retarded. Zinc chloride and the other preservatives which are in water solution have a wholly different effect. Unless the wood structure is already filled with moisture to the point of saturation, more water is injected into it with the preservative, with the result, if the wood is partially seasoned, of decreasing its strength. The original strength of the wood, however, may be regained by seasoning.

The principal point of superiority of creosote as an antiseptic lies, apparently, in its insolubility in water. Once injected into timber it will not wash out. On the other hand, zinc chloride is much cheaper than creosote, and is shipped more easily, and with lower freight charges; but, since zinc chloride is soluble in water, timber treated with it, when exposed to moisture, will lose its preservative through the leaching out of the chloride; hence zinc chloride is used in comparatively dry situations. Creosote, moreover, is one of the few preservatives within commercial reach that offer absolute protection against the marine borers which work havoc among the wharves of the Atlantic, Gulf and Pacific coasts.

The actual saving due to wood preservation has been demonstrated time and time again, and actual figures have been presented before technical societies within recent years, and are available from the files of the United States Department of Agriculture. The question may be raised whether it can positively be proved that the treated poles will last twenty years. The author holds that a sufficient answer to this argument is that the poles need last only 1.6 years longer than untreated poles in order to justify the cost of treatment. But evidence of the value of preservative treatment is not lacking. It is only a few weeks ago that a contracting company, while installing a twenty-four-duct run for the Empire City Subway Company in New York city, owing to realignment necessary from the excavation work for the Hudson River tunnels, unearthed a block of creosoted conduit which had been under ground since 1887. After twenty-one years it was sound and without the least sign of decay. This conduit has been stored, as it was taken up without breakage, and is now on exhibition in the New York office of the company which manufactured it and laid it in the earth almost a quarter of a century ago.

STREET-LIGHTING CONTRACTS AND THE TUNGSTEN LAMP.

Nowhere in the field of electric lighting has the influence of the tungsten lamp been more directly felt than in street illumination. The increased efficiency and excellent life records which are being maintained by the series tungsten lamp in commercial service are attractive enough to the central station to offset the higher cost of each unit and the supplying of a much larger quantity of light for the same price. The essential features of the tungsten lamp ought to be made perfectly clear, however, to municipal officers and bodies influential in the drawing up of contracts, for there is an excellent opportunity for misunderstandings to arise in connection with the comparative efficiencies of carbon, metallized-filament and tungsten lamps if the lighting question is allowed to be settled for a term of years mainly on the basis of lamp economy.

Nothing is to be gained on the part of the central station by trying to minimize or even conceal the reduction in wattage which so distinguishes the tungsten lamp from its predecessors. A frank policy in this respect is worth everything, and no fair-minded city executive should begrudge a central station the benefits of enhanced lamp efficiency, provided the company makes clear that it is willing to share the benefits with the municipality. This it can do without resorting to prohibitive cuts in prices, provided the fact is borne in mind that the town or city is buying light, and assuming that the authorities are reasonable men, satisfied with a reasonable share in improvements which they risked nothing to obtain, and which they would never have enjoyed but for the willingness of the central stations to spend money on trials and experiments.

Local conditions must naturally in each case determine the rates charged for street lighting by tungsten lamps, but in view of the fact that in many instances the substitution of tungstens for carbon-filament incandescents gives the city an increase of from twenty-eight to sixty per cent in the volume of light emitted from each unit, with the added benefit of maintaining the initial candle-power far beyond the period when the gas-mantle lamp would be fit for respectable service and greatly in excess of the capabilities of the carbon lamp, there ought to be little justice apparent in a rate reduction when the new contract is made up on the tungsten lamp basis. Measuring the output of the series tungsten lamp in candle-power-hours one finds that the central station is giving quite enough to the municipal customer if it does not raise the rate per lamp per year, when the total candle-power-hours of other lighting units are figured. It is sometimes hard for the central station to convince the city authorities that the tungsten lamps will give enough better service to require no reduction in lamp rate, but there is a good chance in such cases to exhibit actual lamps which have burned a known number of hours, and let the non-technical city officials see for themselves the lasting characteristics of the old and the new units. Experience has proved, however, that the making of a new contract on the tungsten-lamp basis may result in a higher rate per lamp per year for the municipality, especially if a longer burning is provided under the new conditions. In one case of this kind the price per year for twenty-five-candle-power carbon series lamps was $16.50 per lamp. When the contract expired a new contract was made upon the basis of thirty-two-candle-power tungstens, burning three hours per night longer during six months of the year. The new price per lamp was $19.30 per year, or an increase of seventeen per cent. Such an illustration of reasonableness on the part of the city officials in dealing with a problem of this character augurs well for other companies who approach the making of a new street-lighting contract with tungsten lamps as the working units, in a broad and far-sighted way.

MOTOR DRIVE FOR THE PRINTER.

Probably in no other industry has so much quiet experimentation been carried on in the adapting of motors to driving machinery as has been the case with the publisher and printer. Years ago, when the availability of the electric motor and automatic control for the driving of machinery was demonstrated, the printer was among the first to have the hardihood to install electricity as a source of power. Great were the claims made for the electric motor. The printer, by temperament, is an enthusiastic person, and rarely goes at things in a half-hearted way. Believing implicitly in the claims made by early solicitors he threw out his gas or oil engine and quarreled with his steam supplier, believing he had every one beaten at the start when he made up his mind to install an electric motor. Many and grievous were his disappointments. In most cases he either installed too much or too little power. Where the first condition prevailed, his bills for current were too high, and the service made but a poor showing against his previous costs for steam driving. Where the second condition prevailed, he was at his wits' end more than half the time because of the stalling of the motor and the disrupting of his circuits for a dozen different good electrical and mechanical reasons.

The printer was usually as enthusiastic in expecting the motor to do wonders as the early solicitor was to promise them. When figuring for power he rarely assumed that he would have all of his machines in operation at one time, and this, of course, was taken advantage of in the installation of his motor. As a matter of fact, however, every once in a while he would require all of his apparatus at one time, and machine after machine would be thrown on, until the belts would start to slip, and presently the motor or some part of the circuit would go out of commission. Then, again, in dispensing with his steam service he, in most cases, counted upon saving the engineer's wages. The foreman of a printing plant is usually a man of considerable intelligence and not a little mechanical ability, and upon him, in large measure, devolved the task of running the motor. While things were going smoothly he got along very well. When the motor commenced to cut up capers he, of course, secured all manner of advice from every one who had a smattering of knowledge more or less technical. It is easy to realize that with some of the earlier installations the motors did some truly wonderful things, carrying overloads which the most sanguine designers and manufacturers never expected them to be capable of. The usual method of curing a sparking commutator was the application of a rag well greased with vaseline. Where fuses were used it was only because they would not blow when they should have blown that the circuit remained intact, and that there was not more trouble is one of the things that can be explained only by the immutable perversity of inanimate objects.

The constant improvement in the design and manufacture of internal-combustion motors and the laying of mains through the streets by steam-distributing companies retarded considerably the introduction of the electric drive. These elements at the same time stimulated the electrical engineers and manufacturers to make a closer study of the needs of the printer, and the result has been that nowhere is the electric drive giving so much satisfaction at the present time as in the printing industry.

It must be understood that from very crude methods of simply closing a switch there have been evolved methods of automatic control which fit almost any possible demand which the printer may make. The adapting of automatic control to the perfecting presses used by the daily newspapers has made necessary the exercising of the greatest possible ingenuity and perseverance. An idea of the complexity of the circuits and the necessity for fine control in operating these machines may be gained from the article which is presented on another page of this issue by Mr. S. H. Sharpsteen. The author gives a very lucid idea of the two-motor drive with automatic control which is very successfully meeting the demand for a safe and reliable source of power.

In getting a perfecting press ready for production, the machine must be put through a series of movements which require a motor that will operate from the slowest possible crawling speed up to the high speed necessary for the rapid production of the daily newspaper whose circulation runs into the hundreds of thousands. Plates must be fastened on, paper threaded in, adjustments of every description made, all under control of the man in charge, and at the same time under control of men working at various parts of the press; for it must be understood that this is a machine of great dimensions, and quite a number of operators must be at work at different parts of the press at the same time. The method of push-button control has been elaborated, and yet so simplified that we rarely hear of an accident either to the machine or to the men operating it.

This is only one phase of the many applications of the motor drive and automatic control to printing machinery. There are numerous installations in the loft buildings all over our larger cities which form a fallow field for the electrical engineer and the designer of electric motors and control apparatus. The employing printer, through his trade societies, very quickly learns of the success with which a brother printer meets in the employment of any new device, and now that it has been demonstrated that the electric drive is a source of economy, he is anxious to take advantage of that economy, outside of his natural desire to have his equipment driven by the latest form of power-producing machinery.

THE STATEMENT OF OHM'S LAW.

BY MORTON G. LLOYD.

In 1826 G. S. Ohm announced the relation between electromotive force and current, which has ever since been regarded as one of the fundamental laws of electrical science. The law discovered by Ohm is that in a definite conductor of the first class,[1] under definite conditions, the current is proportional to the electromotive force which produces it, that is, to the total electromotive force in the circuit. It was applied by him to continuous currents, but it is equally true of conductors in which alternating currents are flowing. Since it is true of the instantaneous current it must hold also for values obtained by summation over a complete cycle.

Put into the form of an equation, using the usual symbols, Ohm's law becomes

$$\frac{E}{I} = \text{a constant.}$$

That is to say, if E be varied while all other conditions remain the same, the ratio $\frac{E}{I}$ remains constant. If some other condition, such as the temperature, be changed, I is again proportional to E, but the ratio has now a different value.

If e be the instantaneous impressed electromotive force in an alternating-current circuit, then we must combine with it the self-induced electromotive force, since Ohm's law applies to the total electromotive force. Thus $\dfrac{e - L\dfrac{di}{dt}}{i} =$ constant, where $\frac{di}{dt}$ represents the rate of change of current and L the inductance. If the circuit or conductor be coupled with a secondary circuit, there will be another component of electromotive force to be considered; thus

$$\frac{e - L\dfrac{di_1}{dt_2} - M\dfrac{di_2}{dt}}{i_1} = \text{constant.}$$

When we consider effective or maximum values in an alternating circuit supplied from a source of sinusoidal electromotive force, Ohm's law may still be applied if the inductance of the circuit be definite and constant (*e. g.*, free from iron). The equation then becomes

$$\frac{\sqrt{E^2 - L^2 p^2 I^2}}{I} = \text{constant,}$$

where E is the electromotive force impressed on the circuit or conductor, and LpI represents the self-induced electromotive force.

If there be capacity in the circuit, its potential forms one component of the electromotive force which must be included in the equation. Thus for instantaneous currents, $\dfrac{e - L\dfrac{di}{dt} - \dfrac{q}{C}}{i} =$ constant, where C is the capacity and q the charge; and for the effective values with sinusoidal currents,

$$\frac{\sqrt{E^2 - I^2\left(pL - \dfrac{1}{pC}\right)^2}}{I} = \text{constant.}$$

When put into this form it is evident that Ohm's law holds for alternating currents, and the idea so often expressed that this law does not hold under these conditions is seen to be due to an erroneous point of view. Just as in the case of continuous currents, the value of the constant is changed whenever the conditions are changed, and here a greater variety of conditions may exist. Thus a variation of frequency, if the latter is sufficiently high, may alter the value of the constant, and in this case the variation of L with the frequency would have to be considered also.

The form which Ohm's law takes in the case of alternating currents is not one which is convenient for computation, and it is due to this fact that the formula involving the expression for impedance has taken its place in the discussion of alternating currents. But it should be borne in mind that the law of Ohm is just as true, for the law then takes on a greater significance.

It should be noticed that up to this point the word *Resistance* has not been used, and I want particularly to lay stress upon the fact that Ohm's law can be discussed without mention of it. Resistance is the name which has been given to the ratio $\frac{E}{I}$ in the case of continuous currents, and the practical units of measurement of the three quantities, electromotive force, current and resistance, have been so chosen that the numerical relation $\frac{E}{I} =$ R holds. When a change of temperature or other condition alters the ratio $\frac{E}{I}$ we say that the resistance changes, in order to keep intact the above relation.

Having defined resistance in terms of the conditions in a continuous-current circuit, it then becomes a matter of experience (or extension of definition) as to whether the same relation holds under other conditions, as, for example, with alternating current. As a matter of fact with sinusoidal currents the radio $\dfrac{\sqrt{E^2 - I^2\left(pL - \dfrac{1}{pC}\right)^2}}{I}$ is still called the resistance, and if the value of this ratio changes with the frequency, for example, again we say that the resistance changes, even though all the physical characteristics of the conductor remain unaltered.

Inasmuch as the conception of resistance is a consequence of Ohm's law, it does not seem desirable to use that term in the expression of the law, at least not in the way that it is so often stated, *viz.*: "The current is equal to the electromotive force divided by the resistance." The law is better stated, from the logical standpoint, by saying that the current is proportional to the electromotive force, or that their ratio is a constant.

[1] *i. e.*, metals, etc. Ohm's law does not hold in gaseous conductors.

The Annual Meeting of the American Electrotherapeutic Association.

The eighteenth annual meeting of the American Electrotherapeutic Association will be held in the Engineering Societies Building, 29 West Thirty-ninth street, New York city, on September 22, 23 and 24. The evening of September 23 will be devoted entirely to the exhibit of apparatus and appliances, which will be held in the large room on the fifth floor, adjoining the usual assembly room of the New York Electrical Society. The association has procured the use of the fifth floor for the three days' session, and the members of the New York Electrical Society, the American Institute of Electrical Engineers and engineers in general are invited to be present during the several sessions.

The Education of Street Railway Employés.

A committee has been appointed by President Goodrich, of the American Street and Interurban Railway Association, to study and report upon efforts which are being made by railway companies to train their employés for efficient service. This committee is composed of Professor H. H. Norris, chairman; R. E. Danforth, Newark, N. J., and Professor A. S. Richey. It is likely that the committee will present a preliminary report at the convention of the American Street and Interurban Railway Association, which will be held at Atlantic City, N. J., next month.

The Huddersfield (England) Municipal Street Railways.

The following statistics concerning the working of the Huddersfield street railways are furnished by Consul F. I. Bright:

"Huddersfield, embracing an area of 11,854 acres, has a population of 100,000 and a ratable value of $2,380,448. Probably in no other town in England of the same population is municipal ownership carried on to the same extent. It was the first city in England to own and operate its tramways.

"Steam was superseded by electric power in 1901. The system now has a little over twenty-eight miles of track, over eight miles of which are double track. Each of the seventy cars has a seating capacity for fifty-six passengers. The ordinary number in use is fifty-six, each running on an average 113 miles from 5 A. M. to 12.45 A. M. The passengers carried in 1907 numbered 16,130,334, at an average fare of 2.4 cents; the total miles run was 1,960,329. The 430 regular employés receive a weekly wage of $2,239. Motormen and conductors work nine hours a day; the shed staff, day, nine hours, and shed staff, night, seven and one-half hours.

"The cost of the permanent way has been $984,167, the total outlay for permanent works, cars, twenty-four waiting rooms, and other property being $2,009,383. An open top car weighing ten tons costs $2,579, a covered top car weighing ten tons fourteen hundredweight, $2,823.

"The total working expenses for the year were $202,943, making an average of 8.7 cents per car-mile, after deducting $31,486 for power expenses. The fares charged run from two cents per 1.23 miles up to eight cents per 6.85 miles.

"From 5 A. M. to 8. A. M. and from 4 P. M. to 10 P. M. cars are available to workmen going to and from work at fifty per cent of the ordinary fares.

"The total income for the last year was $412,212, leaving a gross surplus of $209,269, and, after paying certain amounts of interest on capital, redemption of debt, and depreciation account, a net surplus of $31,700 to be applied to the relief of the general rates.

"During the year there were 262 accidents, caused principally from collisions between cars and other vehicles and by passengers alighting from and boarding cars when in motion. There were no fatal accidents, and less than thirty claims for damages were presented. Third-party risks are covered by insurance, and all such claims are adjusted direct by the insurance company, which receives an annual premium of $3,626.

"There is a postal letterbox attached to each car, which is cleared every hour from 8.30 A. M. to 9.30 P. M. and again at 11 P. M. The number of letters carried in 1907 was 720,512.

"There is no thought here at the present time of adopting the motorbus, in use in a few large cities. The working expenses are regarded as too high."

Edison Electric Illuminating Company of Boston Establishes Illuminating Engineering Department.

The Edison Electric Illuminating Company, of Boston, Mass., has opened a department of illuminating engineering at its general office, 39 Boylston street, Boston. The Edison company has always been one of the foremost in inaugurating enterprising departures, and the company for many years has set the standard in its efforts to promote the use of electricity and give to its customers the advantages accruing from such service. The illuminating engineering department is under the direction of Dr. Louis Bell and H. W. Moses.

The number of customers of the Edison company in the twenty-five cities and towns in which it sells electricity has shown a steady increase during the past few years. On June 30, 1906, the company had 18,963 customers; in 1907 the total was 20,375, and in 1908, 21,719, an increase of six per cent over 1907, and of fourteen per cent over 1906.

BOOK REVIEW.

"Electrical Engineer's Pocketbook." Horatio A. Foster. New York. D. Van Nostrand Company. Flexible leather, gilt edges. 1,600 pages. 4¼ by 6⅞ inches. Supplied by the ELECTRICAL REVIEW for $5.

It has always been easy to say a good word for Foster's "Electrical Engineer's Pocketbook." Having praised previous editions so highly, it is difficult to find an expression which will appear commensurate with the greatly improved construction and quality of the present volume, which constitutes the fifth edition. Some idea of the value of the work may be gained if we repeat the enthusiastic comment of an engineer after examining the work carefully and critically. He said: "This is the last word in electrical handbooks."

The work has been divided into a number of sections, and each of the sections has been revised by a specialist eminent in his particular field. The value of such revision can not be gainsaid when the weight of such authority is attached to the revision. The list of contributors includes the following: Symbols, Units, Instruments—W. N. Goodwin, Jr., and J. Frank Stevens; Measurements—W. N. Goodwin, Jr., and Professor Samuel Sheldon; Magnetic Properties of Iron Electromagnets—Townsend Wolcott and Professor Samuel Sheldon; Properties of Conductors and Properties of Conductors Carrying Alternating Currents—Harvey Pender; Dimensions of Conductors for Distribution Systems, Harvey Pender; Dynamos and Motors—Cecil P. Poole and E. B. Raymond; Tests of Dynamos and Motors and Alternating-Current Machines—E. B. Raymond and Cecil P. Poole; The Static Transformer—W. S. Moody and K. C. Randall; Incandescent Electric Lighting—Dr. C. H. Sharp; Arc Electric Lighting—J. H. Hallberg; Illuminating Engineering—Dr. C. H. Sharp; Electric Railways—A. H. Armstrong, C. Renshaw, N. W. Storer and Milton W. Franklin; Electrolysis—A. A. Knudson; Transmission of Power—Dr. F. A. C. Perrine; Storage Batteries—Lamar Lyndon; Switchboards—H. W. Young, B. P. Rowe and E. M. Hewlett; Lightning Arresters—Townsend Wolcott; Electricity Meters—H. W. Young and J. B. Baker; Telegraphy—Charles Thom; Wireless Telegraphy—F. K. Vreeland; Telephony—J. L. Wayne; Electricity in the United States Army—G. H. Powell; Electricity in the United States Navy—J. J. Crain; Resonance—Lamar Lyndon; Electric Automobiles—C. J. Spencer; Electrochemistry and Electrometallurgy—Professor F. B. Crocker and Professor M. Arendt; X-Rays—Edward Lyndon; Electric Heating, Cooking and Welding—Max Loewenthal; Lightning Conductors—Professor Alex G. McAdie; Mechanical Section—W. W. Christie.

The section on resonance, by Lamar Lyndon, affords a particularly lucid presentation of this difficult subject, and the chapter on electric heating, cooking and welding, as well as the chapter on wireless telegraphy, brings down to date some very useful information for which there has been considerable demand within the last few years. The copious index and the thorough system of cross-indexing, together with the marginal thumb references, make the finding of information on any subject almost an instantaneous process.

Public Utilities in Germany.

Consul Thomas H. Norton, of Chemnitz, states that a recent statistical summary of the extent to which public utilities are now under the direct management of German municipalities shows that the movement is constantly gaining in momentum and that the field of activity is steadily being broadened. The consul's review continues:

"There are now fifty-eight cities in the Empire, containing over 50,000 inhabitants. In these cities the leading utilities are owned and conducted by the municipalities to the following extent:

Public Utilities.	Number of Cities.
Gasworks	44
Electric power plant	38
Waterworks	43
Abbatoirs	47
Bath houses	42
Street railroads	10
Removal of garbage and sewage	56
Market halls	16
Tenement houses (chiefly for municipal employés and laborers)	22

"In regard to financial results the gasworks make the best showing. Their total profits amount annually to $10,100,000. Of this sum about $2,500,000 is required for interest on the investment. Electrical works show a profit of $4,200,000, of which $1,300,000 is expended for interest. Waterworks return on an average 8.5 per cent of the capital invested. Market halls and tenements yield but little profit.

"The entire capital invested by German municipalities in plants for public utilities is now estimated at nearly $1,000,000,000. The value of forests and meadows, as well as the capital of municipal banks and loaning organizations, is not included in this total.

"While so much activity in this field is developed by the German cities, there is but little evidence of a tendency to invade indiscriminately the economic territory of general industrial competition. Municipal control is established when there is simply the choice between a public and a private monopoly, as in the case of gas, water, electricity, etc., or else when the desirability of a utility is unquestioned, but the uncertainty as to profitable returns fails to attract private capital. There is but little probability that German municipal enterprise will step outside these limitations.

"The telegraph and telephone in Germany are owned and managed by the Imperial Government, and most of the railway lines are the property of the different states."

Canadian Electrical Power.

In continuation of Consul Shepard's report, Consul A. G. Seyfert writes from Owen Sound that the hydroelectric power transmission plan from Niagara Falls to the towns and cities of western Ontario has at last reached the period when the contract for the erection of the line has been let. Mr. Seyfert continues:

"The total length of line to be built is 293 miles, with 3,176 steel towers. The contract calls for a main line from Niagara Falls to Dundas, with lines from the latter place to Toronto, London, St. Mary's and St. Thomas, and was let to a construction company for $1,270,000, the lowest of twenty-seven tenders, and includes all the lines in one contract.

"The head of the construction company is an American, who was formerly connected with some of the Canadian railways. The line as now planned covers only western Ontario, but there is an important concession clause in it for additional lines of equal length to cover eastern Ontario at any such time as the people of that section of the province may ask for the privilege of Niagara power.

"The contract will necessitate the use of 507 tons of aluminum wire, together with 140,000 pounds of telephone wire. The towers will be sixty-six feet high and consume 6,554 tons of steel to build them. The estimated cost of the towers is $621,000. The work is to be completed by December 1, 1909. The material for the construction of this gigantic electric power transmission scheme is to be Canadian-made as far as it is possible to secure it."

Rapid-Telegraphy Invention.

A report from Consul Joseph I. Brittain, at Prague, states that the European papers have been devoting considerable space to the invention of a Hungarian by which it is said the inventor may transmit 40,000 words per hour over a telephone line. The consul furnishes the following description:

"The machine consists of three parts: a perforator, transmitter, and receiver. The first may be worked by a typewriter, while the other two are automatic, working through the agencies of electricity and photography, and the instrument may be connected by an ordinary telephone line.

"Through operating the keys of the perforator the operator writes messages upon a long paper ribbon. By touching the keys a series of holes is punched in the ribbon, each set of holes representing a letter.

"After taking the ribbon from the perforator, the inventor places it in a small cylinder in the transmitter, and a touch of the switch sets the cylinder revolving and the ribbon with it. Before the ribbon has completely passed through the transmitter, a second broader strip of sensitized paper issues from the receiver, and upon it is written, in plain, legible characters, the actual message which the inventor or operator has written on the typewriter."

Wireless Telegraphy in Pacific.

Consul Julius D. Dreher sends from Tahiti the following information in regard to a network of wireless telegraphy which it is proposed to establish among the scattered islands of the Pacific Ocean:

"Capitalists who are interested in the extensive phosphate operations on Ocean and Pleasant islands of the Gilbert group, and in the new works about to be established on the island of Makatea of the Tuamotu Archipelago, have recently begun a movement to connect nearly all the groups of islands in the South Pacific by a system of wireless telegraphy.

"It is expected that the various governments having possessions in the South Pacific will aid in the establishment of the proposed system. Negotiations have already proceeded so far that the success of the efforts seems to be almost assured. As the nearest available ocean cable office to Tahiti is at Auckland, 2,250 miles away, from which a steamship of the Union Line of New Zealand arrives at Papeete once every twenty-eight days, and a direct communication by steamship of the Oceanic Company with San Francisco, 3,658 miles distant, is had once in every thirty-six days, it will be understood how deeply interested the French colony of Tahiti and its dependencies are in the complete success of these negotiations. Other groups of islands are equally interested in the establishment of this system, which means so much to the inhabitants of these widely separated archipelagoes.

"The name of the proposed company is the Pacific Islands Radio-Telegraph Company. Of the proposed capital of £70,000 ($340,000), the owners of the phosphate deposits on Ocean and Pleasant islands have subscribed £10,000. In this radial system there will probably be ten or twelve circles, the largest having a radius of 1,250 miles, and requiring for each station an engine of sixty horsepower. It has not yet been decided where the main office of the proposed company will be."

[Names of those interested in the enterprise may be obtained from the Bureau of Manufactures, Washington, D. C.]

TWO-MOTOR DRIVE—AUTOMATIC WEB-PRINTING-PRESS CONTROL.

BY S. H. SHARPSTEEN.

When the electric motor commenced to assume commercial shape the printing-press fraternity wanted electric drive. Standard motor parts, the result of years of the best electrical engineering development, were discarded and a poor special motor was demanded. Hand motor control for printing-press purposes was making good progress, when, to a great extent, the printer became interested in and purchased automatic control. Common business sense was the cause of discarding the special motor for one of standard manufacture, and possibly for the same reason much of the automatic electrical apparatus that is now found in the newspaper print shop will be discarded and more simple and durable devices used.

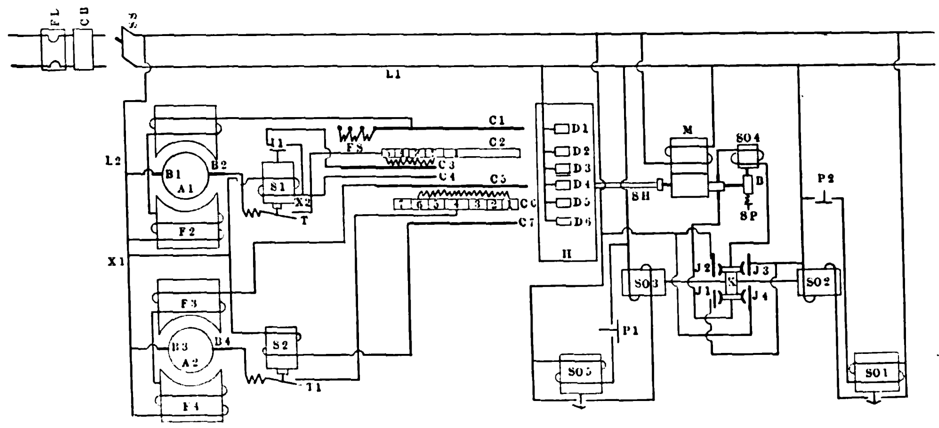
A newspaper web press is, as a rule, a large machine with very many parts. Adjusting, oiling, cleaning, repairing, plating, inking and threading in paper require men to work at its different parts at the same time. Because of the valuable space occupied in the business districts of large cities by these presses, the designing engineers are constantly decreasing the outside dimensions compared to the output of papers; the result is that pressmen have to do their work in close proximity to press parts that sometimes are still, other times moving slowly and often when the whole mass of moving gears and pinions is making a thundering noise and many tons of iron and steel shafts, drums and cylinders are revolving rapidly.

These conditions cause a demand for a means of stopping newspaper presses quickly from convenient places. Large sums of money have been expended for newspaper web-press control, but no device has been put into practical use for properly braking these machines. There are brakes that, when applied, retard the motion of the press, but they are used only in emergency on high-speed newspaper presses and are operated by a circuit of two small wires run around a press with push-buttons convenient for the men to use. This part of automatic or remote control is universally considered as good and proper.

The newspaper web-press builders and users are also of the opinion that automatic control from a number of convenient stations is proper for getting threading and plating speeds, a brake being used to stop the press as soon as a stop-button is pushed. Present methods of braking a web press automatically to stop it quickly are allowable when moving slowly for threading and similar work.

The newspaper man who is responsible for the lives of pressmen and the finances of a large paper—one who realizes the many tons of iron and steel that revolve at a terrific speed high up in the press-room and knows of instances when parts have come loose where certain presses were producing, these parts passing down between drums and cylinders—is inclined to place the production drive of his presses under the absolute control of a cool-headed person who has more than the ordinary mechanical ability.

When all-automatic control was first installed there was no objection to many buttons at each control station, but later, to dispense with costly complication of wiring and the trouble arising from pushing the wrong button when there were too many to select from, the number of buttons was reduced.



TWO-MOTOR DRIVE—AUTOMATIC WEB-PRINTING-PRESS CONTROL.

Certain recent installations have so few buttons at each station that large solenoid windings are closed when the main press switch is put in, thus reducing the cost of installation and the number of buttons at each station, but causing excessive use of current.

In newspaper electric drive and control each station usually contains at least four buttons or switches: one for speed ahead, one for slowing down or stop, one for emergency stop and brake and one for what is commonly called locking the press.

The diagram herewith illustrates two-motor drive with automatic control, A_1 being the armature of the larger motor, its circuit being opened and closed by a contactor, S_1. A_2 is the armature of the smaller motor, its circuit being opened and closed by a contactor S_2.

The movable part of the controller H is moved back and forth on guides by a motor, M, instead of swinging on a stud like the hand controller.

The motor M is shunt wound to produce as nearly as possible a constant speed as soon as its armature circuit is closed when running either way, its field being constantly excited when the main switch SS is in. The motor rotation is changed by reversing its armature current at the switch K, the solenoids SO_2 and SO_3 operating this switch. Assume that push-button P_2 causes the motor M to move the brush carrier H in the forward direction to start the large motor ahead. This button or switch can close a circuit to pass current around solenoid SO_2 or, since it might take more current to operate SO_2 than it would be advisable to carry about the press, the button P_1 could close the coil circuit of a solenoid switch, SO_1, this switch in turn closing the coil circuit of SO_2. When ready to start, pushing button P_2 would cause SO_1 and SO_2 to act as mentioned to force K against J_3 and J_4, passing current to release the solenoid brake SO_4 and turn the armature of M, which by means of the screw SH passes the controller brush carrier H to the left, first exciting the fields of the motors as brush D_1 touches C_1 and brush D_4 touches C_5. D_5 passing on to C_6 closes the armature circuit A_2 in the controller just before D_6 touches C_7, passing current through the coil of contactor S_2 and causing it to complete a circuit through the auxiliary armature A_2 and turn the press and large motor slowly. If a threading speed should be desired the button P_2 would be held down until D_5 reached point 4 on dial C_6, when the starting resistance would be out of circuit with armature A_2 and then released, opening the coil of SO_1, which would, in turn, open the coil of SO_2, releasing and allowing a spring to move switch K to neutral position, thus not allowing current to pass through the armature of motor M and brake solenoid SO_4, dispensing with the power that moved the carrier H and applying a brake to the shaft SH at B, causing it to come to rest immediately.

After threading in paper, and production speed is required, P_2 is again held down, causing the motor M to move the carrier slowly to the left and when D_2 passes on to point 2 of dial C_2 the large motor armature circuit will be completed in the controller ready for the solenoid switch S_1 to pass current through the armature of the main drive when D_3 touches C_3 and C_4 making the final closing in the circuit of armature A_1 at T. For a short time both motors will be furnishing power to drive the press, but there being the proper amount of resistance in circuit with the large armature it will not increase the speed of the press too much at this point, and since the small armature is running in full field it soon ceases to increase in speed as the large motor takes the load. As the carrier H continues to move, resistance is cut out of circuit with the large armature, A_1, and in circuit with the small one, A_2, until D_6 leaves dial C_7, making contactor S_2 open, when the small motor comes to rest. The armature A is connected to the equipment by a ratchet device that permits it to drive but not to be driven. When the desired speed is reached P_2 is permitted to open, allowing carrier H to stand until some change in the press movement is demanded.

If it be desired to diminish the speed of the press, holding down push-button P_1 will cause automatic switch SO_5 to close a circuit and pass current through the coil of solenoid SO_3 forcing the switch K against J_1 and J_2, releasing the brake SO_4, and turning the armature in motor M in the reverse direction, pulling the brush carrier to the right.

When D_4 reaches C_5 the field of the small motor will be excited; later D_5 will touch point 7, dial C_6, and close its armature in the controller, and current will be passed to start this auxiliary machine when D_6 passes on to C_7 causing the contactor S_2 to close at T_1.

When D_5 reaches point 4, dial C_6, the small motor takes the load and all current is cut off from the large motor except, possibly, its fields.

Controller brush D_3 might be adjustable to allow moving to the right or left in the carrier H, permitting the contactor coil circuit S_1 to be excited to pass current at the proper time to close the circuit of armature A_1. For the same reason it would be convenient to have D_6 adjustable.

Point 4, dial C_6, should be long enough to allow the press to be brought to threading speed easily without starting the large motor.

Without a brake to stop the shaft SH when the buttons P_1 or P_2 are released, the momentum of the armature of motor M would possibly carry H beyond the desired point. Motor M being of small capacity the armature could be constructed to start on line voltage. The spring SP applies the brake, the solenoid SO_4 releasing it.

The coil circuit that operates contactor S_1 is connected with one side of the line L_2 at X_1, passes through S_1 and when brush D_3 rests on C_4 is also connected with the other line L_1 through C_4 and D_3. After D_3 touches C_4 and lifts the plunger in S_1, the coil in S_1 has a second branch circuit to D_3 commencing at X_2, passing through I_1 reaching D_3 through the strip C_3. As the brush holder H moves on to the left, D_3 leaves C_4 and opens the coil winding of S_1 that made it pick up the contactor lever and close the armature circuit of the large motor at T, but the exciting circuit of S_1 is kept closed by its auxiliary circuit. If the line current should be interrupted while the press is running for production the movable core in S_1 falls, opening the auxiliary circuit at I_1, the main circuit of S_1 passing through C_4, also being open in the controller; when the current comes on the line the motor armature circuit is open at T and can not be closed until H is returned to let D_3 touch C_4, when the small motor would have the press started and armature resistance would again be in circuit to prevent the large motor from producing too much torque.

Contactors are special devices for opening and closing motor circuits. They are made to rub hard to keep clean at point of contact and a magnetic flux forces out what might cause a burning arc. The controller brush carrier moves the brush slowly, giving an arc time to form and burn. The contactor opens and closes circuits quickly. As the contactor S_2 closes the small motor armature circuit during the reverse motion of H it can not have the usual auxiliary circuit, but since it only moves the press slowly and is of so small capacity, it could do a press no harm by producing extra torque if it were provided with the proper overload release device. The advisability of using a contactor to protect the small motor parts from burning is a question. It should at least have a circuit breaker, which would be the cheaper, saving complication in the brush carrier H.

If a contactor is used it should be supplemented with a fuse and an automatic overload device in the armature circuit of the small motor alone.

As the field-exciting current of the large motor has ample time to come up to full strength while the small motor is starting the equipment, it would seem that good practice would have it opened when the equipment was at rest, even though the service switch be closed. It will make the control a little more expensive but will save current and keep up the efficiency.

The field discharge of a large motor is severe on the insulation, but equipments can be constructed to stand it even though a special discharge path be necessary. Presses are sometimes at rest for hours with the service switch closed, and the current passing through the field coils of the motors is not only wasted but tends to keep up the temperature of the motors and the surrounding space. This heat is bad for the presses in hot weather.

As the auxiliary motor does not have to be reversed, and is of a size that is quickly excited, economy demands that its fields be opened while the press is at rest and the switch closed and also while running for production, thus increasing the efficiency and keeping down the heat.

The contact brushes in the controlling devices and the points in the dials of printing-press control, even though they be the best, sooner or later require adjustment or repairs. The designing engineers of such apparatus have planned these parts so that they are difficult to remove and inspect. If an arm is used, as in manual control, the lift of the springs holding down the brushes causes a strain on the stud around which the arm moves. With automatic control if the brush is worked by gravity or solenoid and the contact pieces get slightly roughened, as often occurs, the brush refuses to move until overhauled. The controller brush carrier illustrated can be constructed to be held in line to prevent the brushes from rocking as the carrier moves. It will be easy to lift out for the inspection of the faces of the brushes, cleaning of the brush holders and to be replaced by an extra carrier if so desired.

The motor M should be designed to allow a large range of speed variation by field change. This arrangement will permit H to be driven to suit the press.

Provision should be made to have the

brush carrier H open the circuit of SO_2 at the extreme travel in one direction and SO_3 at the extreme travel in the other direction to prevent the motor M doing damage if a push-button refuses to operate or is held down too long by an employé. A flexible coupling between the shaft of motor M and screw SH designed to automatically disconnect these revolving parts in case of emergency is also good practice.

Controller brushes conducting the current from the movable controller parts to the dials or metal strips and blocks on controller faces or in automatic controlling devices do not always get the proper consideration. The right carbon or composition controller brush will not cut hard-drawn copper when moving with controller speed and proper brush tension. The brush, instead, gives the copper a smooth finish. It seems reasonable to say that only the best hard copper should be used for this purpose with provision for sufficient brush surface to guard against burn or arc oxidation even though several times the maximum running current might pass. A very large brush capacity compared to the current to be carried might be provided and still have the parts roughened and burned. The brush should be in two pieces at least, each piece provided with a spring, each spring having its own adjustment.

If the brushes are carried or moved by a holder, in which they are supported to feed down as they wear, this holder should be made of hard metal nicely trued and polished inside. The brushes should be accurately fitted to prevent jamming or binding and not loose enough to allow dirt to get between them and the holder. The deeper the holder the less liable the brush will be to tip and touch in a small spot only as it is reversed in motion. If the holder tipped back and forth at the ends of travel the brushes would tend to wear like rockers and present but a small surface to the dial. Pigtail brushes or a brush with a copper cable to be screwed fast to the brush rigging would be good, especially for armature circuits.

Armature resistance dial blocks, when packed solid with mica like a commutator, should have as good construction as a commutator, as they usually get hot from the heat conducted from the grids and if this change in temperature loosens the parts sparking and burning may follow.

If a newspaper web-press controller is what the electrical manufacturer can furnish, and the print shop should have, it will require no grease or vaseline between controller brushes and dials. Old-time controlling devices with copper traveling on copper usually require something to prevent cutting. When weight and space are very important, as in street railway work, this might do, but not in a first-class web-press equipment.

Since there are, in most cases with web-press electric drive, coils always in circuit when the main switch is closed, a switch should be provided with a means of operation that will induce the pressmen to keep it open when the press is at rest. If a good automatic switch, large enough to carry current for the equipment is installed, and its make and break controlled by a series circuit running around the press, and this circuit provided with a push-button switch at each control station, it would be an easy matter for the employé to open the line when the press is standing. Opening the coil circuit of this main switch by means of the small push-button switches at the different stations would answer for a lock, the station switches being in series, and an employé would be assured that the press could not be started if the lock was on at the station near where he was working.

If it were found advisable to place a small circuit-controlling device on the controlling panel to close and open the coil of the main solenoid switch, this smaller automatic switch could have its winding connected into a series circuit for press stations instead of that of the larger switch. The automatic switch and its auxiliary if placed in a cabinet with a glass front and locked up could not be operated by hand when the usual lock was on and some person working in the press. This main automatic switch could be designed to close a brake circuit when the line current was cut off the press equipment. The brake could be applied for emergency by the same buttons that were used for lock. If it were deemed advisable to have a separate button for an emergency brake to save confusion, the customary red push could be placed in the series-lock circuit that would answer for a quick shut-down. A first-class, double-pole circuit-breaker CB is the most reliable device to prevent a destructive inrush of current in case of a metallic cross.

A breaker having a push-button release could be installed and arranged to close a dynamic or other break circuit instead of using the automatic switch for breaking purposes. An equipment with automatic main switch used for lock purposes and a circuit-breaker with a red button circuit both as above described would have three ways of bringing the equipment to rest: First, by the slow-down button which would take time to allow the brush carrier to come to off position; second, the lock button that would cut off the main current and allow the press to slow down without brake—this should be quicker than the first method of stopping; third, the red button to trip the circuit-breaker and apply the brake.

Some designers of motor-control apparatus might advise putting overload relays in circuit with contactor S_1 and armature A_1, also contactor S_2 and armature A_2, in place of using a circuit-breaker. The contactors could be furnished with brake-operating devices and the contactor coils controlled by push-buttons, thus providing emergency stop.

If both sides of the circuit were conducted into the brush carrier H, two sets of brushes and contact pieces would be necessary for this purpose. A cable or cables made up of very fine strands would answer but would not be as neat in appearance as the brushes and contact strips.

The motor that is used to drive a web press for production should be constructed to have speed control by field change sufficient to allow line voltage at the armature brushes at all producing speeds.

The resistance FS at the left end of dial C_1 will be inserted in the field circuit of the large motor after brush D_1 passes from the long strip in dial C_1 causing the motor to increase in speed.

Central Electric Railway Association.

The first bimonthly meeting for the fall of 1908 of the Central Electric Railway Association, of Indiana and Ohio, will be held at Indianapolis, Ind., September 24. Headquarters will be established at the Claypool Hotel. The following papers are announced: "Recent Developments of Lightning Arresters," by David B. Rushmore, engineer, power and mining department, General Electric Company, Schenectady, N. Y.; "The Benefits of the Index Bureau," by Ellis C. Carpenter, general claim adjuster, Indiana Union Traction Company, Anderson, Ind.; "Electric Railway Return Circuit," by E. G. Hindert, chief engineer of power, Cleveland, Southwestern & Columbus Railway, Elyria, Ohio. A paper will also be read by G. H. Kelsay, superintendent of power, Indiana Union Traction Company, Anderson, Ind.

Entertainment will be furnished by the Glee Club of the Indiana Union Traction Company.

THE TEST-METER METHOD OF TESTING SERVICE METERS—V.

(Concluded.)

BY JOSEPH B. BAKER.

A COMMERCIAL TEST METER OF THE "PORTABLE STANDARD" TYPE: THE WESTINGHOUSE PORTABLE STANDARD INTEGRATING WATTMETER.

In general appearance the Westinghouse portable standard integrating wattmeter (Figs. 16 and 17) is not unlike the other forms of commercial test meter that have been described. In the preceding articles it is contained in a polished-wood carrying case with strap and removable cover; it has a large dial, readable from a distance, and a plug switch for changing its capacity to adapt it to the testing of various capacities of service meters; it is started and stopped electrically, so that the use of a stop watch is eliminated; and the testing procedure with it is substantially the same. In fact, except for certain details of construction, to be described, the general description of commercial test meters of the Mowbray type, above, applies (roughly speaking) to this make of test meter.

The theory of its design, however, is entirely different in that this test meter is essentially a *portable standard* meter of adjustable capacity, *i. e.*, an instrument that may be transformed into a test meter of full-load capacity equal to that of the service meter under test, and is not a test meter having a "composite field" winding for giving it a high torque on light load as well as full load of the meter under test.

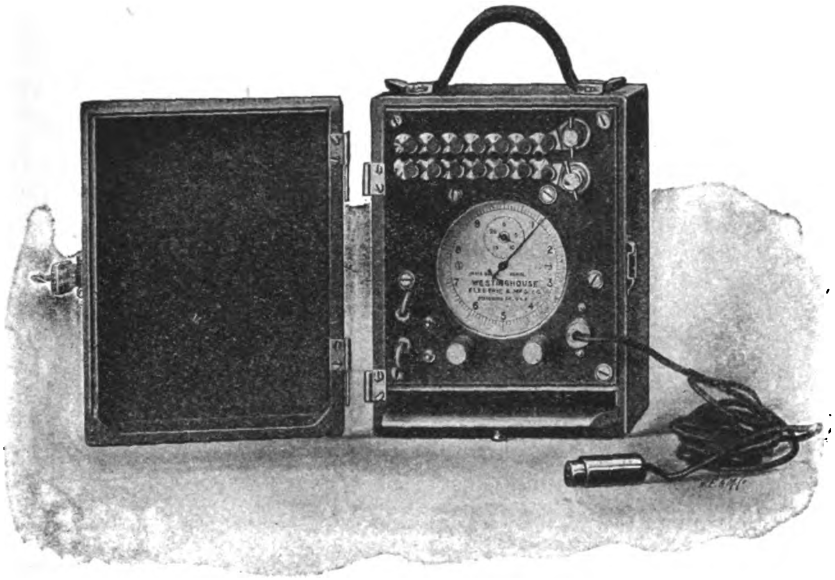


FIG. 16.—WESTINGHOUSE PORTABLE STANDARD INTEGRATING WATTMETER.

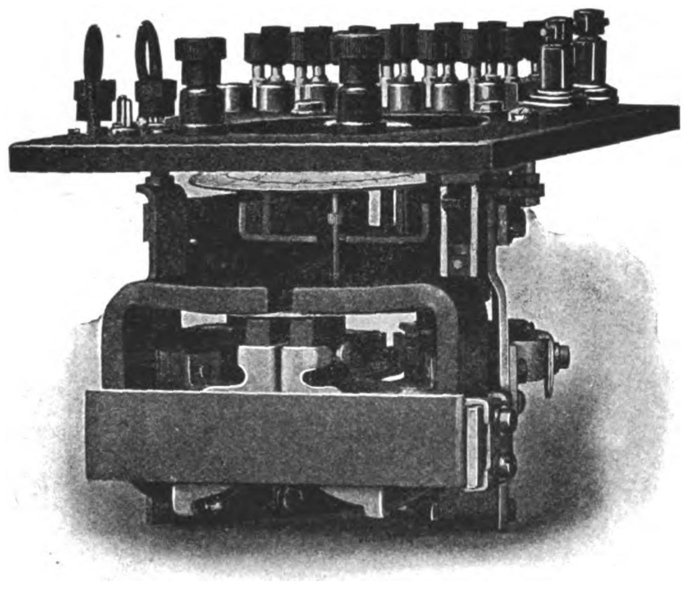

FIG. 17.—INTERIOR VIEW OF WESTINGHOUSE PORTABLE STANDARD INTEGRATING WATTMETER.

In this respect the Westinghouse test meter returns to the original practice of using a portable standard for testing service meters, with the important difference that a single instrument suffices to test service meters of widely varying capacities. Installed meters may run in something like the following distribution in a given central station system: fifty per cent in meters of five-ampere capacity and under; twenty-five per cent in ten-ampere meters, and twenty-five per cent scattering among twenty-ampere, forty-ampere and eighty-ampere capacities.

It is of advantage to have the rotating standard synchronous with the meter under test to save time and risk of personal error. With a test meter having high accuracy on light load (such as is claimed for the Westinghouse induction meters by reason of the ball jewel and light rotating element) this advantage can be attained. Another advantage is that for testing a given service meter the test meter may be connected up to constitute a meter of same capacity as the service meter, which insures comparing the service meter and test meter (which, it may be remarked in passing, should be of the same make), at the same points on their characteristic curve.

The simplicity in testing attained by the use of a test meter synchronous with the service meter under test may be illustrated by the following example: If the service meter (of Westinghouse type, making twenty-five revolutions per minute at full load) makes ten revolutions in a given time, while the test meter makes 10.5 revolutions, the ratio would be 95 +, showing that the service meter is 5 — per cent slow. When the service meter has a different full-load speed than the test meter, an appropriate multiplier must be used. Every Westinghouse portable standard integrating wattmeter is provided with a table to facilitate the testing of service meters in which the full-load speed is other than the standard speed of twenty-five revolutions per minute for Westinghouse meters.

Conditions may arise such that a meter, though accurately calibrated, will be in error several per cent. Then assume that in a certain meter the load error at forty per cent of full load is + 1.0 per cent; that an increase of frequency of ten per cent above normal (from sixty to sixty-six cycles) results in an error of + 1.0 per cent, and that ten per cent lowering of voltage from normal results in an error of + 1.0 per cent. The result is from these coincidal service conditions a total error of + 3.0 per cent in the meter.

The Westinghouse portable standard integrating wattmeter (see Figs. 16 and 17), manufactured by the Westinghouse Electric and Manufacturing Company, is designed for testing 100 and 200-volt alternating-current meters of a wide range of capacity by operating at normal load on five, ten, twenty and forty amperes (full-load speed with 500, 1,000, 2,000, 4,000 and 8,000 watts) by the use of a composite current coil or series field. This wide range means that the portable standard can test, with equal accuracy, a three-ampere, 100-volt or 200-volt meter on light load, and a sixty-ampere, 100-volt or 200-volt meter on full load. It is made available for testing service meters of other capacities by the use of a Westinghouse portable meter transformer, with the secondary connected to the five-ampere current winding. The main pointer revolves twenty-five times per minute under full load and the full-load torque is eight to nine centimetre-grammes. The meter proper, minus the register, is identical with the standard Type B Westinghouse alternating-current service meter, and the calibrating adjustments are therefore the same as in that meter.

A general view of this test meter, standing on one end with its casing removed, is given in Fig. 17. The test meter is operated, however, in a horizontal position (test-meter shaft vertical) like other makes. It is contained in a seven-and-one-half by eight by nine-and-one-half-inch carrying case. The register differs markedly from those of other makes of test meter, as it contains only two dials, having a ratio of 25 to 1 instead of 10 to 1. The main dial, of a good size relatively to the size of the test-meter top, is divided into hundredths and swept by a pointer fixed on the end of the shaft, as usual; but the smaller dial, placed within the main dial, has a pointer which makes one complete revolution for every twenty-five revolutions of the main pointer. The shunt field is subdivided into two windings, which may be connected in series when the test meter is in use on 200-volt circuits, and in parallel for 100-volt circuits, by changing the position of receptacles attached to short cords —in the lower left-hand corner of the top plate, in the position of the test meter in Fig. 16. Instead of a "pendent" snap switch, for starting and stopping the test meter by closing and opening the potential circuit, a push button is employed.

The employment of a push button instead of a switch has the apparent advantages that it is easier with the former to "coax" the main pointer of the test meter into any desired position for beginning a test, and simpler to start and stop the test, by pressing and releasing the button with the thumb.

The push button is connected at the end of a long flexible cord, having a plug at the other end for insertion in a receptacle in the top plate of the test meter (in the lower right-hand corner in the view) to which the potential circuit of the latter is wired. A compartment is provided in the end of the case for stowing away the cord and push button when the test meter is not in use.

Below the register dials and at the left of the push-button plug is a pair of binding posts for the potential connection to the service mains. On the other side of the dials is a plug switch for making the appropriate connections of the "current coils" of the test meter, for obtaining a full load through the latter in testing service meters of various capacities. This test meter contains a single series field winding, made up of a number of sections which may be connected in series-parallel groups of different capacities by means of the plug switch.

The step-bearing of the Westinghouse portable standard integrating wattmeter is of the well-known ball-jewel type, with a one-sixteenth-inch polished-steel ball between a pair of cup-sapphire jewels. On account of the small mass and short-up-and-down "play" of the rotating element, it is considered unnecessary to provide any "lacking device" for this test meter.

As indicated in Fig. 17, the test meter is really double in construction, having two complete magnetic systems, each comprising a shunt and a series field, at right angles to each other.

Cable-Hauling on the New Manhattan Bridge.

The four huge cables that will support the new Manhattan Bridge, connecting the boroughs of Brooklyn and Manhattan, are now being hauled into place. Each cable will contain thirty-seven strands of 256 wires each, a total of 9,472 wires in each cable, which must be strung wire by wire. The enormous amount of work involved will be done by machinery driven by Crocker-Wheeler electric motors.

The stringing of the wires in each cable is accomplished by means of two traveling sheaves carried on opposite legs of an endless steel rope. Each sheave consists of a three-foot grooved wheel fastened to the hauling rope by means of wrought-iron brackets. The hauling rope is three-quarters-inch in diameter and runs above the position of the bridge cables on heavy rollers supported on uprights on the temporary footbridge. There are five of these hauling-rope supports on the centre span, two on each end span and one on each tower.

The hauling sheaves move back and forth across the bridge from anchorage to

THE HAULING SHEAVE IS ATTACHED BY WROUGHT-IRON LEGS TO A THREE-QUARTERS-INCH TRAVELING CABLE.

anchorage, a distance of 3,223 feet. They are attached one to each leg of the hauling rope so that they move in opposite directions, one crossing the bridge as the other returns.

The wire is delivered to the bridge on enormous reels or spools, weighing three

CABLE-HAULING ON THE NEW MANHATTAN BRIDGE. A VIEW FROM THE TOP OF THE ANCHORAGE.

tons each. Half of these reels are placed at each end of the bridge. The end of the wire from a reel at each end of the bridge is put over the hauling sheave at that end and fastened to the anchorage. The machinery is then started and the sheaves move across the bridge, unwinding one wire from each reel. Two wires are thus strung by each sheave every time it crosses the bridge. When the sheave reaches the opposite side of the bridge the bight of the wire is taken off and made fast to that anchorage, and a new wire hauled from that side on the return trip.

The wires are laid in temporary saddles of four grooved pulleys at each anchorage. As the hauling of each strand of 256 wires is completed the wires are bound together at intervals, and the strand is lifted from the temporary saddle by means of a chain hoist and laid in its proper place in the permanent saddle. Two strands of each cable are wound simultaneously by the two sheaves of each hauling rope.

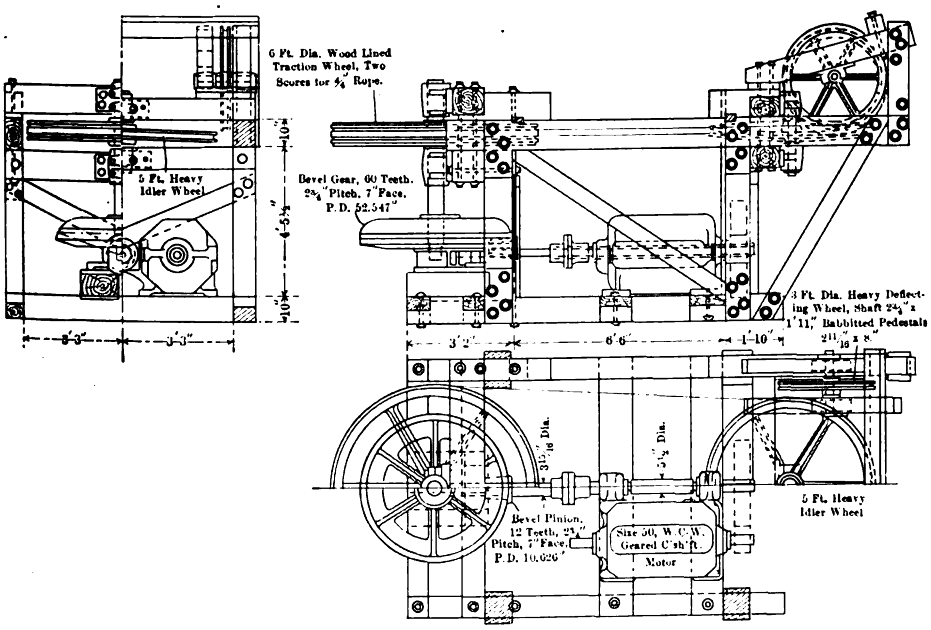
CABLE HAULING ON THE NEW MANHATTAN BRIDGE BEHIND THE MASONRY CREST ON THE BROOKLYN SIDE. THE EYE BARS ARE A PART OF THE PERMANENT ANCHORAGE.



HAULING-ROPE OPERATING MACHINERY, CABLE CONSTRUCTION PLANT, NEW MANHATTAN BRIDGE.

There is a separate hauling mechanism for each of the four bridge cables, so that they are strung independently of each other. Delays are therefore not cumulative. The delays in one cable affect that cable alone, and the work proceeds on the others. This results in a very considerable saving of time.

Each hauling rope is driven by a fifty-horse-power, 220-volt, Crocker-Wheeler, Form W motor. This is the type of motor designed by the Crocker-Wheeler Company, of Ampere, N. J., for rolling-mill duty, and is well adapted to work of this kind, where sudden overloads and frequent starting and stopping are likely. The motors are fully enclosed and capable of withstanding all kinds of weather and rough handling. The driving mechanism is shown in the illustration. Each motor is geared to a countershaft at a ratio of 5 to 1, and the countershaft is bevel-geared to the driving shaft at a 5 to 1 ratio. On the driving shaft, above the gears, is a wood-lined, grooved, six-foot traction wheel, which drives the hauling rope. A five-foot idler wheel is also provided, so that the hauling rope passes the traction wheel twice to produce the necessary grip.

The hauling rope moves at a speed of approximately 480 feet per minute. It carries the sheaves across the river in about seven or eight minutes. Allowing for the time used in attaching wires at each end, about three trips are made per hour. It is estimated that at this rate the work of hauling will occupy four months, some time being consumed in fixing guide wires for each strand and in adjusting the wires after they are hauled.

The driving motors are all located on the anchorage at the Brooklyn end of the bridge. The reels of wire, as already stated, are stored at both ends of the bridge. The wire was delivered by John A. Roebling's Sons Company, the same people who delivered the wire for the old Brooklyn Bridge thirty years ago. The work of building the cables is being carried on by the Glyndon Contracting Company, of 2 Rector street, New York city.

The hauling equipment for this bridge differs from any previous attempt. It will be remembered that in hauling the cables for the Williamsburg Bridge two steam engines were used, connected to the same driving shaft. It later became necessary to cut this shaft and use the engines independently to avoid accumulation of delays. Even with that arrangement only two cables could be hauled simultaneously. The Glyndon company's plant has double the capacity, besides being electrically instead of steam driven, with the consequent ease of manipulation and control.

CORROSION OF IRON FROM THE ELECTROCHEMICAL STANDPOINT.[1]—II.

(Concluded.)

BY C. F. BURGESS.

ADDITIONAL EXPERIMENTS SHOWING CORRODIBILITY OF STRAINED IRON.

As bearing upon the question whether strained iron has a greater tendency to corrode than the unstrained metal, the following experimental observations may be of interest. These are abstracted from a compilation of results recently obtained by John Thickens, in the applied electrochemistry laboratory of the University of Wisconsin, and also from work carried on under a grant from the Carnegie Institution.

Test rods of mild steel were treated as follows: The rods, eight inches long and three-quarters inch in diameter, were turned down at the middle section for a length of three-eighths inch to a diameter of one-half inch. These were subjected to a stress in a testing machine until the elastic limit had been exceeded and the narrow portion had necked down to a diameter of about 0.4 inch. The entire bars were then turned down to uniform diameter, this being done under running cold water to prevent heating. Bars three inches long were cut from the central portion of the longer bars, and including the strained portion. Some of these bars were subjected to corrosion by suspension in dilute hydrochloric acid solutions, and others by making them the anode in neutral solutions of ammonium chloride and causing current to flow under low current density. In all cases a marked difference was noted in the rate at which the strained portions corroded as compared with the unstrained, and although the sample looked absolutely uniform before corrosion the decrease in diameter of the strained portion after corrosion is marked.

Differences of potential of from five to nine millivolts were noted between two electrodes, one of which constituted the strained portion and one the unstrained.

Another set of samples were strained beyond the elastic limit by torsion. The original bars were three inches by one inch by one inch; they were turned down for a length of one inch at the centre to a diameter of five-eighths inch, the ends being left square. They were subjected to a torsion through 180 degrees, after which the entire length was turned down to a uniform diameter, the specimen in this condition having a uniform appearance on the entire surface. Three grades of iron were employed and are designated by the terms wrought iron, mild steel and electrolytic iron. The last one was prepared from electrolytic iron which had been melted and forged.

These were subjected to corrosion by suspension in dilute acids, as well as by making them the anode in neutral solutions and corroding electrolytically, using a low current density. In all cases a greater corrodibility of the strained metal was noted, as shown by the reduction in diameter, as well as by the general appearance of the corroded surfaces. The greatest difference was noted in the mild steel; it was less marked in the wrought iron and least with the electrolytic iron.

The more rapid electrolytic corrosion of the strained portion appears to be due to the fact that the strained metal is electropositive to the unstrained, the current finding the easier path through the surface of the electropositive metal. Another phenomenon which points to the fact that the strained metal is the more electropositive is noted in immersing the machined test samples in dilute hydrochloric acid. There is a liberation of hydrogen bubbles on the unstrained portion. This is not a temporary condition, but it persists, and indicates that there is electrolytic action, the strained portion serving as the anode and the unstrained as the cathode. It was noted that the purer the iron the less pronounced are the phenomena, and in the case of the electrolytic iron the corrosion as well as the distribution of the evolved hydrogen bubbles were nearly uniform.

The effect of annealing a previously strained bar was noted by heating a machined bar embedded in iron filings to a temperature of 900 degrees Fahrenheit for five hours. The difference in corrodibility between the strained and unstrained portions was then shown to have been completely eliminated by this treatment. In the dilute acid solutions the distribution of the hydrogen bubbles was uniform.

An instance where the increased corrodibility of steel is a matter of practical importance is in the use of punched metal. It is a universal specification in boiler construction that the rivet holes shall be drilled and not made by the cheaper method of punching. The reason for this is that the former method gives better results as far as durability and freedom from corrosion are concerned. In addition to the liability of cracking or otherwise mechanically damaging the metal surrounding the punched hole, it has been found that rivets inserted in punched holes tend to become loose and leaky.

In the process of punching, straining both by compression and tension is produced, the punched disc being compressed and the walls of the hole and the disc having been subjected to tension or shearing. According to those who hold that unstrained metal is more subject to corrosion than the strained, the corrosion around a punched rivet hole will proceed some distance away from the hole; on the other hand, if it is true that the strained portion is electropositive to the unstrained, then the metal nearest the hole should corrode the more rapidly. This is a matter which is capable of settlement by experimental demonstration, and the following experiments were carried out with this object in view:

Some steel plates three-quarters inch thick were punched cold, the punchings having a diameter of one inch. The punched plates were subjected to corrosion, both electrolytic and by dilute acids. It was noted that the corrosion was most rapid on the sides of the hole and in the immediate vicinity.

Some of the punchings were attached to wires and suspended in various corroding solutions. The suspension wires and the point of contact with the iron pieces were protected from the solution by paraffine. It was shown that the sides of the cylinders had a far greater rate of corrosion than had the circular surfaces.

One of the punchings, and a piece of similar size cut from the original steel plate, were suspended as electrodes in a one-quarter normal HCl solution and connected to a mil-ammeter. The current was constant at about one-half mil-ampere for several days, the punching being the anode, and corroding the more rapidly. Similar results were obtained by immersing in a normal KCl solution, the current remaining constant at 0.75 mil-ampere. In both solutions it was noted that on first immersion the current was much higher than the constant value subsequently maintained, this decrease being due to polarization as manifested by an accumulation of hydrogen on the unstrained cathode.

Upon momentarily lifting the two electrodes into contact with the air, and again immersing, the flow of current greatly increased. By blowing air through the solution a similar result was attained, and by adding a very small quantity of sodium

[1] From the presidential address before the American Electrochemical Society, Albany, N. Y., April 30.

peroxide the current quickly rose from 0.75 mil-ampere to over thirty mil-amperes. The effect of oxygen in all of these cases was apparently due to its depolarizing action on the cathode, which allowed more current to flow, and which consequently increased the corrosion of the strained-metal anode. This appears to be in confirmation of the important discovery made by W. H. Walker that oxygen causes oxidation, not by uniting with the iron, but by depolarizing, and allowing other corrosive agents to become active.

The experiments which have just been described are qualitative rather than quantitative, but show in an apparently conclusive manner that strained metal does have a greater solution tension than the unstrained. The results are of technical as well as of scientific interest, and the effects are so pronounced that it appears obvious that our available methods of measuring the differences of potential between strained and unstrained iron when properly applied should yield accurate quantitative data. Further quantitative measurements appear to be desired.

INFLUENCE OF INEQUALITIES OF TEMPERATURE UPON THE CORROSION OF IRON.

As bearing upon the influence of temperature upon the corrodibility of iron, there are presented here the results of some work carried on by S. G. Engle and the writer. These results are more fully described in a thesis by S. G. Engle entitled "The Influence of Inequalities of Temperature Upon the Corrosion of Iron." This investigation was originally taken up in connection with the study of certain peculiar corrosion phenomena which are commonly found in locomotive boilers.

To one familiar with the corrosion produced by stray currents in underground pipes, the pitting and grooving of boiler tubes have the appearance of being electrolytic action. A place where corrosion is particularly noticeable in locomotive boilers is just inside the end shells where the tube is expanded. At one end of the boiler a copper shim is placed between the tube and the end plate, the purpose being to utilize the ductility of the copper in making a tight joint. At the other end the tube is expanded directly to fill the hole in the end plate. If copper shims were used at both ends of the tubes a logical explanation of the fact that tubes corrode in the immediate neighborhood would be that a voltaic couple is set up between the copper and the iron. It appears, however, that the corrosion is just as marked at the end where copper is not used, and other explanation must, therefore, prevail. The one most commonly accepted is that the iron tube on being expanded is thereby strained and this strained metal corrodes more rapidly than does the neighboring unstrained metal. There is not enough data to absolutely fix this point.

There is also an irregular pitting in the tubes, the rapidity of the action depending upon the care taken of the boiler, upon the kind of feed water used and perhaps upon other factors. Among the results of this kind of corrosion are the frequent puncture of the tubes, the extinguishing of the fire, the stalling of trains between stations, and the retirement from commission of valuable machinery. The pitting may be somewhat general in distribution, but usually there are a few deep pits with the surrounding metal apparently intact. It is a matter of general observation that the pitting is more marked on the tubes nearer the shell of the boiler, rather than on those farther toward the interior—in fact, the interior tubes may last as long as several sets of tubes renewed on the lower row. This is explained commonly by the supposition that the circulation of water, also the introduction of fresh feed water, are such as to emphasize corrosive action.

The object of the investigation previously referred to was to determine if possible whether the equivalent of galvanic cells is established in locomotive boilers, due to inequalities of temperature in the different portions. The most highly heated metal in the boiler is the tubes which are exposed to the hottest products of combustion. The lower tiers of heated tubes are probably subjected to this heat. The direction of the flow of heat is from the interior of these tubes to the water, which in turn is in contact with the cooler shell of the boiler. If the boiler tube is, by being hotter, rendered more electropositive than the boiler shell, we would expect a galvanic action resulting in the corrosion of the tube. We would expect the corrosion to be at such places as the current finds the most ready path between the anode and the cathode. The shortest path between the hot anode and the cooler cathode would be between the lower and the side tubes, and the interior of the boiler shell.

An interesting peculiarity in the electrical heating is shown in the decrease of potential which is first produced by the heating and the subsequent rise after the minimum point has been reached. This minimum was not observed in the test where the external heat was applied.

It was desired to carry the temperatures of the iron surface beyond that which was possible by the former methods of heating, and this was accomplished by bending a soft iron wire into a "U" shape, immersing it in the water and heating it by the passage of an alternating current through it. Voltage readings were taken between this electrode and another one of the same material which was not heated by the passage of the current. It was found that there were certain irregularities in the measurements, due to the fact that the wire dipped down through the surface of the electrolyte. This was remedied by passing the wires out through the bottom of the vessel which contained an asbestos stopper. Water taken from the locomotive boiler was again used as the electrolyte. It was found that the heated wire first became more electropositive, then became steadily negative as the heating progressed, until the wire became fused. This tendency for the heated wire to become negative in this case is ascribed to the fact that the wire became hot enough to oxidize when in contact with the water, coating itself with the more electronegative iron oxide.

The experiments thus far indicate decided tendency for a heated surface to become electropositive, as compared with the cooler piece of metal in the same solution. This is a condition which may exist in locomotive and other boilers, although direct conclusions could not be drawn from these experiments without recognizing the fact that these were carried out under atmospheric conditions, while the water in a boiler is usually under high pressure.

If conclusions might be drawn from these data they would be to the effect that the presence of oxygen has a greater influence than has the presence of carbon dioxide in promoting the corrosive action. To compare the corrosive action in the solution as used in the last test to the same solution freed from carbon dioxide, this gas was expelled. Run was made on this same solution by applying heat and raising the pressure to a hundred pounds. This showed apparently that the carbon dioxide has practically no influence on the corrosion current.

The effects of the addition of various other dissolved substances were observed; thus treating lake water with one gramme of soda ash per five gallons of water, a method commonly employed for treating boiler-feed water, gave potentials in the opposite direction, the heated tube being the cathode. This same result was found in a more pronounced way by increasing the percentage of soda ash. However, with a solution obtained from a locomotive boiler which had been treated with soda ash and in which the soda ash had been concentrated by repeated evaporation, the inner tube became the anode. The heated tube was likewise found to be the anode when using one gramme of magnesium sulphate or magnesium chloride per gallon.

It was always noted that no matter what electrolyte was used, the current gradually increased to a certain point and then decreased. It was also noted that in repeating tests without otherwise changing the solution, the successive results always gave lower values of current and pressures. In other words, a fresh solution always causes apparently a higher current and more corrosion than one which has been used. This would coincide with the general belief that it is the fresh feed water in boilers which has the greatest corrosive action. This fact, and the one that each curve shows the current to reach a maximum, after which it decreases, even if the heat be kept constant, require an explanation. Among the suggested explanations is the influence of the formation of a high resistance coating on either the anode or the cathode, formed from corrosion products, and a second factor might be the partial decomposition of the electrolyte or a decrease of such materials in the electrolyte as might promote corrosion. For example—the presence of oxygen acts as a depolarizer at the cathode, and facilitates the flow of current as long as there is any oxygen present. It is natural to expect, therefore, that as the oxygen in the boiler water is eliminated, either by escaping with the steam or uniting chemically with other materials, the polarization will increase, and consequently the measured voltage and current will decrease.

That both of these factors apply in part should undoubtedly be recognized. From the testing apparatus the tube was removed at frequent intervals and in all cases a coating of more or less adherent scum or incipient scale was observed. Upon removing this and again making the test an increased current was noted. An examination of the surface of the tube after various runs revealed the fact that the corrosion had not been uniform but was in the form of pits which could be readily distinguished by the naked eye.

W. H. Walker has given us his opinion that the presence of oxygen in a solution promotes corrosion by acting as a depolarizer and in this way allows a more ready passage of galvanic or corroding currents. His views can undoubtedly find confirmation in the study of boiler corrosion, for it has been repeatedly noted that water which has been thoroughly saturated with air and consequently with oxygen, is especially corrosive when used as feed water. In fact, some of the most injurious cases of corrosion can be found where distilled water is used, distilled water having been allowed to become saturated with oxygen from the air.

The question naturally arises, "Do the currents, as measured in the tests referred to, reach a sufficiently large value to indicate a serious amount of corrosion?" Various of the laboratory tests have shown current of 0.01 ampere. In twenty-four hours this is equivalent to a corrosion of one-quarter gramme of metal; and since this corrosion is not evenly distributed but is confined to a few localities, it is obvious that these laboratory experiments will give basis for the belief that pitting of locomotive boiler tubes is galvanic action, and that the galvanic action is sufficiently rapid to cause perforation of the tube in a few months, or weeks, or even days.

Chicago Telephone Company to Distribute Stock Dividend.

Announcement is made that the directors of the Chicago Telephone Company have decided to distribute a stock dividend of $4,500,000 among the shareholders, the amount to be deducted from the corporation's surplus and reserve accounts of $7,332,038. It has, as well, provided for the authorization of $15,000,000 five per cent first mortgage bonds, which are to be issued in the future for construction and extension purposes. The new stock will be issued October 10, in the ratio of one share of new stock for each five shares of present holdings.

In view of the stock dividend, which will increase the company's capitalization to $27,000,000, the next quarterly dividend, payable December 31, 1908, will be two per cent, instead of two and one-half per cent, as heretofore, and it is proposed to maintain the rate of eight per cent per annum thereafter. It has been decided to finance the company's construction wants for the time being through the sale of first mortgage five per cent bonds. The proposed mortgage of $15,000,000 will be on the property as it stands at this time.

LIGHTNING PROTECTION.[1]

BY E. E. F. CREIGHTON.

During the past three years—in fact, during the past five years—very extensive measurements, starting first in the laboratory and then finally carrying the methods to the line, have been made on the conditions of lightning existing on power circuits. During last summer the entire time was spent at the plant of the Animas Power and Water Company, in Colorado, where they have vicious storms practically every day during the season. The frequency of cloud lightning was measured, and was found to be in the neighborhood of about one million cycles per second. The frequency of the discharge from an idle line was also taken and found to be about 3,000 cycles.

Next, current was not measured but was indirectly calculated from other tests, and it was possible to predetermine just how many amperes of lightning current would flow for every volt on the line. Another interesting point was, What was the voltage induced on the line? We have made no tests on direct strokes of lightning, because it is so very difficult to get them; they occur infrequently, and when they do occur it is best to be out of the way. So the only tests we made were on the induced strokes, and we found potentials momentarily on the line as high as several hundred thousand volts—between 300,000 and 500,000 volts.

The next thing we measured was the quantity of electricity that was in the stroke. That, of course, varies with every cloud and with the relative position of the cloud and the line. The last thing we measured was the duration, and that is a most important thing to know. The ordinary lightning stroke will have a duration of about one one-hundredth of a second; but the trouble is not in the actual duration of the stroke, but in its recurrence. We found numerous cases where a stroke of lightning would come from the clouds and within a second there would be seven successive strokes which would extend over a complete circuit. That is the cause of some of the failures of the multi-gap arrester.

There are a great many causes of the high-potential surges on the line; most of these can be considered due to conditions. The first is the direct stroke of lightning. In the cities a direct stroke of lightning very seldom hits a line; it hits a tree or a building somewhere near, and

[1] Abstract of an address before the Ohio Electric Light Association, Put-in-Bay, Lake Erie, July 27.

there is an induced stroke on the line. Therefore there is no protection for direct strokes of lightning for this reason, that the lightning goes to ground within a very short distance, say within seven poles from where it strikes, and there is not one chance in a thousand that a lightning arrester would be situated at that point.

Then the next question is, whether the lightning arrester would take care of the discharge if it were at that point. It would not be economy to design a lightning arrester to do that, because one could not afford to pay for it. It would be so expensive that it would cost as much or more than the apparatus that it was protecting. The only protection that can be given against a direct stroke is to install an overhead ground wire and ground it frequently. Now that is quite unnecessary in the cities, because the same kind of protection exists in the telephone wires if they run above the power lines, and in the trees and buildings that often overhang the line.

The second kind of a lightning stroke is the induced lightning stroke which comes from the cloud being over the line and inducing a static charge on the line, and discharging at some point near the line. That is a problem that is quite easy to take care of and which is pretty well taken care of at the present time by the multi-gap arrester. The multi-gap arrester in its latest improvement has two or three paths to ground so that it can take care of lightning of a different quantity of electricity—different intensity. The only thing that this multi-gap arrester can not take care of is the multiple strokes just mentioned. Occasionally it will be found that the multi-gap arrester blows up and goes to pieces when lightning is induced on the line, and in most of the cases it has been found that this is due, not to the inefficiency of the arrester, but to the local condition of the circuit.

The third condition on the line, and it is the most important and the hardest one to take care of, will be due to an accidentally grounded phase; for example, the breaking of an insulator so that the arc can play from the line to the pin, or from the line to a green branch, or from the line over to the bushing of the transformer which is grounded. These are the three conditions usually met which are hardest to take care of. Every time that the arc jumps from the line to the insulator—and it does it every half cycle as a rule—there is a surge set upon the other phases of the system which will tend to make it discharge through the internal windings or bushing or insulator elsewhere. In so doing it will cause a short-circuit; of course, an interruptcd circuit. It is far better to interrupt it than to let it play, because of the damage which may occur internally in the transformer. In this case if there is a multi-gap arrester on the circuit and it is designed to take care of the discharge, it will discharge during the first break of the current, which is the half cycle of the discharge. It puts out the arc at the end of the half cycle, but again the potential goes in the opposite direction and starts the arc again, the surge is re-established on the circuit again and the multi-gap arrester discharges. Now the multi-gap arrester can not be designed to carry the current continuously at any commercial cost figure; consequently, under those conditions the multi-gap arrester must necessarily be destroyed. The only lightning arrester that can take care of that condition is the newly developed aluminum arrester.

The fourth condition likely to be met with is something that has come up quite recently and that seems to occur on motor circuits; for example, in a large building where a direct current is operating electric motors for elevators and other purposes. If the load in the building becomes so great that a fuse blows, then that circuit is disconnected from the main circuit, with the meter on the inside, and sometimes the motor fields discharge through the meter and raise the potential, and in that way destroy the meter. If there is a heavy current flowing through a motor and the circuit is suddenly broken, it amounts to exactly the same thing as an induction coil, and the voltage depends entirely on how quickly the circuit is broken. If the fuse breaks the circuit very quickly a very high rising potential results. The protection for that is a direct-current type aluminum arrester.

These then are the four kinds of lightning potentials or surges that usually have to be met: First, a direct stroke of lightning; second, an induced stroke from a cloud; third, an accidentally grounded phase, and the fourth is the inductive kick from a motor circuit through such an apparatus as a meter.

Just one word about the aluminum arrester and the principle that it works upon. There are two forms now that are out, one for alternating current and the other for direct current. The alternating-current arrester consists of a series of cells made up from inverted cones, one inside of the other and separated by fibre washers. Between each cone is poured in a certain amount of electrolyte, making it about half full; then the whole mass is immersed in a tank of oil, the oil having two qualities: first, that of insulating the parts that are not in the electrolyte, and, second, cooling off the surface so that the arrester may operate for a long time. The characteristics of the aluminum cell are the same as the characteristics of the arrester, the arrester being made up of multiple cells. With a 300-volt circuit there would be one cell; with any higher voltage than that the total voltage between the line and ground divided by 300 would give the number of cells that would be placed between the line and ground, or the line and neutral, according to the conditions. The characteristic of each cell is very similar to a storage battery on a direct-current system. The aluminum plate surface goes through a chemical process by which a film is formed of very great thinness. It gives the surface a slightly whitish appearance. This film bears much the same relation to the circuit as does the counter electromotive force in a storage battery floating on the line. With a single cell on a 300-volt direct-current circuit the leakage is reduced to a very small volume; the cell is connected directly to the circuit and left on the circuit. The leakage of current will be about 0.001 of an ampere, but for every volt of pressure-rise above 300 the cell will allow current to flow through it equal to the excess voltage divided by the resistance. Since the resistance is very low, about one-quarter ohm, this means about an ampere for every volt, the arrester acting in all respects as a safety valve on the system. At normal pressure there is practically no discharge, but for abnormal pressures the valve opens up (there are myriads of them on the surface of this aluminum plate), allowing the electricity to flow through. In a direct-current cell the ratio of the current between normal potential and double potential is about one million; in other words, the current increases from 0.001 ampere to 1,000 amperes. So far as can be seen in the study of lightning, this is sufficient to take care of any kind of a discharge that may come on a circuit.

In the alternating-current lightning arresters, made for voltages from 2,300 volts to 110,000 volts, a gap is placed in series in order to prevent the wearing of the plates by the constant action of the alternating current. The alternating current wears the plates very much more rapidly

Storage-Battery Regulation of a Sixty-Cycle Alternating Load.

During the recent reconstruction of the Madison avenue power-house of the Elmira Water, Light and Railroad Company, Elmira, N. Y., there was installed a Gould regulating battery system embodying several novel features.

This plant supplies all the electrical power for Elmira and vicinity, which, in addition to the incandescent and arc lighting, consists of direct-current railway, direct-current power, alternating-current power and high-tension alternating-current power to interurban and suburban railway substations. The power is generated at 2,200 volts, three-phase, sixty cycles (with the exception of some of the old equipment held as reserve only), and the problem presented was to regulate the various fluctuating loads so that they could be carried by the generators supplying the lighting circuits without rendering this service unsatisfactory or requiring the operating of additional capacity to carry the momentary peaks.

In order to obtain advantage of the staggering of the peaks on the various fluctuating load circuits, the entire fluctuating load was concentrated on an auxiliary bus, the direct-current load being supplied through rotary converters, and treated so far as the regulation control was concerned as an alternating-current load, as shown on fundamental diagram of connections (Fig. 1).

The battery installed consisted of 280 cells of the Gould Storage Battery Company's type S-615 in type S-623 lead-lined tanks, having a discharge capacity of 560 amperes for one hour (ultimate capacity when the tanks are filled of 880 amperes for one hour), and capable of delivering momentary discharges up to three times the one-hour rate (Fig. 2).

This battery in series with a 140-volt, 600-1,700-ampere booster driven by a 2,200-volt, three-phase, sixty-cycle induction motor, is connected across the direct-current railway buses, the same being supplied from the variable-load alternating-current bus by transformers, and a 750-kilowatt, 600-volt rotary converter. The field of this booster is automatically controlled by an exciter set. The operation of this set is identical with that commonly employed on direct-current regulating systems with the exception that an additional machine is added in order to remove the influence of any changes in the direct-current line voltage, and that the usual regulating field-winding is replaced by a fine-wire winding controlled by a Gould regulating converter. This converter, which is driven by a small synchronous motor (Fig. 3), is fed by a series transformer placed in the totalized variable-load connection, and delivers a direct-current output proportional to the true energy component of the current in the alternating circuit. An auxiliary series transformer with sectional secondary taps brought to a compensator head mounted on the switchboard is connected in the alternating-current leads of the regulating converter, thus providing means for changing the effective ratio of the series transformer and permitting the average load supplied to the variable-load bus to be changed at will. It will be seen that the action of this system corresponds exactly with that of the usual direct-current system, the series transformer, compensator and regulating converter taking the place of the shunts and adjusting switches of the direct-current system. Any increased

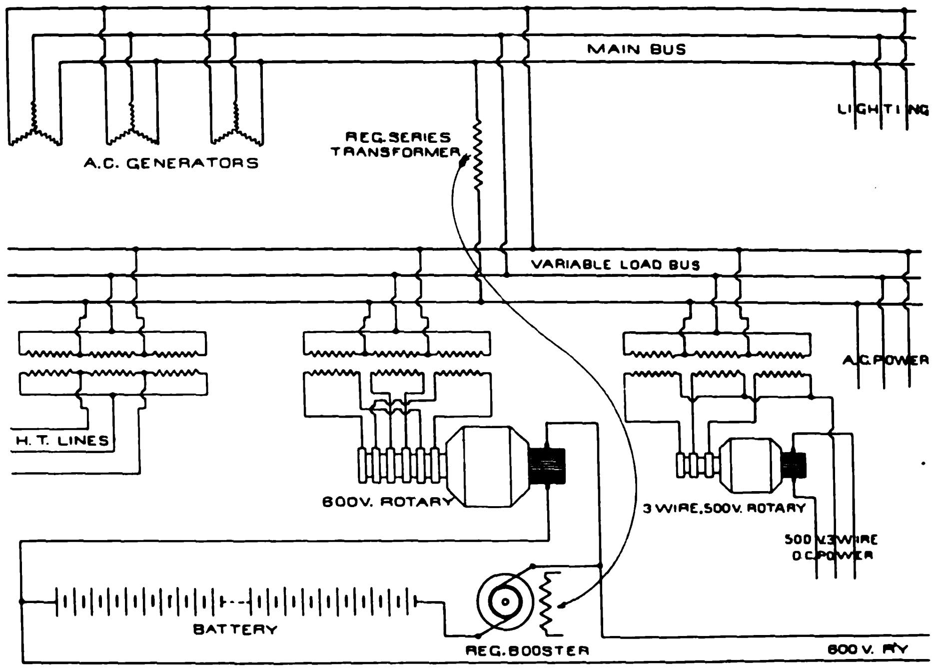


Fig. 1.—Diagram of Fundamental Connections, Elmira Water, Light and Railroad Company, Elmira, N. Y.

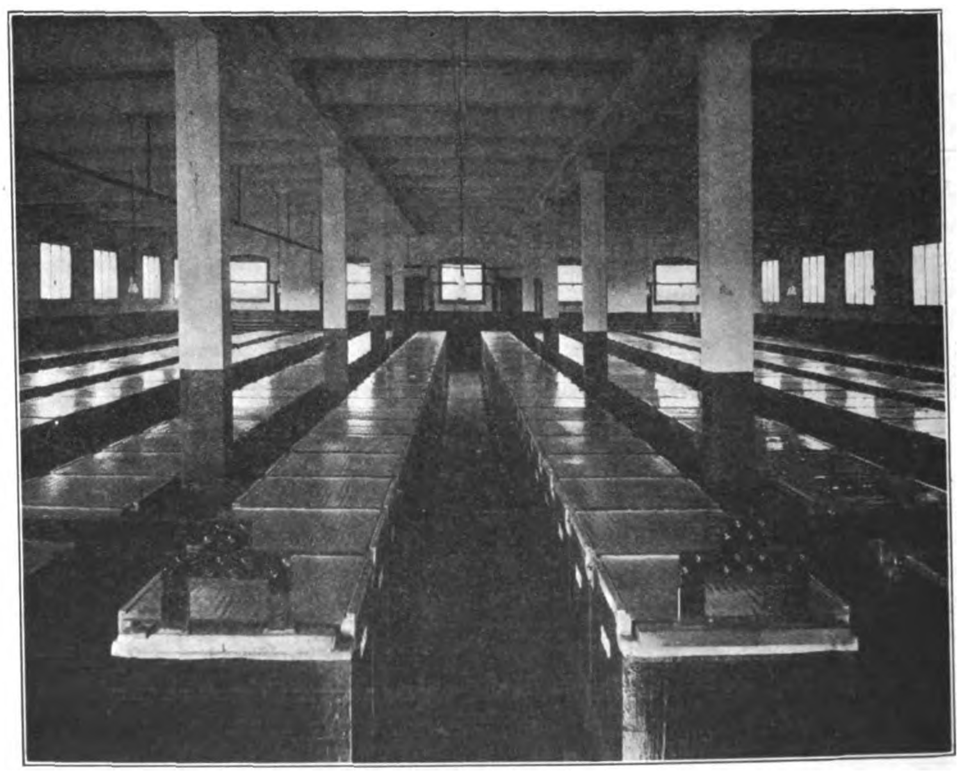

Fig. 2.—Battery Room of the Elmira Water, Light and Railroad Company, Elmira, N. Y.

demand for true energy on the variable-load bus causes an increased output from the series transformer in phase with the voltage wave, thus increasing the direct-current output from the regulating converter and causing the battery to discharge, or to charge when the demand on the bus falls below the average for which the adjustable transformer is set.

As long as the demand on the direct-current feeders is greater than the battery discharge, the action of the battery is to relieve the station of a portion of the direct-current load, the battery discharging directly to the direct-current feeders and reducing the load on the rotary. When the load conditions are such that the battery discharge is greater than the direct-current demand on the station, the battery first supplies the entire direct-current load and then inverts the surplus through the rotary and transformers to the 2,200-volt, three-phase bus. The ordinary peaks on the station do not require this actual inversion, the same only taking place at times of heavy peaks on the outgoing alternating-current feeders with a low average load on the variable-load bus, thus giving the alternating regulation with only an exceptional inversion and omitting the losses that would be incurred by a double transformation. The duty required of the rotary is approximately the same as operating without the battery, the peaks being slightly less with the battery in use.

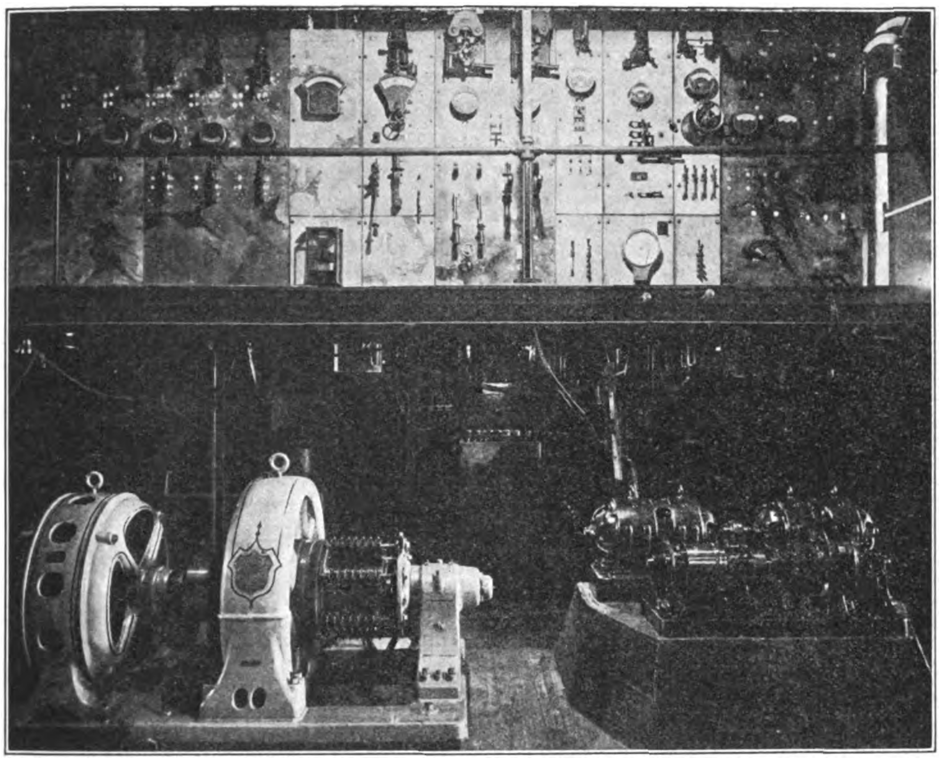

Fig. 3.—Regulating Apparatus, Elmira Water, Light and Railroad Company, Elmira, N. Y.

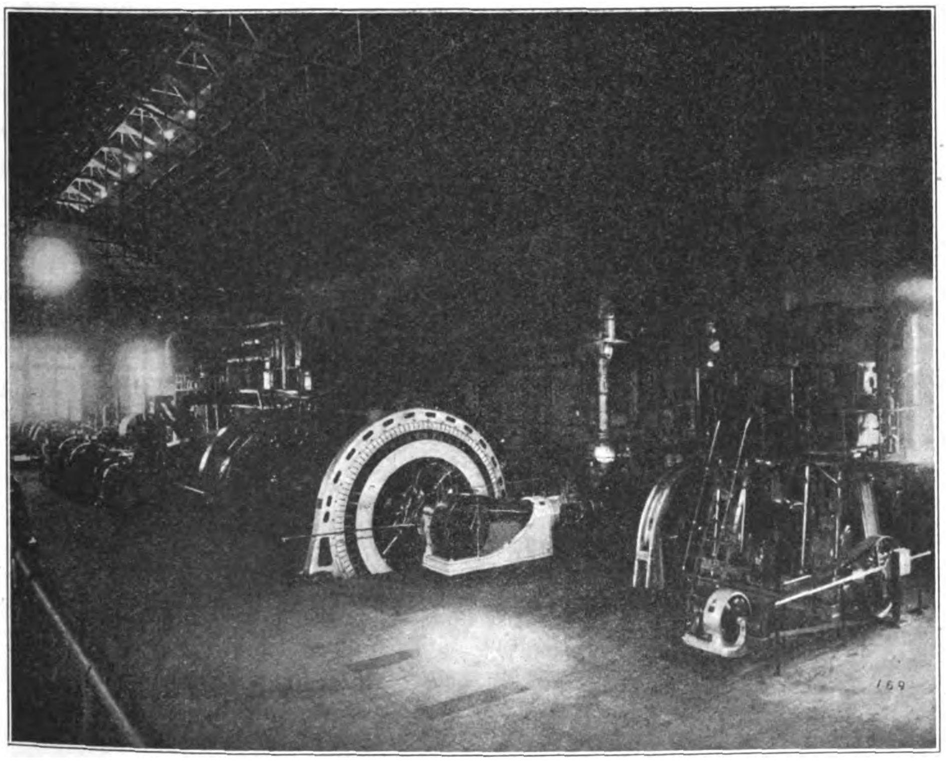

Fig. 5.—Interior of Power-House, Elmira Water, Light and Railroad Company, Elmira, N. Y.

This plant has been in successful operation for several months, the energy supplied to the variable-load bus being held constant within the limits of plus or minus four per cent, thus permitting the variable load to be carried as a steady "lighting" load, and at the same time the connections used eliminate the probability of any of the lighting energy passing through the battery and converting apparatus and thus reducing the effective capacity of the same or increasing the losses by unnecessary storage.

Association of Car-Lighting Engineers.

A meeting was held in Chicago, Ill., on August 24 and 25, to form the Association of Car-Lighting Engineers. The date for the first annual meeting was fixed for November 18, in Chicago. Committees were appointed to report on the subjects of illumination, wiring, connectors, lamps, organization, history of electric lighting on steam railroads, axle lighting, straight electric lighting, storage batteries, straight storage-lighted cars, head-end systems and entertainment.

The following officers were elected: President, A. J. Farrelly, Chicago & Northwestern Railway; first vice-president, E. M. Cutting, Southern Pacific; second vice-president, A. J. Collett, Union Pacific; secretary, G. B. Colegrove, of the Illinois Central.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

WESTERN UNION TELEGRAPH COMPANY.

The preliminary estimated statement of the Western Union Telegraph Company for the quarter ended September 30 gives net revenue of $1,700,000; bond interest, $433,062; balance, $1,266,938; dividends, $497,789; surplus, $769,149.

UNITED ELECTRIC SECURITIES COMPANY.

The United Electric Securities Company has issued a statement of earnings for the six months ended July 31, as follows: Bond interest received and accrued, $160,817; interest on notes, bank deposits, etc., $9,435; dividends received, $1,352; total earnings, $171,604; collateral trust bond interest, $99,065; expenses, $16,225; total charges, $115,290; net profit from income, $56,314; profit from sale of securities, less adjustments for discount on collateral trust bonds bought and sold, $17,691; six months' surplus, $74,005; profit and loss surplus, $1,291,677; preferred stock dividend, $35,000; surplus, August 1, $1,256,677.

EDISON ELECTRIC ILLUMINATING COMPANY OF BOSTON.

The annual report of the Edison Electric Illuminating Company, of Boston, Mass., for the year ended June 30 shows gross of $4,229,239; expenses, $2,690,419; net, $1,538,820; miscellaneous income, $38,442; total income, $1,577,262; interest, etc., $54,989; balance, $1,522,273; miscellaneous charges, $125,368; balance, $1,396,905; dividends, $1,390,796; surplus, $6,109; total surplus, $247,219.

UNITED TRACTION COMPANY.

The United Traction Company, of Albany, N. Y., for the quarter ended June 30 reports gross of $498,245; expenses, $305,027; other income, $29,341; charges, $91,884; surplus, $130,675.

HUDSON VALLEY RAILWAY COMPANY.

The report of the Hudson Valley Railway Company, of Glens Falls, N. Y., for the quarter ended June 30 shows gross of $145,547; expenses, $113,252; other income, $1,149; charges, $55,886; deficit, $22,442.

KEYSTONE TELEPHONE COMPANY.

The report of the Keystone Telephone Company for the year ended June 30 shows gross earnings of $1,051,071; expenses and taxes, $539,123; balance, $511,-948; reserve for renewal and interest charges, $413,112; surplus, $98,836; previous surplus, $503,436. The surplus is equal to 5.06 per cent on the $1,936,850 preferred stock.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY.

The report of the associated Bell Telephone operating companies, not including the long-distance lines of the American Telephone and Telegraph Company, for the month of July and seven months ended July 31, shows a further growth in the company's business. The figures for the month of July are as follows: Telephone revenue, $10,014,300; general operating and maintenance expenses, $7,175,-100; net income, $2,839,200; sundry earnings, $453,600; total net earnings, $3,292,800; interest, $627,200; available for dividends, $2,165,600. The figures for the period from January 1 to July 31 are as follows: Telephone revenue, $68,-841,700; general operating and maintenance expenses, $50,599,800; net, $18,-241,900; sundry earnings, $2,963,000; total net earnings, $21,204,900; interest, $4,529,800; available for dividends, $16,-675,100.

LETTERS TO THE EDITOR.

"The Gasolene-Electric Drive for Vehicles."

TO THE EDITOR OF THE ELECTRICAL REVIEW:

In your issue of August 29, 1908, page 300, I note an editorial comment on "The Gasolene-Electric Drive for Vehicles."

Some eight or ten years ago a United States Consul's report from, I believe it was Belgium, gave an extended account of an automobile made by a Belgium firm, the essential features of which were a longitudinal shaft direct geared to the rear axle and arranged for direct coupling to a gasolene engine and an electric motor; that is, just ahead of the rear-axle gearing was a friction clutch, next ahead was an electric motor with brushes so arranged for running in either direction, and so wound as to act as a generator when running at excess speed. Ahead of this motor on same shaft was a friction clutch; ahead of this clutch a single-cylinder gasolene engine. The equipment carried a small-capacity storage battery.

The principle of operation was that the pushing of a lever forward connected the storage battery to the electric motor; that when sufficient speed was attained by the machine, automatically the gasolene engine would come into action.

The gasolene engine's normal arrangement was such as to have a speed slightly in excess of the motor, which would cause the motor to charge the storage battery; that is, at a normal running speed under ordinary conditions, the machine was driven by a single-cylinder gasolene engine direct, the excess power of same being taken up through the generator into storage battery. The slower speed was handled entirely by electric motor. In case of long, heavy roads, the rear clutch could be disconnected and generator charged from time to time.

It appeared to me at the time I saw this report that if this principle was developed by a progressive American firm, it would have decided advantages over the then used automobile devices, and I believe could be developed into a better device than is now used.

J. F. NOBLE.

Oklahoma City, September 2.

Brusio Hydroelectric Plant.

TO THE EDITOR OF THE ELECTRICAL REVIEW:

In my article entitled "The Brusio Hydroelectric Plant and Its 50,000-Volt Swiss-Italian Transmission System," published in the ELECTRICAL REVIEW for August 8 and August 15, there appeared the following inaccuracies": "There are at present installed six main units and four exciters; two main and two exciter units are of the impulse type, by Escher, Wyss & Company; four main and two exciters are of the Girard type by Picard, Pictet & Company."

The statement should read: "There are at present installed ten main units of 3,500 kilowatts' capacity each, and four exciters of 250 kilowatts' capacity each. Two main units and two exciters are of the Girard type with partial admission, by Picard, Pictet & Company, and eight main units and two exciters are of the impulse type, by Escher, Wyss & Company, Zürich, who also supplied the entire penstock equipment."

It might also be of interest to state that the further equipment of the Brusio plant will be impulse wheels, which proved more efficient. It will be remembered that the plant is operating under a head of 1,300 feet.

FRANK KOESTER.

New York, September 14.

Cost of Subways.

The subway systems now in service in Greater New York have already cost the city the sum of $54,802,944, as shown by a statement prepared by the Public Service Commission to be submitted to the Tax Department. The Manhattan tubes have required over $48,000,000 of this sum, over $3,500,000 has been expended on the Brooklyn extension, and over $3,000,000 has been used in building the Manhattan section of the bridge loop now in course of construction.

PENNSYLVANIA ELECTRIC ASSOCIATION.

FIRST ANNUAL CONVENTION HELD SEPTEMBER 8-9.

The Pennsylvania Electric Association held its first annual convention at Eagles Mere, Pa., on September 8 and 9. There were represented forty companies, including most of the principal electric lighting companies in the state, and at the time the convention was called to order there were about one hundred delegates and guests present.

After the reports of the officers and the address of the president were presented the association discussed the advisability of reorganizing on the basis of a state branch of the National Electric Light Association. The discussion was opened by W. C. L. Eglin, president of the National Electric Light Association, who outlined the scope of the association's work and the amendments made to the constitution and by-laws to allow of the organization of state and territorial branches. The subject was discussed very thoroughly by the various members present and practically all of the features of association work were treated. The unanimous opinion was expressed that there were no disadvantages in a state association immediately becoming a state branch of the National Electric Light Association, and that advantages were to be gained along all of the lines of association work. When, later, the question was voted upon it was unanimously carried that the state association should reorganize as a state branch of the National Electric Light Association, and a committee was appointed to carry out the details. L. H. Conklin, Connellsville, was elected president; E. F. McCabe, Lewiston, vice-president, and E. L. Smith, Towanda, secretary and treasurer.

There were also in attendance at this convention a number of representatives of manufacturing companies and supply dealers, and the state branch of the association has arranged for their attendance at the state conventions.

The programme arranged for embraced most of the questions that are of importance at this time, and all of the subjects were freely discussed.

The various details of the handling of the convention were excellently managed and all of those in attendance appreciated the efforts that had been made in their behalf by the officers and committees.

THE CONVENTION OF THE PENNSYLVANIA ELECTRIC ASSOCIATION, EAGLES MERE, PA., SEPTEMBER 8 AND 9.

The opinion was universally expressed that state conventions are beneficial to the companies and fill a field that can not properly be covered in any other way.

The meetings were well attended. The paper on "The Day of Distribution," by T. Commerford Martin, was well received and opened up an interesting line of discussion, particularly on overhead-line distribution, a committee being appointed to prepare specifications and instructions regarding proper construction, and to give particular attention to foreign attachments and railroad crossings. A vote of thanks was extended to Mr. Martin.

F. W. Willcox, of the General Electric Company, Harrison, N. J., presented an interesting paper on incandescent lamps, which opened up a wide discussion on this subject.

Amusements and entertainment were provided for the ladies accompanying the members. One of the enjoyable features in which all took part was a corn roast and camp fire on the shore of the lake. An informal glee club rendered college songs and a generally pleasant evening was spent, the success of which was largely due to the entertainment committee.

Water Power in France.

The Journal of the Royal Society of Arts contains an interesting report on this subject. According to this the total water power utilized in the Alps is nearly 300,000 horse-power, while the yearly average obtainable is estimated by various experts at between 2,300,000 horse-power and 15,000,000 horse-power. Power is supplied to undertakings of two kinds. The first consists of factories engaged in the electrometallurgical and electrochemical industries, and utilizing water power obtained by them on the spot for the manufacture of aluminum, calcium carbide and ferro-silicon. These at present utilize over 100,000 horse-power in Dauphiné alone. The other kind consists of enormous power stations, pure and simple, for supplying current, not only to various works in the neighborhood, but within an ever-growing area. Lyons is lighted by power from the Volta Works at Moutiers, belonging to the Grenoble Power and Light Company, which transmits 6,000 horse-power over a distance of 112 miles under a pressure of 57,000 volts, while from Lyons to Valence the whole Rhône Valley is fed by power stations situated in the departments of the Savoy and Isère. Even St. Etienne and Roanne, in the department of the Loire, will, before long, be using electricity generated far away on the other side of the Rhône, in the valley of the Drac, a tributary of the Isère. As is well known, proposals have also been made to supply Paris from the Rhône, and schemes have been got out whereby 100,000 horse-power could be thus transmitted. These are, however, merely suggestions so far, but if the present rate of progress be maintained, in a few years the whole of France will be supplied with hydroelectric power from a few distributing centres. The industrial importance of such a development would necessarily be very great.—*Electrician* (*London*).

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

The Purchase of Coal on a Scientific Basis.

Several articles have appeared recently, in the main having been criticisms of the English coal industry, and seeming to place this industry in a somewhat unfavorable light. The present article, on the question of buying coal for industrial purposes, is from the coal-seller's point of view. In the first place, the assumption that British coal merchants are averse to modern methods of coal selection is considerably wide of the mark. The rule which must apply to all contract work in engineering—that the vendor must know as much about the article on sale as the buyer—holds good in coal dealing. A coal factor is very often in the position of actually having to advise a buyer as to the quality of coal to be selected, having regard not merely to the intrinsic quality of the fuel, but also in relation to furnaces or other purposes for which it is to be used. For this reason, if for no other, every British coal factor who takes his position seriously welcomes any scientific test which will help him to predetermine the performance of the coal for which it is his duty to find a market. The rock upon which the discussion appears to split is the undue prominence given to calorific value pure and simple. The chemical test of fuel is a very useful step to take, and the results of analyses should be carefully studied in selecting coal. It must be remembered, however, that what is ultimately aimed at is working performance, of which the only conclusive test is the trial of a sample ton, under ordinary working conditions, by a skilled fireman free from bias. It is pointed out that in a certain test of two samples of steam coal, the calorific value of one sample, as judged by the pounds of water raised to steam, was 13.76 pounds, while that of the latter was 13.7 pounds, both at a temperature of 212 degrees Fahrenheit. When, however, these two classes of coal were tried under working conditions, the second sample turned out, in a particular case, so much superior in result to the first that it was unhesitatingly adopted and retained. This might be explained by the difference in nature of the two coals and the particular requirements of the furnaces in which they were used. To require that all the coal should come from the same seam of a colliery is unreasonable. If a colliery is working one seam only, it is quite reasonable to stipulate that coal alone from that seam is secured. If, however, it is getting its output from two or three seams at different levels, it is nearly always found that the coal from these seams is mixed at the pit mouth, and the various qualities sent out are products of various seams.—*Abstracted from the Electrical Review (London), August 28.*

Telegraphy and Telephony Over Electric Light and Power Circuits.

An arrangement permitting the use of electric light and power circuits for telegraphy and telephony has been invented by Professor R. B. Goldschmidt, of Brussels. Results obtained by him over 110 or 220-volt lines are said to be equally good. The circuits may at the same time supply any number of electric lights and motors without the slightest disturbance. The transmitting device comprises a sensitive and powerful microphone, capable of withstanding currents of great intensity, which is connected in the circuit of an accumulator, a coil of thick wire and an adjustable resistance for regulating the intensity of the currents through the microphone. The coil forms the primary of a transformer, the secondary of which contains a great number of turns of fine wire of sufficiently high resistance to make the insertion of additional resistances unnecessary, when the secondary is connected to the electric light or power line. When the microphone is spoken into, the voice produces in the secondary circuit of the transformer alternating-current oscillations, which superpose themselves on the direct current flowing through the conductors and, the direct current being scarcely influenced by alternating currents, as is well known, the latter act on the telephone at the receiving end through another transformer, similar to that at the transmitting end. The calling apparatus consists essentially of a toothed-wheel interrupter placed in the circuit, which, when rotated, produces electric currents in the transformer at the receiving end. A sensitive relay connected in the secondary of this transformer serves to establish a local circuit through a battery and bell. A condenser is connected around the interrupter for the prevention of heavy sparks. When the telephone receiver is hung on a hook, the secondary circuit is closed by the relay; when the receiver is removed, the hook rises and the telephone is automatically connected in the secondary circuit of the coil. In order to telegraph it is only necessary to substitute a Morse key for the calling device, and a Morse apparatus or sounder at the receiving end for the bell. Experiments made by Professor Goldschmidt have shown that during the day the transmission is effected as perfectly as over ordinary telegraph and telephone lines, but in the evening, when many local circuits are simultaneously opened and closed, the transmission is a little more difficult. Among the practical applications of the invention are the sending of telegraphic or telephonic messages simultaneously from a central station to a number of subscribers, and communication between central stations and electric railway cars. On account of the high resistance of the transformers the current consumed is almost negligible and the devices are not much more expensive than those ordinarily used.—*Translated and abstracted from L'Electricien (Paris), August 22.*

The Utilization of Electric Power in Salt Mines.

H. R. Speyer describes in this article the generating station which has been built for the joint use of the salt mines owned by the Nordhauser Kali Company, the Immenrode Carnallit Company, and the Ludwigshall Carnallit Company. This group of mines is situated in the midst of the Harz Mountains. The raw material is brought to the surface by electrical main winding engines, and is transmitted to the factory, a distance of some three or four miles, over an electrically driven aerial steel roadway, and is shot from the incoming trucks automatically by electrical tippers into the mills. Issuing from these in a pulverized form, it is taken by conveyers to the top of the building, where it is dropped into the live-steam-heated boilers containing a solution of calcium chloride. Here the original salt, consisting of carnallite and sodium chloride, undergoes the first chemical change. The carnallite dissolves and the sodium chloride remains in its solid state. The liquid is drawn off and pumped into large open tanks, where the potassium chloride crystallizes out. This is afterwards taken to revolving drying pans fitted with spiral blades, which discharge it in its dry state into hoppers for transmission to the stores. The remaining filtrate is put through various processes for further utilization. The final output is for commercial salts, namely, potassium chloride, magnesium chloride, potassium sulphate and magnesium sulphate. The requirements for producing the commercial salts from the raw material are such that with the exception of live-steam heating for the dissolving boilers, electricity can be used exclusively. The boring operations are carried out electrically; the pit gear, including the underground haulage and winding engines, is driven by electric motors; the transmitting aerial roadway, the tippers, the mills, the hoppers, elevators, pumps, mixing and storing gear, drying plant and cranes for loading, are in each case driven electrically. The power station, when completed, will contain five steam generating sets having an aggregate horse-power of 3,500. The output of the generating machines is controlled from a low-tension control board, while all the high-tension service is in a separate inclosed chamber. The method of control from the low-tension switchboard, including the paralleling of the generators, is by relays actuated by push-buttons mounted on the front of the board. The high-tension switches of the generator cables and of the outgoing feeder cables are all actuated by solenoid coils energized from the low-voltage continuous-current circuit, and controlled from the low-tension board. In order to minimize the risk of a breakdown, the main high-tension distributing cables are laid in pairs. These are at present, however, worked in parallel, and are controlled from one switch panel. Arrangements are to be carried out to enable each feeding cable to be dealt with separately. There are in all five pairs of outgoing main high-tension cables. The transmitting pressure is 5,000 volts. Two substations have been erected, equipped with high and low-tension feeding and distributing switch panels and with static transformers for reducing the transmission voltage to 500 and 110 volts. The former is for small power work, and the latter for the lighting circuits. The electrical equipment at the several pits is described, and an analysis made of the working costs and the excellent results which have thus far been secured.—*Abstracted from Electrical Engineering (London), August 27.*

Some Contact Rectifiers of Electric Currents.

It is not generally known, says L. W. Austin, that there is a large number of solid conductors of electricity, metallic and non-metallic, in which, when brought together so as to form a contact of not too low resistance, electricity appears to pass more easily in one direction than in the other. Most cases of this kind are too uncertain and capricious in their action to allow definite study, but silicon in contact with almost any of the ordinary metals, carbon-steel and tellurium-aluminum, all show a well-marked and fairly regular unilateral conductivity. In the investigation of these contacts the author has used two main methods of experiment. In one a direct electromotive force is applied to a contact, first in one direction and then in the other, and the resulting currents measured on a galvanometer or ammeters having resistances small in comparison with that of the contact. In the second method a known alternating current of sixty cycles is sent through a fall-of-potential wire, and the required voltages taken from sliding contacts and applied to the rectifying contact, which is in series with the direct-current meter. G. W. Packard in 1906 first announced the fact that a piece of silicon, when properly brought in contact with brass or copper, or, in fact, almost any of the common metals, is capable of acting as a detector for electrical oscillations without the use of external electromotive force. The rectifiers used in the experiments were made by embedding a piece of silicon in solder and bringing a bit of brass or steel wire soldered to the end of a flat spring in contact with it. The contact pressure was adjusted by means of a micrometer pressing on the spring from above. As some points on the silicon are more sensitive than others, the contact point is also made adjustable. For the determination of the absolute sensitiveness of the silicon-steel rectifier at high frequencies, a rectifier of rather low sensibility was compared with an extremely sensitive thermo element at a frequency of 140,000. They were connected in turn in series with a one-microfarad paper condenser for stopping the direct current, and with an inductance of 0.0331 microhenry, coupled very loosely to a second tuned circuit in which oscillations were excited. For a set of nine observations, after taking account of the reactance of the coupling coil, the readings on the galvanometer, with the thermo element, indicated a mean alternating electromotive force of 0.0336 volt. The deflection due to the silicon indicated a mean electromotive force of 0.0350 volt, according to the calibration of the rectifier for low-frequency currents. The experiment shows that there is no change in sensitiveness with frequency within the limits of accuracy of the observations. While, in general, the rectified current with silicon rectifiers flows from steel to silicon, an exception was found in a certain sample which was probably less pure in its composition than the rest of the silicon specimens used. In addition to the rectifying effect of tellurium-aluminum contacts, which appears to be thermoelectric, or at least in the same direction as the thermoelectric action, and which becomes irregular above low voltages, there is a second rectifying effect in opposition to the first, which, in general, becomes prominent only at the higher voltages. This second effect seems entirely analogous to the rectification of silicon, and is of the same order of magnitude. The author concludes that in all the cases noticed, the contact has a resistance of several ohms, as though there were a resisting film between the conductors. In all the cases, too, there is a comparatively poor conductor in contact with a good conductor, but the rectification in the cases of carbon-steel and of silicon-steel is from the good to the poor, while in tellurium-aluminum it is in the opposite direction, except for very low voltages, where another phenomenon — perhaps thermoelectric — predominates. It may be worth noting that the first effect is in the same direction as the rectified current in the aluminum electrolytic rectifier. When these surfaces are sufficiently large and the contact sufficiently close, the rectification entirely disappears. Even if the rectified currents were not opposed in direction to the ordinary thermoelectric currents, their magnitude would seem to preclude the possibility of a thermoelectric explanation. Nevertheless, the fact that the direct currents are, in general, roughly proportional to the square of the alternating currents suggests heat action. It may be that there is something of the nature of polarization and a counter-electromotive force at the contact, but if this exists no evidence of it has thus far been found. It is possible that we are dealing with the still obscure question of the escape of electrons from a conductor, and that our rectifying contacts furnish us with conditions under which the electrons pass more readily in one direction than the other; that is, that it is a case of direct, and not secondary, rectification.—*Abstracted from the Bulletin of the Bureau of Standards (Washington), August.*

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Westinghouse Manhole Transformers.

The accompanying illustrations show the transformers supplied by the Westinghouse Electric and Manufacturing Company to one of the largest electrical companies in the country employing underground distribution. The many advantages of this type of construction have led to its adoption for the entire line of

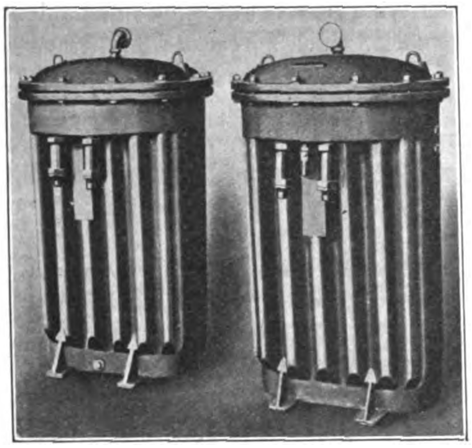

Fig. 1.—Westinghouse Manhole Transformers.

transformers designed for manhole service. These transformers are installed in subway manholes which are liable to flooding from heavy rains or overflow water, and, in addition, these underground chambers are rarely well ventilated. For this reason it is necessary to enclose the transformer in a hermetically sealed case, and design it for an exceedingly low temperature rise.

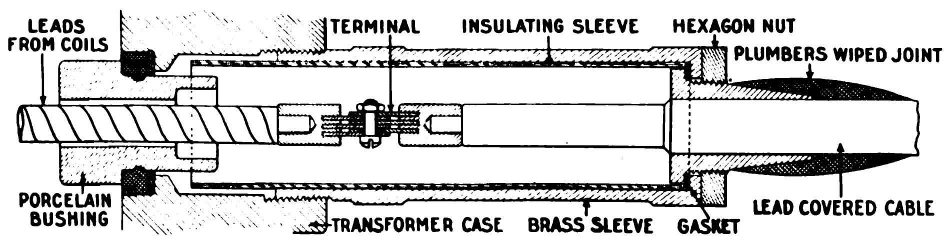

Fig. 2.—Diagram Showing Construction of Terminal Bushing.

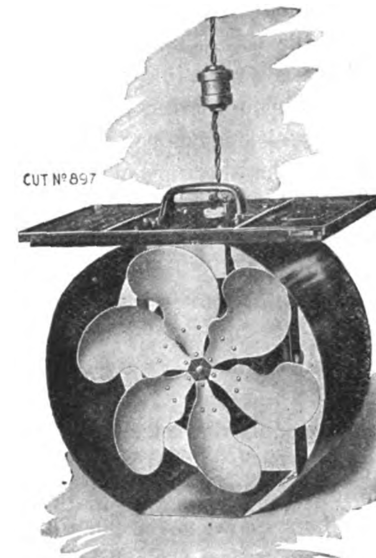
The transformers are of the oil-insulated type, and a large air space is left at the top of the case to take care of any expansion of the oil under a rising temperature. Necessarily, this compresses the air in the upper portion of the case and causes a slight rise in pressure. Under abnormal operating conditions, such as a short-circuit, a considerable rise in this pressure may occur, and the transformer case may be seriously injured. In order to avoid any danger from such occurrences a horn-shaped brass casting is used for the oil plug in the cover. The mouth of the horn is closed by a thin sheet of copper which will rupture, acting as a safety or relief valve for any excess pressures. Each case is tested with an air pressure of about ten pounds per square inch and carefully inspected for leakage before shipment.

An improved bushing is used for the leads of these manhole transformers which permits them to be connected to, or disconnected from, the line without removing the cover or otherwise opening the transformer case. This design of bushing eliminates any necessity for breaking the joints of the transformer case and eliminates the danger of water leaking into the transformer through a joint made under difficulties in the confined space available in a manhole. A further advantage of this joint, which is shown in the illustration (Fig. 2), is that it permits transformers of the next larger or smaller size to be substituted in any manhole. Three sizes of bushings cover the full line. The joint is made without any solder except that in the plumber's wiped joint required to connect the lead covering of the cable to the brass sleeve. This is a permanent connection and made when the first transformer is installed. A number of transformers of this design have been arranged to operate on a three-wire, low-tension circuit with a grounded neutral. When this method of operation is used the neutral tap on the low-tension side of the transformer is grounded directly on the transformer case through a stud terminal, as shown in the right-hand view in Fig. 1. The high-tension side of the single-phase transformer, as shown on the left of this figure, is only provided with two outlet bushings.

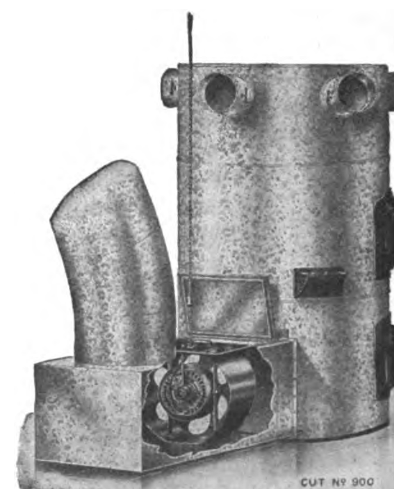
Electric Blowers for Furnaces.

The Emerson Electric Manufacturing Company, St. Louis, Mo., has developed an electric blower for use with ventilating and heating systems, adapted to either al-



Electric Blowing Unit for Furnaces.

ternating or direct current. The need is apparent for some aid to natural draft in hot-air furnaces used for heating residences, as the natural air currents from the furnace fail to properly heat one or more rooms in almost every house. Even



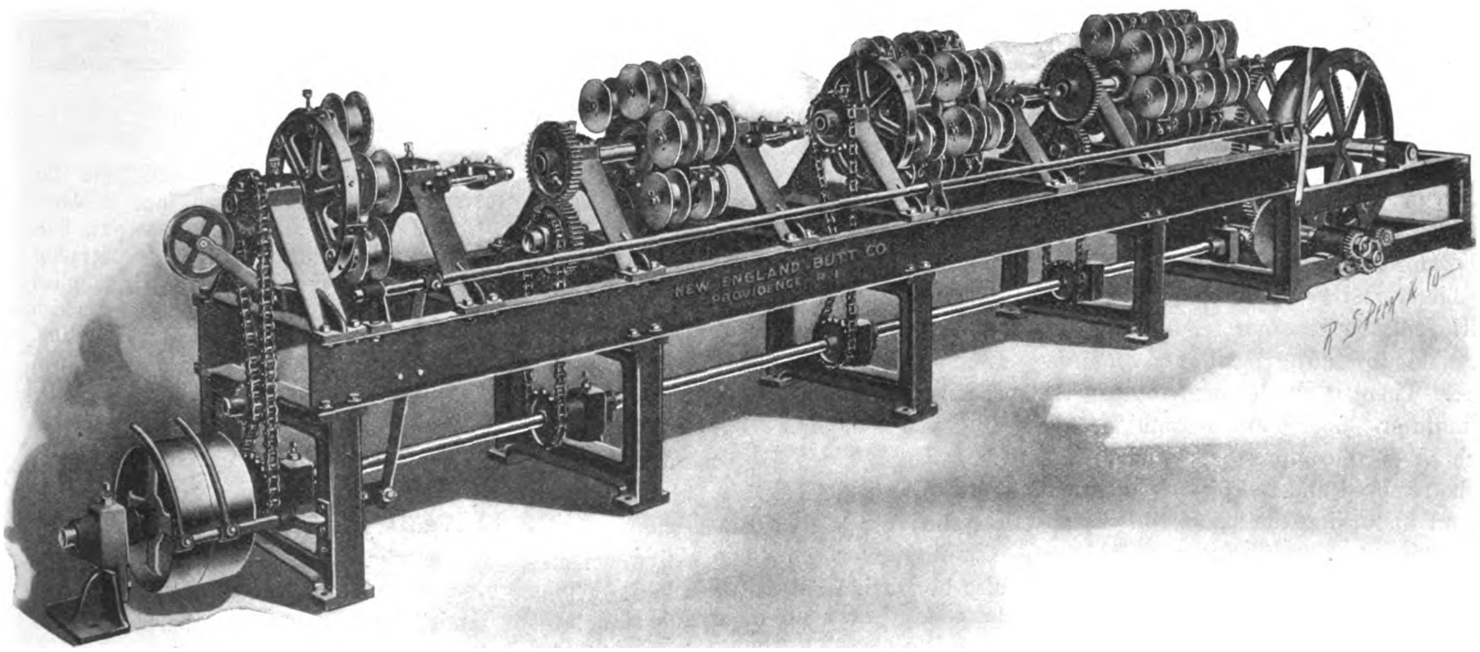
Electric Blowing Unit Adapted to Residence Furnace.

when the maximum heating power of the ordinary furnace is secured, it is almost certain that some rooms can not be kept comfortably warm. The use of the furnace blower secures a substantial increase in heat from a given quantity of fuel, forcing heated air to the rooms further from the furnace and providing greatly improved ventilation for the entire house.

In the special furnace blower shown in the accompanying illustration there has been developed a fan blower which meets all the requirements of residence service. The blower outfit is placed in the cold-air chamber of the furnace at the back of the furnace. To accommodate the motor an opening of eight and one-half inches by fourteen and three-quarters inches is cut in the top of the cold-air box and provided with a hinged lid or door. The blower outfit is complete, and may be connected by attachment plugs to any convenient electric light socket or receptacle in the cellar.

A Four-Head Tandem Stranding Machine.

The accompanying illustration shows one of the latest products of the New England Butt Company, of Providence, R. I. This is a four-head tandem stranding machine consisting of six, twelve, eighteen and twenty-four spool heads. The machine is used for making concentric cables of small sizes up to sixty-one wires. The spools, which are six inches in diameter, with a three-inch traverse, are carried on pins in such a way as to be easily removable.



FOUR-HEAD TANDEM STRANDING MACHINE.

The tension device enables the spools to be removed and inserted again without readjustment. The heads are driven by chains from the main shaft, and the alternate heads run in opposite directions. Each head is provided with die holders, adjustable longitudinally, and three sets of dies are furnished with the machine. The take-up sheave is thirty-two inches in diameter and is driven through change gearing which provides for four different lays from two to eight inches. A cross shaft on the front of the machine has a flanged pulley for driving a reel fixture.

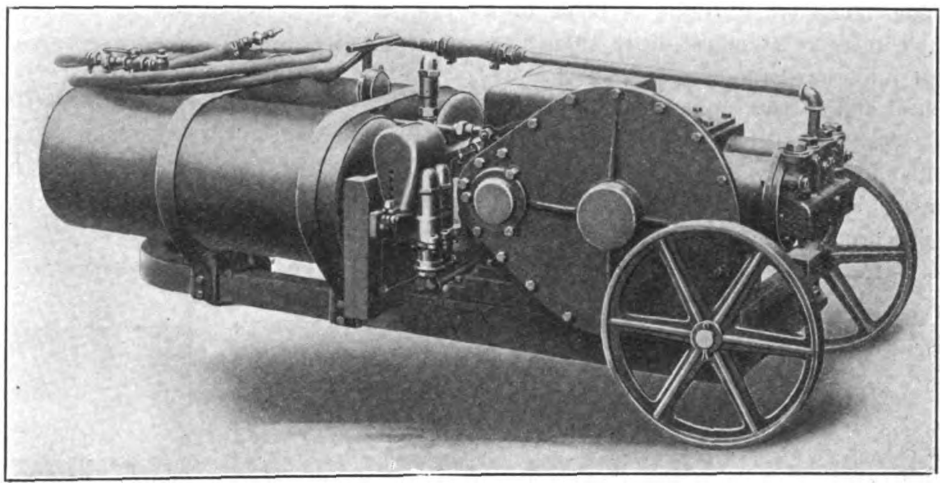
The tight and loose driving pulleys at the rear of the machine are twelve inches in diameter by three and one-half inches wide, and are run at 150 revolutions per minute. This gives the following speeds to the different heads: six-head, 175; twelve-head, 150; eighteen-head, 125; twenty-four-head, 100 revolutions per minute.

A belt-shifter is connected to a rod which runs the entire length of the machine, within easy reach of the operator.

The net weight of the machine is 23,000 pounds, and it takes up a floor space seventeen feet ten and one-half inches by two feet six inches.

A New Horizontal Blowing Outfit.

In response to the demand for a horizontal blowing outfit embracing the same general principles as the standard vertical plant, which has been in successful operation for several years, the Westinghouse Air Brake Company has designed the outfit shown in the illustration. It differs from the vertical plant chiefly in arrangement and more compact construction and is intended for use where conditions do



A NEW HORIZONTAL MOTOR-DRIVEN BLOWING OUTFIT.

not permit convenient movement of the vertical apparatus.

Portable plants are now in wide demand for cleaning electrical and other machinery, and for many services for which compressed air is the most convenient and economical agent.

The new horizontal plant consists of a motor-driven air-compressor with one or two brazed reservoirs, an electric pump governor and the usual accessories, such as switch, fuse blocks, gauge, safety valve, insulating hose connection, and hose with nozzle. The truck frame is made of a single piece of standard-shape angle iron bent into the shape of a U, and is cross-braced at the back under the compressor. The rear axle is a piece of square steel bolted directly to the frame. The compressor bed-plate bolts to the frame at each corner. The reservoirs rest upon angle-iron supports and are held firmly in place by means of wrought-iron straps bolted to the frame. A very simple switchboard is placed between reservoirs and compressor, upon which the governor, fuse blocks and switch are mounted. The position of the governor renders it easily accessible for adjustment and maintenance. There is ample room to open the commutator door and examine the brushes. The compressor cylinder head can be removed and the pistons taken out without disturbing the balance of the apparatus.

If it is ever necessary the gear-case cover can be removed by first removing one of the rear wheels, which is easily accomplished. All oil fittings are easily accessible. The rear wheels are eighteen inches in diameter, and the front wheel eight inches in diameter, and the latter can be turned through an angle somewhat greater than 180 degrees. The handle is bent so that when it lies back between the reservoirs the end of it will not protrude above the other apparatus on the truck. When the reservoirs are used they are drilled symmetrically, so that if removed either one can be put back on either side. The width of the outfit is such that it can be run through aisles thirty-one inches wide, and its height is such that it can be stored under a bench if desired. The disposal of the apparatus on the truck brings about two-thirds of the weight on the rear axle.

The type shown in the illustration can be varied in arrangement to suit conditions, and the truck furnished with roller bearings if preferred.

A Contractor's Electric Motor.

The adaptability of electric motors to all sorts of service is well illustrated in the two views herewith of a direct-current motor with a circular saw on the extended shaft. The motor only differs from a type "S" motor of standard Westinghouse design in that the shaft is somewhat larger and longer on the pulley end and that a commutator end bracket is supplied on this end to provide a bearing nearer the saw. The motor speed may be varied from 1,125 to 1,800 revolutions per minute to provide for various classes of work, with saws of different diameters. This motor is rated at ten horse-power.

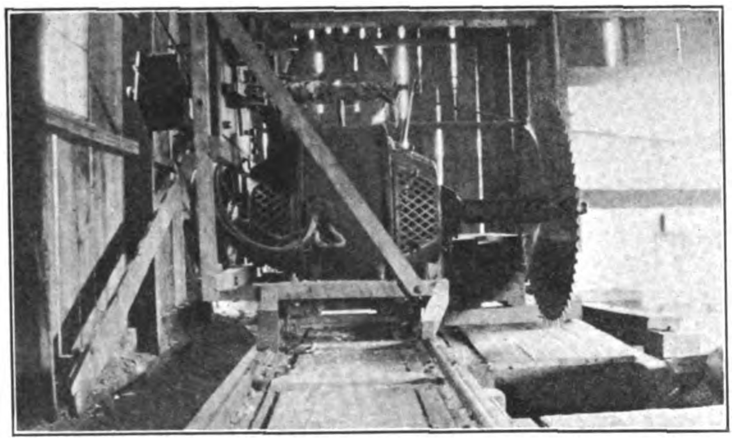


Fig. 1.—Motor Driving Rip Saw.

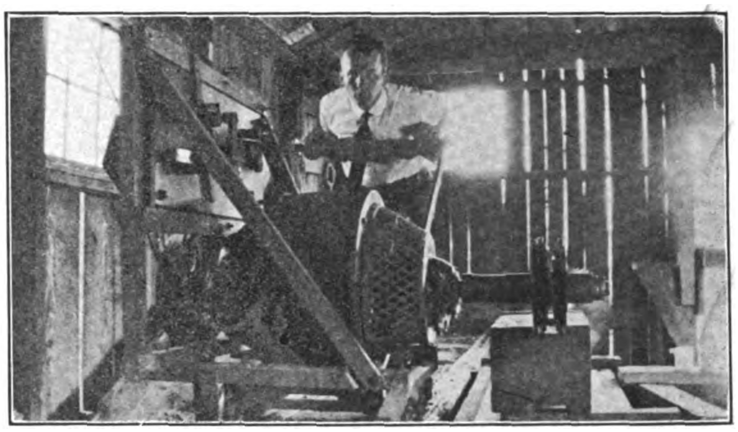

Fig. 2.—Motor Driving Groove Cutter.

It will be noted that a pulley has been installed on the extended shaft at the commutator end to act as a flywheel and also to provide a place for a brake. This latter is thrown on by means of a lever near the operator whenever it is desired to stop the saw quickly. The contractor has also installed a bladed fan on the pulley to blow air over the motor and throw the chips and sawdust away from the track and the motor. These can not be seen in the illustrations.

In Fig. 1 a large circular rip-saw is shown for taking a cut in heavy oak timber to be used in dam wickets on the Ohio River. The material must finish ten by twelve. In Fig. 2 a groove cutter is shown in place. A cross-cut saw is also used by the contractor who owns the outfit.

The motor is mounted on a frame with wheels which run on a short piece of track that the saw may be fed through the work. Attention is called to the method adopted by the contractor to keep the track clear of sawdust. In front of all four wheels a flap of leather is arranged to rub on the track which effectually clears away all material and allows the groove cutter to make a cut of even depth at all times.

Mounted on the frame which carries the motor is the switchboard panel with a field rheostat for adjusting the speed, a starting rheostat and a circuit-breaker. As the motor must move back and forth the current is supplied through two short stretches of trolley wire on which the trolley wheels run, similar to the method used in a traveling crane.

From the illustrations it is apparent that the motor is not installed under ideal conditions as the protection from the weather is none too good, but it shows to what purposes motors may be put. The entire outfit is intended by the contractor for portable service as current is supplied from a gas-engine-driven generator which is also mounted for ready handling. There is also a small air-compressor which supplies a pneumatic drill.

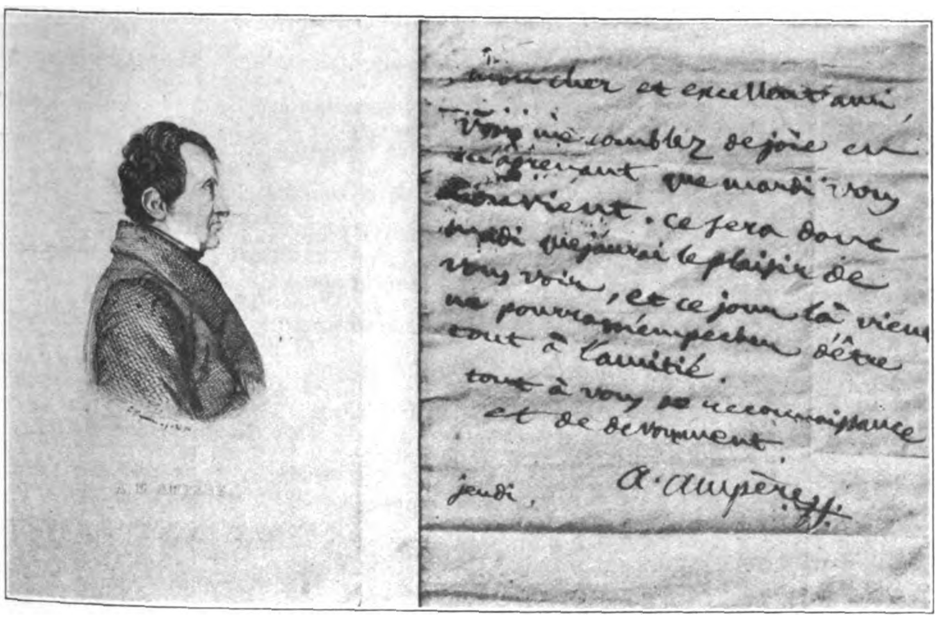
Tungsten in California.

The representative of a foreign steel corporation, says a correspondent in the *Engineering and Mining Journal,* has been some little time in the region of Randsburg and Johannesburg, in Kern County, California, examining various tungsten deposits which have been found there. Some of them, notably the Atolia, have been pretty well developed into productive mines, but most of the claims have not had any extensive work done upon them as yet. It is expected that upon the report of the expert some of the more prominent tungsten mines may be purchased by the foreigners.

Crocker-Wheeler Company Post-Office.

In order to facilitate handling the increasing volume of mail at the Ampere, N. J., post-office, the Crocker-Wheeler Company, manufacturer of electrical machinery, has built a brick and cement post-office building on its grounds. The architecture is of a modern classical style which might be termed "Federal." Upon the pediment above the main entrance is an eagle and United States shield in high relief. The interior of the building is finished in quartered oak and the floor is of mosaic tile. Upon the walls hang a fac-simile of the Declaration of Independence, with the coats of arms of the various states, a Constitution of the United States and an autograph letter and portrait of A. M. Ampere (1775-1836), after whom Ampere is named. The new post-office will still further beautify the grounds of the Crocker-Wheeler Company.

THE NEW POST-OFFICE AT AMPERE, N. J.



mon cher et excellent ami
Vous me comblez de joie en
m'apprenant que mardi vous
convient. ce sera donc
mardi que j'aurai le plaisir de
vous voir, et ce jour là rien
ne pourra m'empêcher d'être
tout à l'amitié.
tout à vous de reconnaissance
et de dévouement.
jeudi, A. Ampère

PORTRAIT AND AUTOGRAPH LETTER OF AMPERE IN THE NEW AMPERE, N. J., POST-OFFICE.

Electrical Supplies for the Navy Department.

The Bureau of Supplies and Accounts will open bids in Washington, D. C., on September 22 for 8,000 feet of telephone cable, two starting panels, six engine telegraphs, for delivery at Mare Island, Cal.; 10,000 feet of fibre conduit, miscellaneous conduit and fittings, and five engine telegraphs, for delivery at Puget Sound, Wash.; miscellaneous arc lamps and miscellaneous wire and sheet platinum for delivery at Brooklyn, N. Y.; miscellaneous electrical supplies and 1,200 steel enameled nipples for delivery at Boston, Mass.

Bids will be opened on September 29 for miscellaneous electrical supplies for delivery at Boston, Mass.; Charleston, S. C., and Brooklyn, N. Y., and for furnishing and installing three transformers at Brooklyn, N. Y.

It is announced that the Bureau of Supplies and Accounts will hereafter accept an annual bond to cover all contracts which may be awarded to one bidder during a fiscal year, instead of requiring a separate bond with each contract, provided such annual bond is executed by a corporate surety company, duly authorized under the act of Congress approved August 13, 1894, to do business as sole surety in United States matters. Blank forms and all necessary information for filing an annual bond will be furnished upon application to the Bureau of Supplies and Accounts.

The Golden West and American Industries Exhibition.

An American exposition, for which all the exhibits will be taken from this country, will be held in the grounds and buildings of Earl's Court, London, England, next year from May to October, under the title of "The Golden West and American Industries Exhibition." A distinguished committee has been organized, headed by the Lord Mayor of London. Representatives have been appointed to visit the leading cities, and all manufacturing districts of the United States, the commissioner in charge of the work being John W. Ryckman. The temporary headquarters of the commission have been established at the Ansonia, Broadway and Seventy-third street, New York city.

The exhibition will typify the great development of the states of the "Golden West" since the discovery of gold in California in 1849, and will also commemorate the bicentennial of the completion of the first Atlantic cable.

The New York Electrical Show.

The New York Electrical Show will be held in Madison Square Garden, New York city, from October 3 to October 14. Plans have been developed to create a number of startling features in the way of exhibit decoration and decorative lighting. The popular application of power will be made a feature of the coming exhibition. It is announced, also, that a series of lectures, twice daily, will be given free of charge in the concert hall.

Thomas A. Edison has signified his willingness to act as president of the exhibition, and on the opening night will be present at Madison Square Garden.

During the show the jubilee of the first Atlantic submarine cable will be celebrated, and the receipts for the evening of Thursday, October 8, will be given to the Loomis Annex.

Current Electrical News

DOMESTIC AND EXPORT.

MONTREAL LIGHT, HEAT AND POWER—A New York syndicate, headed by Leslie Shaw, ex-Secretary of the United States Treasury, has made an offer to the directors of the Montreal Light, Heat and Power Company to purchase the company. The offer is in the shape of a ninety-nine-year lease, the New York syndicate to have the right to purchase the stock at 110.

MONTANA INTERURBAN—The Billings & Cooke City Electric is being organized with $3,000,000 capital to build a line from Absarokee, Mont., northeast to Billings. Surveys are now being made and grading will begin as soon as the right of way is secured. J. B. Clayberg, Helena, Mont.; George E. Savage, Butte; A. L. Babcock, Theodore Martin and Bert G. Shorey, Billings; M. E. Estep, Chicago; Thomas Harney, Galena, Ill., and E. M. Hosky, of Helena, are interested.

NEW JERSEY RAPID TRANSIT COMPANY, INCORPORATED—The New Jersey Rapid Transit Company, with a capital of $1,000,000, has been incorporated at Trenton, N. J., for the purpose of constructing a railroad from the city of Paterson to Suffern, N. Y., a distance of fourteen miles. The incorporators are Thomas J. Maloney, of Jersey City; Henry M. Parmalee, Herbert Bogart, Charles D. Cook and Guy H. Pierce, all of Paterson; M. R. McAdoo, Montclair, and George M. Dunlap, Spring Valley, N. Y.

NOOKSACK VALLEY ROAD FILES INCORPORATION PAPERS—Articles of incorporation have been filed at Bellingham, Wash., for the Nooksack Valley Traction Railway Company, which is surveying a route for the Bellingham-Ferndale Interurban. The incorporation papers state that the purpose of the company is to run lines from Bellingham to Sumas, thus providing for both the Ferndale and Lynden branches. The incorporators are W. P. Alward, J. S. Wheeler, J. E. Morrison and W. H. Jarrett, of Seattle; Edward Brown, of Custer, and Joseph Morrison and J. William Welch, of Ferndale. The capital stock of the company is listed at $1,250,000.

WISCONSIN TRACTION PROPERTY IN HANDS OF NEW COMPANY—With a capitalization of $850,000 the Wisconsin Electric Company has taken over the property of the Winnebago Traction Company, recently sold under foreclosure proceedings. The new company has been authorized to issue $1,500,000 in bonds. The officers of the Wisconsin Electric Company are: President, O. C. Fuller; secretary, Fred C. Best; treasurer, R. C. Smith; manager, C. C. Smith. The company will operate the Oshkosh city lines and the interurban lines in conjunction with the Eastern Wisconsin Electric Railway Company between Oshkosh and Fond du Lac formerly operated by rival interests.

$10,000,000 COMPANY TO BUILD KANSAS INTERURBANS—The organization of the Interstate Railway and Power Company, which will build and operate a network of trolley lines covering eastern and southern Kansas, with a main interurban line between Kansas City and Topeka by the way of Lawrence, has been completed. With this has been organized the Kansas City Union Trust Company, a $10,000,000 corporation, which is to finance the deal. Headquarters of both companies are to be in Kansas City, and men of that city are the most active promoters of the proposition. It is announced that $8,000,000 of the proposed capital of the Kansas City Union Trust Company has been arranged by financiers of Liverpool. The remainder has been subscribed or is to be subscribed in the district where the new lines are to be operated.

KANSAS-COLORADO ELECTRIC LINE—The Kansas-Colorado Railroad Company, organized recently at Pueblo, Col., to build a trolley system in the Arkansas Valley from Pueblo as far east as Dodge City, Kas., has applied to the Kansas Charter Board for authority to engage in business in the state. The original company was chartered under the laws of Colorado and its headquarters are at Pueblo. The company says its object is to construct and operate either a standard-gauge steam or electric road from Pueblo east to Dodge City, taking in these Kansas towns: Coolidge, Syracuse, Lakin, Deerfield, Garden City, Pierceville, Ingalls, Cimarron and Dodge City. Branch lines are provided for to Scott City and other towns in that section of the state. It wants authority to build the road, electric plants and telegraph and telephone systems. Its capital is placed at $5,000,000. Most of the men interested in the concern live in Colorado. The Kansas men on the board of directors are W. P. Humphrey, Syracuse; A. C. Campbell, Lakin; Andrew Russell, Dodge City, and A. H. Warner, Garden City.

PROPOSED EXTENSION OF TRANSIT FACILITIES IN PHILADELPHIA—An ordinance providing for an increase of the city of Philadelphia's indebtedness $4,000,000, with which to build an elevated railroad from Front and Market streets to the Torresdale Boulevard, has been introduced in select council by James Emery Byram. The bill was referred to the street railway committee. The ordinance authorizes the mayor to enter into a contract for the construction of the railway from Front and Market streets to the terminal at the Torresdale Boulevard. It is provided that the city shall lease the road to the highest bidder. Funds with which the city is to build the road are to be obtained by increasing the indebtedness by $4,000,000, the loan proposition to be submitted to a vote of the people. Such a railroad would tap a territory embracing more than forty-three square miles and containing a population of more than 324,000. It would afford quick transit facilities to residents of Frankford, Kensington, Richmond, Bridesburg and the eastern side of old Coopersville, which is now the thirty-third ward.

DATES AHEAD.

American Institute of Mining Engineers. Annual meeting, Chattanooga, Tenn., week of September 29.

American Electrotherapeutic Association. Annual meeting, New York city, September 22-24.

Central Electric Railway Association. Next bi-monthly meeting, Indianapolis, Ind., September 24.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 5-6.

Empire State Gas and Electric Association. Annual meeting, New York city, October 7.

Kansas Gas, Water, Electric Light and Street Railway Association. Annual meeting, Pittsburg, Kan., October 8-9.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

Railway Signal Association. Annual meeting, Washington, D. C., October 13-15.

Order of the Rejuvenated Sons of Jove. Annual meeting, Buffalo, N. Y., October 15-16.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October 20-23.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Association of Car-Lighting Engineers. First annual meeting, Chicago, Ill., November 18.

NEW MANUFACTURING COMPANIES.

BOSTON, MASS.—The Universal Electric Light, Power and Machine Company has been incorporated to deal in electrical supplies. The capital stock is $100,000. Albert L. Farr, of Stonington, Me., is president and treasurer.

WILMINGTON, DEL.—The Automatic Cashier Machine Company has been incorporated to manufacture electrical apparatus. The incorporators are J. Charles Righter, Samuel Vance, Jr., both of Philadelphia, and Harry W. Davies, of Wilmington. The capital stock is $300,000.

ELECTRIC LIGHTING.

BELLEFONTAINE, OHIO—The West Liberty electric plant has been sold to R. M. Keller, of Washington, for $10,000.

SIOUX FALLS, S. D.—The business men and other residents of Scotland have decided in favor of an electric lighting system.

ROCKFORD, ILL.—Improvements to cost in the neighborhood of $40,000 to $50,000 are contemplated by the Rockford Electric Company.

DAYTONA, FLA.—The Daytona electric light plant, which was recently destroyed by fire, will be rebuilt. Bonds have also been voted for a city waterworks plant.

BASTROP, TEX.—The Bastrop Water and Light Plant, including fixtures for the ice factory, was sold at public sale to T. A. Hasler for $12,281.40, one dollar more than the indebtedness on the plant.

CLINTON, MASS.—The Marlboro Electric Lighting Company has entered into an agreement with the Connecticut River Power Company to secure a portion of its electric power from the plant at Vernon, Vt.

NORTH PLATTE, NEB.—The electric light company has greatly enlarged its plant within recent months, the latest improvement being the installation of a new 250-horse-power boiler and a 150-kilowatt dynamo.

LEXINGTON, KY.—The Kentucky Water, Heating and Illuminating Company, John A. Gary, president, has bought for $6,100 the franchise for a new electric lighting plant in this city, auctioned by Mayor Skain.

ARVADA, COL.—A special election has been called for September 22 at which the citizens will vote upon the matter of granting a franchise to a newly organized company which purposes to light the town with electricity.

LOGANSPORT, IND.—The contract for the new equipment to be installed in the Logansport municipal electric and power plant has been awarded to the Westinghouse Electric and Manufacturing Company at its bid of $27,907.94.

CORPUS CHRISTI, TEX.—A charter has been granted to the People's Light Company, of this city, which will at once begin the installation of a $30,000 electric power and ice plant. This will be the second plant of the kind to be installed in Corpus Christi.

SALISBURY, N. C.—The Southern Power Company is now supplying current to the Salisbury & Spencer Street Railway Company, in this city. The current is conveyed a distance of 104 miles and its use increases the capacity of the Salisbury electric plant from 600 to 4,000 horse-power.

BUFFALO, N. Y.—The Buffalo General Electric Company has built a transformer station for the purpose of delivering power and lights, both arc and incandescent, to the Lackawanna district of West Seneca. The company will tap the wires of the Niagara, Lockport & Ontario Power Company.

NORFOLK, CT.—Excavations have been begun for the foundation of a building on the site of the Southern New England Telephone Company office, which was destroyed by fire several years ago. When completed the new building will be used as a substation by the Berkshire Power Company.

BANGOR, ME.—The Bar Harbor & Union River Power Company has its line completed from the power plant in Ellsworth to Bar Harbor, a distance of about twenty-three miles. Light and power are now being transmitted from Ellsworth to Bar Harbor, and a line is being built to Bangor.

LIVE OAK, CAL.—The Live Oak & Encinal Lighting Corporation is being formed by Live Oak business men. It is proposed to run wires from the substation at Encinal along the public road to Live Oak and place lights on about every third pole that carries the wires of the Bay Counties Power Company.

BOYSEN, WYO.—Work on the dam of the Big Horn Power Company, which was suspended several months ago when a controversy as to the height of the dam arose, has been resumed. The dam will be thirty-five feet in height and will make possible the generation of 10,000 electrical horse-power from the flow of the Big Horn River.

NIAGARA FALLS, N. Y.—The Ontario Power Company is constructing an entirely new transmission line to Welland, Ontario. At the river, west of Niagara Falls, Ontario, the poles are seventy-five feet high. Three cables have been strung and three more are to be added. From the river the company has its own right of way paralleling the line of the Michigan Central Railway.

MACUNGIE, PA.—At a meeting of citizens the Macungie Electric Light, Heat and Power Company was organized. Charles H. Neumoyer was elected president of the company; Postmaster H. L. Hertzog, treasurer; W. N. Decker, secretary; Charles Boettger, H. B. Weaver, C. O. Shimer, Adam B. Neumoyer and Charles H. Neumoyer, directors. The capital stock was placed at $5,000.

TABOR, IOWA—On September 21 the people of Tabor will vote on the granting of a franchise to the Malvern Light and Power Company. This company proposes to run a wire from its plant at Malvern to supply the necessary current. It will cost the Malvern concern $15,000 to enlarge its plant for this purpose. To aid in the enterprise thirty-five citizens of Tabor have subscribed for $7,500 of the bonds.

BUFFALO, N. Y.—Plans for the proposed electric lighting system at the city hall will soon be completed by J. J. O'Leary, the electrical expert engaged by the board of trustees for that work. Mr. O'Leary and Trustees Bisgood, Zittel and Steul have returned from a trip of inspection to Harrisburg, Pa.; Philadelphia, Pa.; Washington, D. C.; Baltimore, Md.; Trenton, N. J.; New York city and Syracuse, where they examined the lighting systems of the public buildings.

WAUWATOSA, WIS.—The common council has entered into a five-year contract with the Milwaukee Electric Railway and Light Company under which the company will at once install a system of Nernst lamps. A total of 112 of these lights will be placed, with possibly twenty-seven more within a short time. The contract is for an all-night service, the city to pay $21 per lamp per year. In order to operate these lights it will be necessary for the company to rewire a part of its system.

SANTA ROSA, CAL.—At the annual meeting of the Cloverdale Light and Power Company A. Sbarboro was chosen president, P. C. Rossi vice-president, and A. E. Sbarboro secretary and manager. C. A. Feldmeyer was reappointed superintendent of the company. The work of the past year was found to be very satisfactory and it was planned to extend the lines of the company north and south of Cloverdale, and also to cross the Russian River and supply light and power for the many residences in the rural section there.

ASHEVILLE, N. C.—Extensive improvements are to be made by the Asheville Electric Company. The expenditure will amount to between $25,000 and $30,000 for new transformers, switchboards and other apparatus for utilizing the current obtained from the Weaver Power Company as well as the reserve of the steam plant. On account of the increased business of the company the new equipment will be more extensive than that which it will replace and, to accommodate it, an addition to the power-house, costing about $5,000, will be required.

FALL RIVER, MASS.—At the annual meeting of the Tiverton Electric Light Company officers were re-elected as follows: President, John R. Hicks; clerk, George R. Lawton; treasurer, Owen Durfee. Directors: Edward L. Anthony, Rufus W. Bassett, Robert S. Goff, Albert F. Dow, Frederick O. Dodge, Fall River; John R. Hicks, George R. Lawton, Tiverton. It was reported at the meeting that the work of constructing the lines in Tiverton would probably be begun at an early date. The power will probably be furnished by the Fall River Electric Light Company.

NEW PUBLICATION.

"THE FUTURE OF ELECTRICITY"—The New York Electrical Trade School has reprinted a lecture entitled "The Future of Electricity," which was delivered to the students of the school by Professor Charles P. Steinmetz in the lecture hall of the American Institute of Electrical Engineers last fall. This lecture is full of helpful and hopeful information for the younger man, and its reading will prove a decided stimulus to the student who is ambitious to succeed and become a factor of importance in his chosen profession.

ELECTRIC RAILWAYS.

KANSAS CITY, MO.—The Kansas City & Olathe Electric Railway has been completed between Rosedale and Shawnee.

MACON, GA.—The Macon Railway and Light Company is installing new machinery in its power plant in Macon. More than $50,000 will be expended.

ROCHESTER, N. Y.—The Buffalo, Lockport & Rochester electric line is now in operation as far as Albion. It is hoped to have the system completed to Buffalo by November 1.

STERLING, ILL.—The people of Tampico Township have raised the sum of $15,000 for the purchase of bonds of the new interurban line that is being proposed between Tampico and Hooppole.

LITTLE ROCK, ARK.—A 1,500-horse-power turbine engine is being installed in the power house of the Little Rock Railway and Electric Company. The new engine is one of the largest in use in the South.

MARSHALL, TEX.—Marin Turney has made application for a franchise to build an electric car line in the city. He guarantees to build one and three-quarters miles of track and to operate the same within the first thirteen months.

CAIRO, ILL.—Announcement is made that the Cairo Electric Traction Company and Cairo City Gas Company have been bought by the McKinley traction system, which will control all the public lighting and traction facilities of this city.

NEW CASTLE, PA.—James Strawhecker, of Zelienople, president of the proposed Wampum-New Castle street railway, states that he expects to begin active work in a short time. The line is to come through West Pittsburg and South New Castle borough.

DULUTH, MINN.—The Duluth Street Railway Company, now operating under a franchise which still has twenty-three years to run, has applied to the secretary of state for new articles of incorporation to extend fifty years from date, with a capital of $1,500,000.

LAPORTE, IND.—Electric cars will run direct between Michigan City and Louisville within eight weeks. The recent completion of the Laporte extension of the Murdock lines leaves but one small gap, that between Peru and Warsaw. Three cars will make the trip each day.

OKLAHOMA CITY, OKLA.—Information has been received from G. B. Stone, the president of the Chamber of Commerce, who is now traveling in Europe, to the effect that a company made up of Vienna capitalists is being organized for the construction of a trolley line from Oklahoma City to Wichita Falls, Tex.

HASTINGS, PA.—The Barnesboro Construction Company has been awarded a contract by the Northern Cambria Street Railway Company for the construction of an extension of the system from Barnesboro to Hastings. The street railway company has already invested $400,000 in its line from Patton to Barnesboro.

REDWOOD CITY, CAL.—Supposedly representing the interests of the Southern Pacific Company in its plans to spread a network of electric railways throughout the peninsula, S. M. Snyder, a realty promoter and agent for North Fair Oaks, has secured the consideration of the trustees to his plan for an electric road through the city.

CHESTER, PA.—A movement has been begun to establish a trolley line between this city and West Chester, the route of the proposed road to pass through Village Green, Concord, Thornton and Westtown. All the property owners in that section are in favor of the project. It is expected that the road will be staked out at an early date.

OKLAHOMA CITY, OKLA.—Surveys on an interurban electric line from El Reno to Oklahoma City by way of Yukon have been started. The road will parallel the Rock Island tracks between Yukon and El Reno, touch the Oklahoma City street railway system at Belle Isle and enter Oklahoma City over the local company's tracks. Maney Brothers and Henry Schafer, promoters, have applied for an increase in capital stock from $25,000 to $1,000,000. The line will be known as the El Reno Cable and Trolley Company.

GOUVERNEUR, N. Y.—A trolley road is proposed for this section of the state. A. A. Potter, in behalf of the parties interested, has circulated a petition among the business men of this village asking them to agree to give the company their freight business. The petition receives the signature of practically every firm. The right of way of the entire distance of 100 miles has been secured, and as soon as the franchise is granted a survey of the proposed route will be made and active operations on the construction of the road begun.

HAMILTON, OHIO—Stockholders of the Cincinnati Northern Traction Company have elected the following directors: George B. Cox, Bensom Fodaker, Charles Richardson, N. S. Keith and L. A. Ireton, of Cincinnati; O. V. Parrish, Peter Schwab and W. C. Shepherd, of Hamilton. The directors elected George B. Cox president, W. C. Shepherd vice-president, and F. R. Williams, of Cincinnati, secretary and treasurer.

DES MOINES, IOWA—George W. Adams, president of the Iowa & Omaha Short Line Railway Company, states that the preliminary work is well under way and actual construction on the new line will begin the coming spring. Most of the right of way has been taken and the surveyors are in the field. The line as proposed will run from Des Moines to Omaha by way of Dallas Center, Panora, North Branch, Exira, Elkhorn, Walnut, Oakland, Carson, Treynor and Council Bluffs.

ASHEVILLE, N. C.—On application of the Asheville Electric Company and other creditors, the Asheville Rapid Transit Company, on its admitted inability to meet its liabilities, has been placed in the hands of a receiver, Judge Ward appointing John P. Arthur to take charge of the property. Under order of the court the receiver will operate the railway, as at present, from the Golf Links station to Craggy station, a distance of five miles, but no effort will be made to operate the Overlook Park line from the Golf station to the top of Sunset Mountain.

BATH, N. Y.—There is a possibility that the Sodus Bay Railroad which was abandoned thirty years ago, when it was finished and ready for the rolling stock, may be constructed. Former Congressman Haines, with several capitalists and railway promoters, has been looking over the roadbed. The promoters entertain the idea that it would be feasible to build the road as an electric line. The Sodus Bay road was abandoned because several of its principal promoters yielded to the interests of the Fall Brook road, which paralleled the Sodus Bay line from Corning to Lyons.

ASHEVILLE, N. C.—Work on the construction of the electric line from Weaverville to Asheville, a distance of nine miles, is now well under way, and it is expected that the grading and trestle work will all be completed within sixty days. It is the purpose of the Weaverville Electric Company, the corporation building the road, to have cars in operation by late fall. It is learned that the promoters of the Weaverville-Asheville electric line purpose extending the line further into North Buncombe and make it penetrate the Barnardsville section and on to the Yancey county line. It is believed that the line will ultimately be extended to Burnsville, in Yancey County.

HUNTSVILLE, ALA.—A controlling interest in the Huntsville Railway, Light and Power Company is said to have been acquired by Ed. L. Pulley and his associates, who have incorporated the Huntsville, Chattanooga & Birmingham Railway, Light and Power Company. The incorporators are Mrs. Jimmie V. Lowry, of Huntsville; Dr. William J. Pulley, of New York; N. O. Wallace, of Fayetteville; Charles H. Pulley and Ed. L. Pulley, of Huntsville. Officers have been elected as follows Mrs. Jimmie Lowry, president; Dr. Wm. J. Pulley, vice-president; N. O. Wallace, secretary; Charles H. Pulley, treasurer, and Ed. L. Pulley, general manager. The authorized capital stock is $50,000, of which $31,000 has been paid in.

GALESBURG, ILL.—The Galesburg, Aledo & Northwestern Railroad Company has been organized with a capital of $10,000 to run through the counties of Knox, Warren and Mercer to the city of Aledo. The road will then proceed through Rock Island County to Rock Island, and thence to Muscatine, Iowa. The articles of incorporation call for a charter of fifty years' duration, the government of the company to be in the hands of a board of directors and such executive officers as may be provided for in the by-laws. The prospects for the line are growing brighter each day and at present practically all doubt as to the building of the road has disappeared. The subscription books will be opened and work on the line commenced in a few weeks.

PERSONAL MENTION.

MR. H. A. GRANT has assumed the position of general manager of the Orlando Water and Light Company, of Orlando, Fla. Mr. Grant has had a wide experience in the electrical field, having been identified with the Florida Electric Company, of Jacksonville, Fla., for the past seven years.

MR. C. M. NININGER has been appointed district commercial manager of the Southern Bell Telephone and Telegraph Company, with headquarters at Montgomery, Ala., succeeding Edward Lyle, who has been promoted to the position of general right of way agent, with headquarters at Atlanta, Ga.

MR. WALTER P. SCHWABE has been appointed manager of the Northern Connecticut Light and Power Company, succeeding Parker H. Kemble, who has hitherto acted as both president and manager of the company. Mr. Schwabe for fifteen years was in charge of the Rutherford (N. J.) plant of the Public Service Corporation of New Jersey.

MR. CLARENCE GIBSON, formerly manager of the Uniontown (Pa.) district of the Bell Telephone Company, has been placed in charge of the Washington, Pa., district, succeeding J. H. Clune, who has been made superintendent of the Butler exchange. Ernest Ritter, district manager of the company at Easton, Pa., has been transferred to Allentown in order to keep in closer touch with the plant and traffic department which is located at that place. The Easton office is now under the management of R. D. Frame.

OBITUARY NOTES.

DR. HENRI BECQUEREL died in Paris, France, last month, at the age of fifty-six. Although it is to his pupils, the Curies, that the discovery of radium is due, this discovery was made in carrying out a systematic research to investigate the cause of the invisible rays which Becquerel had found to be emitted by certain compounds of uranium. His announcement that photographic plates enclosed in a light-tight box with uranium salts were acted upon actinically was at first received with a considerable amount of skepticism, but this, on the whole, formed the basis of the field of research which since that time has opened up.

PROFESSOR E. E. N. MASCART died at Paris, France, on Tuesday, August 25, at the age of seventy-one. After graduating from the College of Valenciennes at the age of nineteen, Mascart became a teacher at the Lycées of Lille and Douai. In 1858 he entered the Ecole Normale Superieure, where, after completing his course, he remained until 1864 as assistant on the teaching staff. After filling chairs of physics at Metz and Marseilles he was called in 1868 to Paris to take the position at the College of France of adjunct professor to Renault. On the death of the latter he succeeded to the full professorship. During the Franco-Prussian war he served as assistant director of the cartridge and arms factory at Bayonne. In 1878 he was appointed director of the Central Meteorological Bureau of France, from which position he retired only recently on account of ill-health. In 1878 he published his "Treatise on Static Electricity," in two volumes, and between 1882 and 1886 his work entitled "Lessons in Electricity and Magnetism," which he prepared with Professor Joubert as collaborator, appeared. In 1892 he published his "Treatise on Optics," and in 1900 his "Treatise on Terrestrial Magnetism." During the greater part of his life he was one of the most active figures in the scientific circles of Paris. He was a member of the Academy of Sciences, and served as president of the Physical Society, the International Society of Electricians, the Meteorological Society and the Association for the Advancement of Science. He served also as president of the Committee on Commerce and Manufactures attached to the French Ministry of Commerce and as president of the Commission of Inventions for the Army and Navy. He took a leading part in the several international electrical congresses held in Paris, namely, those of 1881, 1889 and 1900, and was a delegate of the French Government to the International Electrical Congress of Chicago in 1893. He was a Grand Commander of the Legion of Honor.

ELECTRICAL SECURITIES.

The course of the market was generally downward and irregular all last week, some of the declines assuming considerable proportions. A feature of the selling was the aggressive bear pressure and the liquidation of stock which had been held for some time. The adverse factors appear to be the inclination toward a firmer money market, with advance in foreign exchange, and the passing of dividends by several prominent industrials. The government crop report was not considered especially satisfactory, but, on the other hand, a very favorable development was the court decision declaring the commodity clause of the Hepburn act unconstitutional. Developments indicate that the return to industrial activity is to continue comparatively slow. A compilation of railroad earnings for the first six months of this year shows a gross decrease of $235,000,000, while the net loss appears to be about $65,000,000. For the month of August the gross decreased 13.8 per cent, while for July the gross loss was 17.2 per cent, the net decreasing 8.1 per cent.

Dividends have been declared upon the following electrical securities: United Gas Improvement Company; regular quarterly dividend of 2 per cent, payable October 15 to stock of record September 30. Chicago Telephone Company; regular quarterly dividend of 2½ per cent, payable September 30; books close September 26, reopen October 1. Quarterly dividend of 1¾ per cent on the stock of the Manhattan Railway Company, guaranteed by the Interborough Rapid Transit Company, payable October 1 to stock of record September 11. United Traction and Electric Company; regular quarterly dividend of 1¼ per cent, payable October 1. Cumberland Telephone and Telegraph Company; have declared a quarterly dividend of 2 per cent, payable to stock of record September 20; this is an increase of ¼ per cent quarterly, the rate heretofore having been 1¾ per cent quarterly. West End Street Railway Company; regular semiannual dividend of $1.75 on the common stock, payable October 1; books close September 21 and reopen October 2. Portland Railway, Light and Power Company of Oregon; regular quarterly dividend of 1¼ per cent on the preferred stock, payable October 1 to stock of record September 15. Houghton County Street Railway Company; regular semiannual dividend of 3 per cent on the preferred stock, payable October 1 to stock of record September 15. Toronto Railway Company; regular quarterly dividend of 1½ per cent, payable October 1 to stock of record September 15. Union Traction Company, of Indiana; regular semiannual dividend of 2½ per cent on the preferred stock, payable October 1 to stock of record September 25. Western Union Telegraph Company; quarterly dividend of ½ per cent, payable October 15. Halifax Electric Tramway, Limited; quarterly dividend of 1½ per cent, payable October 1. Ridge Avenue Passenger Railway; quarterly dividend of $3 per share; guaranteed by Philadelphia Traction Company, lessee.

NEW INCORPORATIONS.

STAUNTON, VA.—Shenandoah Electric Company. $10,000.

AU SABLE, MICH.—Eastern Michigan Power Company. $10,000.

HARRISBURG, PA.—Portersville Telephone Company, Portersville. $12,000.

SPRINGFIELD, ILL.—Chatsworth Electric Company. To furnish light, heat and power. $25,000. Incorporators: L. A. Walter, J. B. Grotevant, G. W. McCabe, Chatsworth.

INDIANAPOLIS, IND.—Morgantown Light and Power Company, Morgantown. $5,000. Directors: William T. Gibson, Jesse H. Deer, James A. Collett, Joseph H. Enos and William W. Davis.

INDIANAPOLIS, IND.—Public Service Telephone Company, Leesburg. $20,000. Directors: Abraham H. Brown, Frank Bortz, Henry E. Kinsey, John E. Armstrong and Walter H. Stanley.

HARRISBURG, PA.—Carrick & Baldwin Street Railway Company. $6,000. Officers: F. K. Martin, Pittsburg, president; J. C. Bily, F. K. Martin, J. G. Evans, S. T. Tone and W. B. Carson, directors.

COLUMBUS, OHIO—Perry Electric Company, of Crooksville. $10,000. To establish and maintain an electric power plant at Crooksville. Incorporators. J. Edward Horn, J. C. Horn, Charles W. Runk, W. M. Runk and W. W. Hardy.

INDIANAPOLIS, IND.—Logansport, Frankfort & Indianapolis Traction Company. To build an interurban line from Frankfort to Logansport. $25,000. Samuel H. Blakeslee and Allen G. Barone, of Cleveland, and Fred Cook, of Indianapolis.

FAIRMONT, W. VA.—Independent Power and Light Company, of Fairmont. $150,000. To erect electric plants and perform all the functions to which such a plant can be applied. Incorporators: A. H. Donnally, L. C. Wyer, J. R. Linn, J. T. Hill, C. E. Mayers, all of Fairmont.

JOHNSON CITY, TENN.—Unaka Traction Company. To build a street railway from Erwin to Johnson City, through Unaka Springs, to be operated by horse, steam or electric power. $10,000. Incorporators: Isaac Love, W. B. McNabb, A. M. White, F. B. Vines and J. A. Wilson.

CHICAGO, ILL.—Chicago, Wheaton & Western Railway. To tap the region north of Wheaton, Ill., and connect with the Aurora, Elgin & Chicago electric line. $10,000. Incorporators: J. Sidney Condit, J. Percy Strickland, D. W. Peters, R. B. Tabor and H. C. Wood, all of Chicago.

INDIANAPOLIS, IND.—Valparaiso & Northern Railway Company. To construct, maintain and operate street and interurban railroads in Indiana. Its lines will run from Valparaiso, in Porter County, to and in the town of Chesterton. The concern is capitalized at $10,000. Chicago capitalists are named as the incorporators.

WHEELING, W. VA.—Wheeling, Cadiz & Tuscarawas Traction Company, Cadiz. To build a road connecting Bridgeport and Uhrichsville, and passing through Belmont, Jefferson, Harrison and Tuscarawas counties. $10,000. Incorporators: Barclay W. Rowland, Charles L. Scott, Charles F. Branson, William T. Perry, John F. Kennedy and G. W. Grissinger.

EVANSVILLE, IND.—Evansville & Eastern Railway Company, of Evansville. To construct and operate street railway and interurban companies in Indiana and to furnish lighting facilities to Indiana cities and elsewhere. $10,000. Incorporators: John C. Lake, of Lake, Ind.; Marcus S. Sonntag, W. H. McCurdy, Albert F. Karges, William A. Koch and C. H. Battin, of Evansville.

OMAHA, NEB.—Independent Transportation Company, of Council Bluffs. $30,000, consisting of 6,000 shares at a par value of $5. Incorporators: William Leahy, J. R. McPherson, Henry Sperling, J. R. Reed and A. T. Flickinger, of Council Bluffs. To carry on a general transportation business, including the carrying of persons and property in this city and adjacent territory. Officers: William Leahy, president; J. R. McPherson, vice-president; Henry Sperling, secretary; J. R. Reed, treasurer.

TELEPHONE AND TELEGRAPH.

ANAHUAC, TEX.—A telephone line has been constructed between Stowell and Anahuac.

MIDDLETOWN, OHIO—The consolidation of the Bell and the independent telephone companies at West Elkton was effected recently, when the subscribers of the Bell company were transferred to the independent company.

BOSTON, MASS.—The New England Telephone and Telegraph Company has secured control of the Northeastern Telephone Company, the Lewiston-Auburn Telephone Company and the Cumberland Telephone Company, three independents, operating in some twenty-five towns and cities in Maine.

WINSTON-SALEM, N. C.—Manager E. H. Wilson, of the Southern Bell Telephone Company, reports that the company will be in its new quarters by the middle of October. A new switchboard is being installed and the old equipment in the present office in the municipal building will be discarded.

MAUCH CHUNK, PA.—At a meeting of the stockholders of the Carbon Telephone Company, an independent line between Coal Dale and Summit Hill, it was decided to improve the service by extending the line to Tamaqua on the west and Nesquehoning on the east, and connect at both places with the United Telephone and Telegraph Company's lines.

ST. JOSEPH, MO.—The Agency Telephone Company's exchange, including all of the wires, instruments and reserve stock, has been sold to the Clinton County Mutual Telephone Company, of Plattsburg, by Dr. F. C. Owens, of Big Horn, Mont. Three considerations entered into the transaction. The purchaser paid Dr. Owens $1,000, released a debt of $300 due from Owens, and paid to E. W. Miller, of Agency, $4,532.56, secured by a mortgage on the plant. Suit against Dr. Owens for $300 was instituted in circuit court July 16 by the Plattsburg company, which alleged that it had been engaged to repair the Agency lines, and that it had performed services in March, April, May, June and July without recompense. The suit now will be dismissed.

INDUSTRIAL ITEMS.

THE ANDRESEN-EVANS COMPANY, Monadnock Building, Chicago, Ill., has published a handsome catalogue devoted to ore and coal-handling plants and grab buckets.

THE FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., in bulletin No. 1,111, describes and illustrates electric motor drives applied to machine tools. This is a very interesting bulletin and should be in the hands of all those interested in this phase of motor application.

THE MINNEAPOLIS STEEL AND MACHINERY COMPANY, Minneapolis, Minn., announces that the Clarkfield Roller Mills and Electric Light Company, of Clarkfield, Minn., has placed an order for an eighty-horse-power Muenzel producer gas engine and suction gas producer for running its mill and electric light plant.

THE HARVARD ELECTRIC COMPANY, 66 West Van Buren street, Chicago, Ill., announces that although its main factory and stock were seriously damaged by fire on August 28, it is in a position to take care of all orders. The eastern territory will continue to be supplied from the New York city office, and the Chicago factory has recommenced work with sufficient force to fill all orders promptly.

THE COLONIAL SIGN AND INSULATOR COMPANY, Akron, Ohio, has issued an attractive booklet devoted to special porcelain for special purposes. This booklet describes a number of interesting types of fuse-box porcelains, lightning arresters, combination cutouts, pendent signs, condulet covers, attachment plugs, panel terminals, switches, telephone accessories, third-rail insulators, cable supports, strain insulators, gas-mantle products, solid porcelain reflectors, raised sign letters, cutout bases, rosettes and resistance tube.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., has issued an attractive pamphlet giving a brief history of the material used in transformer construction and calling attention to the improved Type H transformer in the manufacture of which the described steel is used. This publication is No. 3,687. Bulletin No. 4,611 is devoted to sewing-machine motors; bulletin No. 4,612 describes the combination ammeter and voltmeter for automobile service, and bulletin No. 4,615 the Thomson direct-current test meter, Type CB-2.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing a circular announcing a ten per cent reduction in the price of Columbia tungsten lamps. Transportation on standard packages of Columbia tungstens will be allowed east of the Mississippi River, and a small additional charge will be made for delivery to other points. The company's record of breakage for six months amounts to approximately two per cent upon the actual value of the lamps shipped. The company is carrying a complete stock of all sizes and styles of Columbia tungsten lamps.

THE MOLONEY ELECTRIC COMPANY, St. Louis, Mo., has published a very handsome catalogue devoted to its high-efficiency transformers. These transformers are made with great care from material of the highest grade procurable. The design of the transformer permits of the most economical distribution of copper, as well as the use of a sufficient cross-section to carry the current with a minimum loss. The all-day efficiencies of these transformers are very high, and some remarkable qualities have been demonstrated after numerous tests covering every characteristic of transformer performance.

THE JENNEY ELECTRIC MANUFACTURING COMPANY, Indianapolis, Ind., it is announced, will break ground in the near future for a factory at Anderson, Ind., which will, when completed, be four times the size of the present establishment in Indianapolis. This company has been in business for many years, and during the last few years has devoted itself largely to the manufacture of electric motors for printing-press operation. When in its new quarters the company will enlarge its present line of alternating and direct-current motors and dynamos, and will become a more conspicuous factor in the manufacture of electrical machinery.

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, Pa., has issued "Hand Book IP," which is a publication of special interest to dealers and contractors. It treats of the application of the "Chloride Accumulator" to small isolated electric lighting and power plants for factories, residences, etc., where electric service from central stations is not available. It shows how the advantages of a twenty-four-hour electric service are made possible by the use of a battery of "Chloride Accumulators," entering fully into the subject and giving illustrations of the types of batteries and switchboards required for installations of different capacities. Specifications and prices for complete installations are given.

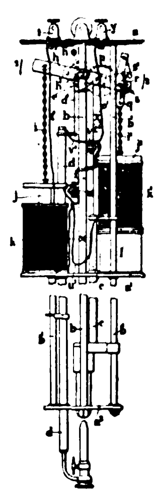
THE STANDARD GAUGE MANUFACTURING COMPANY, Syracuse, N. Y., announces that the Schaeffer & Budenberg Company, of Germany, has sold its plant at Foxboro, Mass., to the Industrial Instrument Company, which was lately organized with Bennett B. Bristol, formerly of the Bristol Company, Waterbury, Ct., as its head. The Standard Gauge Manufacturing Company will operate the plant for the manufacture of gauges, recording instruments, etc., and the property will be deeded to it by the Industrial Instrument Company, as the same interests control both concerns. Watson E. Goodyear, of Naugatuck, Ct., will be president of the Standard Gauge Manufacturing Company; Bennett B. Bristol, treasurer, and Arthur F. Mundy, secretary.

Record of Electrical Patents.

Week of September 8.

897,866. SIGNALING APPARATUS. George F. Atwood, East Orange, N. J., assignor to Western Electric Company, Chicago, Ill. Filed February 26, 1906. The instrument case contains the induction coil, condenser, relays, battery, magneto, switch, springs and ringing system.

897,868. ELECTRIC IGNITION DEVICE OR SPARKING PLUG FOR INTERNAL-COMBUSTION MOTORS. Charles O. Bastian and George Calvert, London, England. Filed June 27, 1906. The ignition device is contained in a removable, renewable glass tube.



897,960.—Electric Arc Lamp.

897,906. LIGHTNING ARRESTER. Frank P. H. Knight, Keokuk, Iowa, assignor to Electric Service Supplies Company, Camden, N. J. Filed June 28, 1907. Separate paths are provided for the circuit-breaker and the discharge. The circuit-breaker is adapted to open the circuit and close the circuit by the normal current.

897,947. LIGHT FIXTURE. Arthur B. Wilson, St. Louis, Mo., assignor of one-half to George T. Breen, St. Louis, Mo. Filed September 27, 1907. The hollow body is adapted to receive hollow lamp-supporting arms, and is fitted with a flanged brace ring.

897,950. SYSTEM OF ELECTRICAL DISTRIBUTION. Joseph L. Woodbridge, Philadelphia, Pa. Filed January 20, 1908. A rotary converter is connected between the alternating-current circuit and the transforming apparatus, and means are provided for responding to changes of electrical condition in the alternating-current circuit.

897,960. ELECTRIC ARC LAMP. Pierre M. Capitaine, Les Lilas, France. Filed November 11, 1907. Means are provided for varying the adjustment of both carbon-holders by means of series and shunt magnets.

897,965. SYSTEM FOR TRANSMITTING ELECTRIC CURRENTS TO CARS. John J. Eagan, San Francisco, Cal. Filed October 18, 1905. The train is electrically connected by means of mutually engaging rods curving downwardly at their ends to contact with side arms.

898,030. SYSTEM OF REGULATION. Joseph Bijur, New York, N. Y., assignor to the General Storage Battery Company, New York. Filed April 4, 1906. A storage battery is used for compensating variations in the working circuit.

898,052. ELECTRIC ARC LAMP. Robert E. Leve, New York, N. Y. Filed January 22, 1908. The winding drum, brake-shoe and escapement wheel are mounted concentrically upon a single rotatable shaft.

898,055. ELECTRIC BATTERY. William MacMillan, New York, N. Y., assignor of one-half to Egbert Winkler and one-half to John J. Walsh, New York, N. Y. Filed August 18, 1902. The battery comprises a plurality of concentric elements located within a cloth-lined insulating exterior cylinder.

898,058. MEANS FOR REGULATING DYNAMOELECTRIC MACHINES. Wilbur L. Merrill, Schenectady, N. Y., assignor to General Electric Company. Filed February 20, 1906. Means are provided to modify the voltage of the generator of the motor-generator set so as to maintain the speed of the motor constant independent of its load.

898,061. FUSE BOX. Harry P. Moore, Newburyport, Mass., assignor to Chase-Shawmut Company, Boston, Mass. Filed April 8, 1907. The terminals are out of line with the fuse support.

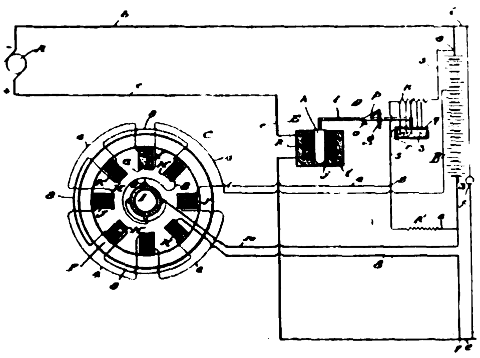
898,073. APPARATUS FOR SPEECH TRANSMISSION. Herbert E. Shreeve, Wyoming, N. J., assignor to American Telephone and Telegraph Company. Filed October 15, 1907. Means are provided for varying the magnetic flux traversing the induction coil.

898,083. ELECTRIC LIGHT FIXTURE. William Amstalden, Amador City, Cal., assignor of one-half to Aaron Weil, Amador City, Cal. Filed December 31, 1907. The lamp cord is contained in a casing provided with a spring-controlled winding drum.

898,086. MULTIPLE ELECTRIC FUSE CUT-OUT. Wilhelm Boehm, Berlin-Charlottenburg, Germany. Filed June 8, 1907. A fuse comprising a plurality of independent sections is contained in an annular chamber and fed as may be necessary through a fuse-containing passageway.

898,095. SIGNAL BOX. Frederick W. Cole, Newton, Mass., assignor to the Gamewell Fire-Alarm Telegraph Company, New York, N. Y. Filed June 10, 1906. Means are provided for the transmission of selected different signals.

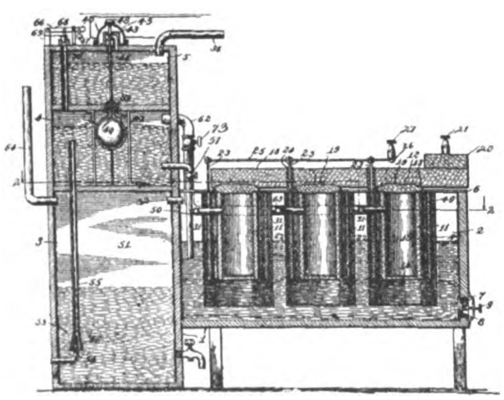
898,097. TERMINAL FOR ELECTRIC CABLES. Charles W. Davis, Edgeworth, Pa., assignor to Standard Underground Cable Company, Pittsburg, Pa. Filed December 23, 1907. A combination multiple petticoat insulator having a conducting core and means for insulating a plurality of separate conductors.



898,030.—System of Regulation.

898,104. CIRCUIT-CLOSER FOR CALL BELLS. Robert Henderson, U. S. Navy. Filed June 4, 1906. The weighted knob or handle contains a helical spring adapted to effect the closure of a circuit upon any increase of pressure.

898,133. APPARATUS FOR PRODUCING VOLTAIC HIGH-CURRENT ARCS. Harry Pauling, Gelsenkirchen, Germany, assignor to the firm of Salpetersäure-Industrie-Gesellschaft, G. M. B. H., Gelsenkirchen, Germany. Filed July 29, 1907. The arc is formed between a pair of curved electrodes, and means are provided for spreading out the arc in a strong magnetic field.



898,055.—Electric Battery.

898,189. ELECTRODEPOSITION OF ALLOYS. Sherard O. Cowper-Coles, London, England. Filed August 2, 1907. The method consists in employing an anode of the alloy to be deposited, and an anode of each of the metals composing the alloy, and independently varying the current passing through the anodes of the metals of the alloy as desired.

898,195. SUPERVISORY SYSTEM FOR TELEPHONE LINES. William W. Dean, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed October 31, 1903. Means are provided in connection with a supervisory relay to deprive the signal system of operating current.

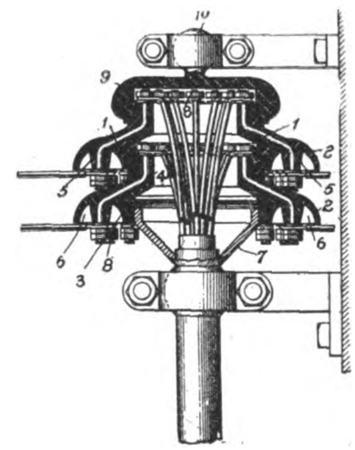
898,197. WIRELESS TELEGRAPH APPARATUS. Halsey Dunwoody, U. S. Army. Filed May 21, 1907. A portable, self-contained radioelectric circuit.

898,216. ELECTRIC RAILWAY CONDUIT. Elmer E. Granger, Chicago, Ill. Filed August 4, 1906. A flexible strip or connector in the conduit is capable of an undulatory movement throughout its length under the influence of polar magnets carried upon the car.

898,218. ELECTRICAL PIANO-PLAYING INSTRUMENT. Alvan L. Hart, Burlington, Iowa. Filed November 29, 1902. The armature operates directly upon its magnets and transmits motion to the hammer.

898,219. RAILWAY ELECTRIC SIGNALING. Job Hutchinson, New York, N. Y. Filed May 10, 1905. This signal is biased to danger, and is normally electromagnetically restrained when its section is unoccupied by a car or train.

898,220. CONTACT RAIL FOR ELECTRIC RAILWAYS. Job Hutchinson, New York, N. Y. Filed May 10, 1905. The rail proper and its flexible cover both afford metal contact with the contact shoe.



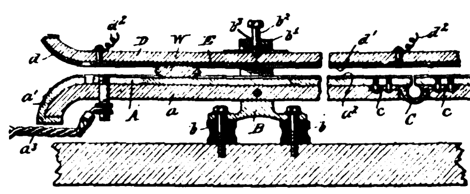
898,097.—Terminal for Electric Cables.

898,221. RAILWAY ELECTRIC SIGNALING SYSTEM. Job Hutchinson, New York, N. Y. Filed January 2, 1906. Means are provided for controlling the signals when the section is occupied by a car.

898,283. TELEGRAPHONE. Harve R. Stuart, Wheeling, W. Va. Filed September 24, 1907. Means are provided for making the telegraphone instrument unresponsive.

898,296. SYSTEM FOR CONTROLLING TRAINS. Paul Winsor, Weston, Mass., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed August 12, 1905. A double-circuit, relay-control block-section signal system.

898,313. ELECTRIC RECORDER FOR ICE PLANTS. William D. Cain and Wade H. Williams, Durant, Okla. Filed May 9, 1908. A detent closes the circuit upon the passage of a block of ice, and causes an index to be made on a dial system.



898,220.—Contact Rail for Electric Railways.

898,324. ELECTRIC SIGNALING SYSTEM. Elmer R. Coe, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed May 11, 1908. The track rails are provided with a signaling current from a high-potential system with a transformer interpolated.

898,370. HIGH-TENSION MAGNETO. Edward B. Jacobson, Pittsfield, Mass., assignor to Pittsfield Spark Coil Company, Pittsfield, Mass. Filed January 16, 1907. The potential is built up by inductive windings and compound field magnets, with a condenser in the primary.

898,404. PROCESS OF MAKING ARTICLES BY ELECTROPLATING. Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to Edison Storage Battery Company, West Orange, N. J. A coating of copper is electroplated on a former, a film of nickel electroplated on the copper coating, and a film of iron electroplated on the nickel film.

CONTENTS

THE EVOLUTION OF THE LAWS OF THERMODYNAMICS.

For his presidential address before the engineering section of the British Association for the Advancement of Science, which held forth recently in Dublin, Ireland, Mr. Dugald Clerk took the subject of the discovery and evolution of the laws of thermodynamics. The address is entirely historical in nature, but there runs all through it a philosophical interlude which adds to the recapitulation the charm of easy reading and affords a most satisfactory method of reviewing our knowledge of a subject dear to the heart and mind of all engineers. The story is romantic, too, and we can live over some of the struggles and gratifications which came to those sturdy workers who have done so much to place our scientific knowledge on a firm footing.

It seems almost absurd, however, in the light of our present knowledge and our superficial scanning of text-book information, that these discoveries were made only at such an expenditure of mental and physical effort. Notwithstanding the fact that steam-engine development had reached a very satisfactory stage, it was not until 1849 that Carnot evolved his famous theory of the functions of a perfect heat medium; and, even at that time, Carnot was very much in the wrong in not a few of his assumptions. With Dugald Clerk we go over the ponderings of Joule and Thomson, and we can see the latter, a young man of mighty intellect, becoming impressed with Joule's announcement and calling to the attention of those who very coolly received these statements their importance and the great field of opportunity that they opened up. We can almost realize a psychological emotion at the joining together of these two intellectual forces, and we can only wonder, in the light of the subsequent achievements of these great minds, that they did not arrive earlier at their splendid conclusions. And, reading further, we are struck with amazement at the tenacity with which other brilliant minds clung to opinions which were finally overcome and rendered obsolete by later investigations and discoveries.

This brings to mind at the present day the thought of the work which is now engaging the attention of some of our greatest intellects in the fields of wireless communication and the various phenomena connected with the study of radioactive forces. Surely it seems that the study of these forces requires a knowledge and an intellect and an ability for abstract reasoning the like of which did not exist in the problems connected with the laws of thermodynamics. Will culture have advanced to such an extent fifty years hence that students, poring over their text-books, will wonder why Becquerel and Hertz, the Curies and Kelvin, Fessenden and Stone, Roos and Pickard, Marconi and De Forest, did not arrive at definite conclusions concerning the phenomena with which they were dealing with less expenditure of effort? Will it then seem that these things should have been more readily understood, or are we becoming bankrupt of intellectual and scientific resources, as was pointed out a decade ago—before Hertz and others of his scientific stature enunciated their wonderful theories concerning the ion and the atom of electricity?

When we realize the marvelous accumulation of information with which we have garnished our intellectual storehouses and read the history of this advance, we are impressed with the fact that for each problem there has been developed a mind sufficiently great to solve it, and we must feel that, even though at times the riddle of the universe seems imponderable, we shall still ascend peak after peak of learning and some day arrive, not at the stars, but sufficiently near to realize that they and we are made of the same clay.

A NEW DEPARTURE IN ILLUMINATING ENGINEERING.

Within the last few years many central stations have realized that a field exists for the better use of illumination on the premises of certain customers, and in an informal way some of the more progressive companies have from time to time gone out of their way to offer suggestions leading to improvement. The most notable step in this direction that has thus far been taken is the action of the Boston Edison Company in opening a special department of illuminating engineering on September 1 at its main offices. This new branch of the company's work will afford free consultation on the application of electricity to lighting problems for any of its customers who will take the trouble to call upon or send for the expert advice which is now at their disposal. The company believes that in helping its customers to use electricity most efficiently it is creating a satisfied clientele which is a most valuable asset, and while in many cases the recommendations of the department will mean a reduction in the monthly bills of customers applying for advice, the fact that the prosperity of the company is intimately related to the prosperity of its clients will in the long run work out to the general advantage of all concerned.

For any public-service corporation to voluntarily take steps which may reduce a portion of its immediate income requires a broad and courageous view of the business situation, and not a little faith in the intelligent appreciation of its customers of efforts to serve them well. In the last twenty-two years the average cost of electricity to Boston Edison customers has been reduced seventy-five per cent. The average dwelling and office cost has been cut fifty-eight per cent; stores, eighty-three per cent, and long-hour burners, eighty-seven per cent. Within the last two years the average cost has been reduced forty per cent. The company has taken from the first an advanced and progressive position regarding the tungsten lamp and other high-efficiency units, and in starting the new department it is expected that the immediate effect of the recommendations will be to create general satisfaction with the policy of showing customers how to get the most and the best light for their money. The numerous inquiries immediately received after the opening of the department was announced show conclusively that the Edison company's customers in Boston and its vicinity are thoroughly alive to the merits of a proposition of this character, and it is expected that some remarkably interesting data will be accumulated within the next few months. We do not know whether the company formally intends to handle the power business in a similar way, but if the work of the illuminating division should be of a permanent character, it would be a logical step to carry the same idea into the motor field. To a large extent, of course, all progressive companies are glad to advise their customers as to the use of power, but the handling of such problems by a special branch of the central station organization affords a more systematic method of dealing with these semi-technical questions.

That there is room for a great deal of improvement in both electric lighting and power applications can not be doubted by any one whose opportunities for observation cover a large part of this country. One of the reasons for this condition is the lack of the proper advice when the original installation is made, and another is the inadequate handling of the statistical end of the power and lighting problem by some of the central station organizations. All new and revised electrical installations call for more or less real engineering skill, and in many instances the purchaser has been entirely unwilling to pay for the advice of an experienced engineer in selecting his apparatus and its method of application to his peculiar conditions. The result has been that while many electric power installations are more efficient than the steam or other mechanical transmissions that preceded them, the bills are actually higher than would be the case if a skilled engineer had been given the chance in the first place to carefully study the conditions. Again, central stations are notoriously deficient in the filing of complete data of their power and lighting installations, so that when the commercial departments undertake to secure new business, many problems have to be figured without the advantage of referring quickly to the detailed facts. The costs of the installation may be filed with some care, but the particulars of the mechanical drive, speed ranges, normal and overload capacities are apt to be lacking. In the lighting field the same paucity of accurate data is notable. A company may have a complete list of all the mercantile houses, for instance, which have adopted the tungsten lamp in place of the gas arc, but it will be unusual if its files contain any particulars of the installation in the line of room sizes, wall colors and height of installed lamps above the floor. It is not enough to tabulate the number of lamps replaced in each case. In a recent trip through about a dozen states in search of central station power data, only one company was found which had the details of the pulley sizes in its possession, in connection with its applications of motor driving.

These conditions will inevitably be remedied if the central stations find it profitable to take up and continue the advising of their customers along the lines started in Boston, and in cases where an outside engineer would clearly never be called in there is no doubt that much good may be expected from such a policy. Experience alone will tell just where the central station should cease to advise its customers and where the consulting engineer should step in. Presumably the time is scarcely ripe as yet for highly successful independent practice in the minor problems of illuminating engineering, and in the smaller power applications the cost of expert consulting advice from other sources than the central station or manufacturer's staff is clearly prohibitive. In a general way it would seem that when the work is of sufficient magnitude to require the making of plans and specifications by an outside party, the central station should stand aside, furnishing its advice freely as before, but refraining from entering distinctly upon the consulting field through the preparation of costly drawings, the writing of specifications and the supervision of construction. There is clearly a limit to the wise expenditures of a central station for advising its customers, but time alone will show where this limit falls.

DESTRUCTION OF THE PARIS CENTRAL TELEPHONE EXCHANGE.

Despatches from Paris state that on September 20 a disastrous fire destroyed the central telephone building and a portion of the post-office at the French capital. It is estimated that the loss will approximate $6,000,000. This is, however, the estimate for only the material loss, as no approximation can be made of the loss incident to the prostration of business and the anxiety and mishaps which ensued from the tying-up for even a short time of the arteries of communication of a great cosmopolitan centre. Not only was telephonic communication suspended, but the outbound telegraph systems were also put temporarily out of commission. Heroic work under the direction of the under secretary of posts and telegraphs soon re-established telephonic communication with London and Brussels from the Bourse and the post-office. Arrangements are being made to set up a provisional exchange to take care of commercial communication.

For a long time the telephonic situation in Paris has been anything but satisfactory. Only recently we had occasion to review an article by the president of the Paris association for the improvement of the telephone service, in which it was emphatically deplored that the government was entirely incompetent to cope with the necessities of the situation, and advocating the turning over of the system to a private concern. Many leading business men of Paris hold the opinion that it is only by enlisting private capital in the enterprise that the vast amount of money needed to rehabilitate the system can be procured, as the government appropriation is entirely too small, and the inertia of the government organization will not allow the present generation of business men in Paris to secure the advantages of a modern system. It is deplorable indeed that Paris is thus so suddenly deprived of its telephonic communication, because, bad as the service may have been, it certainly was a great improvement over no service at all. Now, however, that an accident has made it necessary for actual and material rehabilitation, it would be well for the government to give ear to the protests of those who need and use the telephone, and encourage the installation of a modern system built and operated, if need be, entirely by private capital.

COMMERCIALISM.

The convention of the Vermont Electrical Association, held at Bennington last week, was devoted mainly to a discussion of the commercial side of public utility work, the technical, or engineering, features of central station service being referred to only incidentally. The keynote of the situation was sounded in the presidential address, when it was declared that the technical problems had been pretty well solved, and that there was nothing essentially new to be discussed at the present time. Matters of public policy, of increasing the number of new customers and retaining those already on the books of the company, were to-day of prime importance to the central station manager. One of the speakers, a copious abstract of whose remarks appears on another page, made the bold statement that five years hence the engineering features would be incidental to what will then be regarded as a purely commercial proposition of manufacturing and selling a necessary commodity. Mr. Rae's remarks in some directions are radical, and the sting will go deep and possibly hurt a good deal; but they should not be taken so much as an attempt to teach one one's business as they should be regarded as the effort of the specialist to indicate possible lines along which special work may be conducted. The men who are to-day foremost in developing plans for increasing the sale of current are not claiming to know much, if anything, about the engineering features of central station work, but they do believe that they know how to sell a product once it is available for the market.

Now, we must realize that there is plenty of opportunity for each to help the other. The engineer will devote his attention to making his station safe, his transmission system reliable, and to producing electricity at the lowest possible cost consistent with reliability. On the other hand, the executive department will unceasingly direct its efforts toward increasing the market for its product by, first of all, insisting that the public shall know that it is in business the same as any other manufacturer, that its product is tangible and is subject to the same laws as any other manufactured product, and, while encouraging a monopoly of this service, indicate the same regard for its patrons as exists when there is the most open-handed and free-for-all competition.

Vermont Electrical Association.

Seventh Annual Convention, Held at Bennington, Vt., September 16 and 17.

THE seventh annual convention of the Vermont Electrical Association, held in Bennington, Vt., September 16 and 17, was unique in several respects. There were only three numbers on the programme, and all of these were purely commercial. The fact is significant. "We feel that the technical problems are pretty well solved and not especially new," said President E. E. Larrabee in opening the meetings, "but the commercial questions are always new and we never tire of talking of how to get more new business without losing any of the old, how to create demands for current-consuming devices and how to make the use of electricity a necessity instead of a luxury."

The programme as announced was made up of papers by H. C. Rice, of Cleveland, Ohio, on "The Tungsten Lamp and Its Effect Upon the Smaller Central Station"; by Frank B. Rae, Jr., and George Williams, of New York, on "Commercialism"; by Henry L. Doherty, of New York, on "Public Service Corporations." Owing to a misunderstanding Mr. Doherty was unable to be present, but the association was fortunate in filling his place with an address on "State and National Electric Light Associations," by T. Commerford Martin, of New York. Glenn Marston, of New York, also spoke on "Public Policy."

About 100 members and guests were present in the meeting room when President Larrabee called the convention to order.

Harry C. Rice followed with his paper on tungsten lamps, which combined a brief sketch of the technicalities of lamp making with much practical advice on the commercial aspects of high-efficiency units. In describing tungsten lamps, Mr. Rice showed specimens of the ore from which the metal tungsten is reduced, together with samples of crude and refined tungstic oxid, pure tungsten in powdered form and finished filaments. He then launched into the commercial questions involved in the selling and renewing of these lamps, covering the subject at length.

Comparisons were made between the tungsten lamp and the flaming arc, gas arc, gas burner, Nernst lamp and various incandescent units, and arguments adduced to prove that there is no reason to fear the tungsten; rather that central station men should take the initiative and offer the new lamps rather than wait until they are driven into this field of lighting.

In the discussion that followed many valuable points were brought out. H. W. Brown, of the General Electric Company, pointed out the difficulties and percentage of loss in manufacture and stated that as the lamps come into more general use the price will gradually decrease. Their present high cost, he said, precluded free renewals, but this was really an advantage as it served to educate the public away from the free renewal and made them appreciate the economy of high-efficiency units. Mr. Brown also talked at some length on the monthly rental plan which is being tried in various localities. At Lowell, Mass., a flat rate of twenty-five cents per lamp per month is charged for tungsten renewals; at Elkhart, Ind., the rate is twenty-four cents for a forty-watt lamp, twenty-seven cents for a sixty-watt lamp and thirty cents for a 100-watt lamp. The plan, he said, was proving successful.

Samples of the twenty-five-watt tungsten lamp were exhibited and led to considerable discussion as to their effect. The feeling was expressed by several of those present that both this and the 250-watt size can hardly be considered as commercially available, though numbers have been installed in practical service with satisfactory results. The city of Hartford, Ct., Mr. Brown said, is about to install 250-watt tungstens for street lighting in order to secure data on results. Mr. Larrabee stated that where a plant is loaded to its capacity, the tungsten lamp offers a means of saving investment in new generators and enables the lighting man to secure the same income from customers with longer hours of burning.

The discussion of Mr. Rice's paper occupied the entire afternoon session.

The evening session was held in the rooms of the Bennington Club and was attended by a number of the leading business and professional men of the city. The first item on the programme was Mr. Rae's paper on "Commercialism," in part as follows:

Five years ago commercial engineering in the central station field was the doubtful side line of a technical business. Five years hence electrical engineering will be only incidental to what will then be an almost purely commercial enterprise.

Five years ago, also, the lighting company was—in the public mind—a monopoly, a slimy serpent of graft and grab, proceeding by devious and subterranean ways, debauching city officials, pre-empting public lands and franchises and robbing the widow and orphan. Five years hence it will be recognized generally that the central station is nothing more or less than a manufacturer and retailer of a necessary commodity.

The reason for these changes may be summed up in one word—commercialism.

DEFINITION.

Central station commercialism is even yet vaguely understood. To many managers of lighting plants it means little more than a spasm of hysterical advertising. To others it means such advertising plus a season of brazen solicitation by underpaid canvassers. But to a few, perhaps one per cent of the central station managers of the country, it means the wise conduct of business along business lines, unhampered on the one side by too narrow engineering ethics or upon the other by political intrigue or financial jugglery.

It embraces—I name them in the order of their importance—public policy, general management, soliciting, advertising.

Let me define these briefly.

PUBLIC POLICY.

Public policy means the company's attitude and policy toward the public. One point may well be remembered, however: public policy is not something to resolve about in board meetings and spread upon the records; it is the mainspring of daily routine. It applies not only to public officials, newspapers and important customers, but to the ignorant foreigner who kicks about his minimum bill. It applies whether you have indigestion or not; it must be maintained unchanged in the face of any accident to plant or lines; it must be followed by every man in the organization every hour of the day.

GENERAL MANAGEMENT.

General management means what it says—general management. It is part of commercialism—the most important part.

The organization of a central station personnel parallels closely the layout of the plant and system. The board of directors is the prime mover. The general manager is the generator; the engineers, linemen, office force and solicitors are the apparatus energized, all doing a variety of work over a large or small territory.

but all getting their impetus from one source. And just as the generator in your plant does not actually perform the work of the motors on the lines, so the real general manager does not do the work of his employés. It is commendable to be able to strap on a pair of climbers, shin up a pole and demonstrate to some mutton-headed lineman the right way to do his work—but it is poor management. A good manager would not have that kind of a lineman.

This holds in all departments. The manager draws his pay for managing, not for being every employé's superior in every branch of central station work. Successful management requires a certain amount of physical and mental leisure in which to ponder and plan. The man who clutters his brain with the detail of non-essentials will be unable to give clear-sighted, unhurried consideration to those larger problems which daily confront him. Of these problems nine out of ten are commercial.

THE COMMERCIAL CAMPAIGN.

First of these problems is the main plan of the commercial campaign; there must be one, whether or not a company employs solicitors and advertises. Just as one would not build a power-house without first sketching it out on paper, so there can be no commercial success without some sort of prearrangement. Without it you would only putter.

Right here too many managers err. They confound a business-getting scheme with a commercial plan. They hit upon some such detail as the installing of signs on flat rates or of loaning tungsten fixtures and renewing the lamps for a set sum per month. Those are schemes, not plans.

A commercial plan is a broad policy of commercial advancement based upon the daily load-curve, the condition of the company treasury, the status of the company's securities, local business and political conditions and the manager's ability as an organizer and executive. Such a plan has its foundation on the bed rock and its purpose is a commercial structure which shall endure indefinitely. (And here let me say parenthetically that makeshifts are the curse of America, and the manager who knowingly is content with a makeshift commercial plan writes himself down as a sloven or a fool. Happily, most such mistakes are the result of shortened perspective.)

The petty detail of the day is so close to the eye and looms so large that one can scarcely see it in its true relationship to the larger scheme of things. Like the boy in the fable, there are so many trees we can not see the forest. But if we recognize the difficulty its correction is easy.

Having sketched your main commercial plan—one that is broad, solidly grounded, yet flexible enough to allow for technical, political or business developments—it will be found that the various business-getting schemes, devices and methods will take their proper places. There is an abundance of such schemes, all good when adapted to local conditions. Their danger lies in the tendency to *adopt* rather than to *adapt*. No two sets of local conditions are identical, and no two central station organizations are the same. The electrical fraternity is fortunate in that it is common practice to interchange ideas and experiences, but when this intercourse results in the method of one manager being copied exactly and slavishly by another, without regard to the dozens of peculiar conditions surrounding each, it is a decided disadvantage. Do not think from this that I advocate nothing but new and original schemes. The company that relies wholly upon the brains within its organization will have a hard time. Gather ideas where you will—from the trade press, the manufacturer's salesman, the experience of other industries, from your fellow managers—take them where you find them, but make them your own. Fit them to your needs—adapt them to your organization—trim and cut or expand and enlarge them to meet your local conditions.

SOLICITING.

When it comes to the actual soliciting of a contract, adapt again your scheme to the specific case in hand. Make it fit not only your own requirements, organization and local conditions, but the particular needs and individual characteristics of the man whom you solicit. This is important. Too many companies adopt an idea and then try to force it, willy-nilly, down the throats of their clients. It is a vain and saddening experience. Despite your best arguments to the contrary, the average business man will persist in believing that he knows something about his own affairs. Nine men in ten will rebel at the cut-and-dry scheme, the standard and uniform "free sign," the ready-to-wear window lighting or store equipment. By all means have a general scheme, but make it flexible; allow for the idiosyncrasy (or idiocy, if you prefer) of the individual customer.

And give your solicitors a chance to use that flexibility. At the risk of being guilty of bragging, I may say that I sell sixty per cent of the men I call on. This is not the result of crafty salesmanship or superior intellect. It is because I never see a man with a sales proposition that has not been carefully adjusted to fit his needs and give him results. All his objections are provided for and refuted in advance. Not only that; the made-to-measure proposition is something which he can and will endorse immediately, enthuse over and insist upon with the least possible delay. The central station salesman can do the same. He knows—or should know—every customer in advance. He knows that man's business, rating, character, possibilities, prejudices. What easier, then, than to fit the scheme to the man, instead of trying to stretch or compress every man to a stock scheme?

A trouble experienced by too many lighting companies is that they get results from only a very small percentage of their salesmen's calls. This is not always the salesman's fault; generally it is because they either insist upon too many calls or seem to the salesman to demand too great immediate results. And the salesman, hurrying from door to door like a book agent the last week before Christmas, neither prepares his way in advance nor leaves a friendly opening for a call back.

In guiding salesmen, give them a little head, counsel them to patience and careful preparation, rehearse with them the day's campaign. Then, when a critical moment comes, swing every ounce of weight, every breath of influence, to the aid of the man with the order book. And when he has won, be free with the praise that heartens him for the next conquest. The great mistake in this field consists in dubbing our salesmen "solicitors" and in looking upon them as a species of business-getter but one removed from the book agent—poorly paid, delegated with no authority, supported only when convenient. If you hire salesmen, hire good ones. Give them your confidence and support. Treat them like men. Cultivate and permit them to use their brains, tact, discretion. It pays.

ADVERTISING.

Advertising, as it is generally understood, has at best but a minor place in the central station commercial plan. The most effective printed advertising in the world will only carry a short way. It is simply a manifestation of the company's public policy and to be effective must be reinforced by fair, liberal and tactful management, and followed up by clean, businesslike and earnest solicitation.

But if we take the better and broader

meaning of the word, advertising is of next importance to management. As now understood by the most thorough advertising men, the word embraces whatsoever influences the public mind as related to the company. Thus, the neat appearance of your office boy is good advertising. A sweet-voiced, tactful telephone operator; a well-dusted window display; an attentive receiving teller; a good-natured, likable meter-reader; a well-timed contribution to charity; a good cigar and a warm handclasp offered in unison with sincerity to a newspaper man; quick, courteous attention to complaints; prompt apology for errors; earnest endeavor to serve any one anywhere at any time in matters electric —these are forms of advertising, and the best advertising. They cost nothing. They mark the successful manager. They are so intangible that one notes only their absence; their presence I have known to ward off municipal ownership and double dividends.

A certain amount of printed advertising is of course necessary and profitable, but it must be prepared with skill and care. If you have not the skill or lack time to bestow the care, hire it done. It is of the same importance and should have the same particular attention which your lawyer gives to a franchise or a contract. As a matter of fact, an advertisement is a contract and in some states can be enforced in court of law.

The most successful printed advertising for a central station is that which reflects most broadly to the advantage of the city. Be an enthusiast for the town. Find the opportunities for bragging, and whoop it up. Next in importance is educational advertising—the A B C's of electricity presented in words of one syllable. Such advertising lightens the work of your solicitor and brings voluntary inquiries for exact figures. Finally, there is the general publicity—interviews, personals, news of the company, write-ups of notable installations which gratify the merchant, stories of the wonders of electricity which make folk appreciate your service. These are all advertising, all easy to secure, all profitable when published.

Mr. Rae was followed by George Williams, who exhibited a large number of lantern slides showing interesting and spectacular examples of street, sign and outline lighting. Mr. Williams's remarks were brief comments on the installations shown, but he took pains to point out that the brilliant illumination of business streets serves the city as the best possible municipal advertising and greatly increases all local business. The policy of the lighting company, he said, should be to do whatever it can for the city in which it operates; to arouse public spirit, institute and encourage movements toward municipal betterments and make the people realize what a great and important part electricity plays in their prosperity. The views and remarks of Mr. Williams were received with enthusiasm, not only by members of the association, but by the business men present.

Glenn Marston was then introduced and gave a short talk on "Public Policy," saying, in part, "No farsighted public utilities man objects to reasonable state regulation; it is the unreasonable and municipal regulation that harms. Nor do we object to municipal ownership as such, but to the false showings made by municipally owned plants which make the public believe that such plants operate more cheaply than those owned by individuals or corporations." He then stated that reasonable control, which should include municipal with private plants, would show that business men can conduct their business better than politicians can conduct similar business for a city and, if the truth were known, no city would ever want municipal ownership. In dealing with the work of public utilities commissions, Mr. Marston pointed out that they were as beneficial to the small company as to the large and said unreservedly that no public service law, honestly drawn for the mutual protection of public and company, but would prove of immense benefit to the lighting industry.

T. Commerford Martin made an able address on the purposes of associations and the advantage of joining with the National Electric Light Association. After sketching briefly the history of the industry and quoting figures to show its huge importance to-day, Mr. Martin said that the future lies wholly with the central station managers. Touching the subject of state control, he pointed out that the public service commission is not a menace but a dam which will, in future, hold back any tide of socialism or worse evil which may arise, and predicted that within ten years every state in the Union will have such a commission. Mr. Martin's words in praise of the work done by utilities commissions in New York, Massachusetts and Wisconsin created a profound impression.

The purpose of Mr. Martin's address, however, was to urge the Vermont Electrical Association to co-operate with the national association, and in this he was successful.

The executive session was held just prior to the regular meeting on Wednesday afternoon. The question of co-operating with the state legislature in drafting a fair and equitable public-utilities bill was discussed at some length and steps taken toward this end. The matter of closer relationship with the National Electric Light Association was also favorably considered. The following officers were elected:

President, F. H. Parker, Burlington Light and Power Company, Burlington.

First vice-president, James E. Davidson, Consolidated Lighting Company, Montpelier.

Second vice-president, C. E. Parker, Vergennes.

Secretary-treasurer, A. B. Marsden, Manchester.

Members of executive committee: Three years, C. C. Wells, Middlebury, and George S. Haley, Rutland.

On Wednesday evening President Larrabee gave an informal dinner at the Bennington Club in honor of F. H. Parker, the incoming president of the association. The guests were:

F. H. Parker, Burlington, president-elect Vermont Electrical Association.

Hon. F. E. Howe, Bennington, representative to legislature and publisher of the Bennington *Banner*.

Hon. C. H. Dailey, Bennington, collector of customs.

I. E. Gibson, Bennington, president Bennington Club.

O. M. Barber, Bennington, attorney.

Colonel F. S. Richardson, Bennington.

A. B. Marsden, Manchester, secretary-elect Vermont Electrical Association.

George S. Haley, Rutland.

T. C. Martin, New York, editor *Electrical World*.

Harry C. Rice, Cleveland, vice-president G. I. Lamp Company.

George Williams, New York, Henry L. Doherty & Company.

Glenn Marston, New York.

Frank B. Rae, Jr., New York, editor *Selling Electricity*.

The clambake on Thursday was particularly enjoyable. The members of the association and their guests left the headquarters in the Putnam House at about 10.30 for the picnic grounds and amused themselves with various sports until the bake, which was ready shortly after one. The bake was pronounced "the best ever."

E. D. Strickland came down from Buffalo to direct a rejuvenation of the Sons of Jove. The ceremony was performed with much pomp and circumstance—and now nearly everybody in Vermont is a Jovian.

The Association of Edison Illuminating Companies.

The annual convention of the Association of Edison Illuminating Companies was held at the Hotel Aspinwall, Lenox, Mass., September 15, 16 and 17. The convention was called to order on Tuesday morning, September 15, at 9.30 o'clock, and the presidential address delivered by Alex Dow, of Detroit, Mich. The report of the executive committee was presented by W. W. Freeman, Brooklyn, N. Y., secretary, and the report of the treasurer by Louis A. Ferguson, of Chicago. J. W. Cowles, of Boston, presented the report of the Committee on Meters. A paper entitled "Measurements with Portable Testing Instruments" was read by F. P. Cox, of Lynn, Mass. The report of the Committee on Electric Heating was presented by John F. Gilchrist, chairman. This was followed by a paper entitled "A Study of Residence Lighting." The report of the Committee on Storage Batteries was presented by Louis A. Ferguson, Chicago, chairman, followed by a paper by P. S. Millar, of New York, entitled "A Review of the Policies Pursued by Edison Companies in Handling Incandescent Lamps." The report of the Committee on National Code was presented by William C. L. Eglin, Philadelphia, chairman.

The second session was held on Tuesday evening. The report of the Committee on Incandescent Lamps was presented by John W. Lieb, Jr., New York, chairman. John W. Howell, of the incandescent lamp department of the General Electric Company, Harrison, N. J., delivered a talk on "Recent Developments in Metal-Filament Lamps." A paper entitled "Probable Effects of the Higher-Efficiency Lamp on Central Station Income" was read by E. F. Tweedy, New York. A paper entitled "A Self-Supporting Tungsten Lamp Campaign" was read by M. S. Seelman, Jr., of Brooklyn.

The third session was held on Wednesday morning, when the report of the Committee on Steam Turbines was read by Charles N. Parker, Boston, chairman. A paper entitled "Operation of the Boiler Plant and Cost of Making Steam" was read by J. P. Sparrow, New York. A paper entitled "Supplementary to 1907 Paper, 'Steam Heating from Central Stations,'" was read by B. R. Fales, Detroit. A paper entitled "Modern Substation Apparatus" was read by E. M. Allen, Schenectady. A paper entitled "Single *Versus* Three-Phase Transformers for Distribution Purposes" was read by L. L. Elden, Boston. A paper entitled "Short-Circuits on Alternators" was read by E. J. Berg.

The fourth session was held on Wednesday evening. The report of the Committee on High-Potential Disturbances was presented by W. F. Wells, Brooklyn, chairman. Dr. Charles P. Steinmetz delivered a lecture entitled "Electrical Engineering Problems of the Future."

The fifth session was held on Thursday morning. The first paper was entitled "Some Advertising Notes, with Particular Reference to the Advertising Value of the Display Room," by Howard K. Mohr, Philadelphia. A paper entitled "The Status of the Special Customer" was read by James V. Oxtoby, Detroit. A paper entitled "Compensation to Injured Employés—Plan of the New York Edison Company" was read by E. M. Atkin, New York. The technical session was closed with a talk by Dr. Louis Bell, entitled "Lighting in Europe."

The following officers were elected for the ensuing year:

President—W. W. Freeman, Brooklyn, N. Y.

Vice-president — George H. Harries, Washington, D. C.

Secretary—D. L. Huntington, Spokane, Wash.

Treasurer—L. A. Ferguson, Chicago, Ill.

Executive committee—Samuel Insull, Chicago; Charles L. Edgar, Boston; John W. Lieb, Jr., New York; Joseph B. McCall, Philadelphia; Thomas E. Murray, New York.

Meeting of Railway Commissioners.

The annual meeting of the National Association of Railway Commissioners will be held at Washington, D. C., on October 6. This is the twentieth annual convention of the association. It is expected that the Interstate Commerce commissioners, the various commissioners who have been appointed by states throughout the Union, and prominent legislators, railroad men and financiers will be in attendance.

The committee to report on construction and operating expenses of electric railways is composed of James S. Harlan, Interstate Commerce Commission; Milo R. Maltbie, Public Service Commission, First District, New York; J. C. Morris, Ohio; William J. Wood, Indiana; William Kilpatrick, Illinois; Hartford Erickson, Wisconsin; Orasmus R. Fyler, Connecticut.

Pittsburg Section, American Institute of Electrical Engineers.

The September meeting of the Pittsburg (Pa.) section of the American Institute of Electrical Engineers was held in the lecture hall of the Carnegie Institute. The following officers were elected for the ensuing year: Chairman, W. Edgar Reed; secretary, B. P. Rowe; executive committee, C. B. Auel, B. Rutherfoord, F. Uhlenhaut, Jr., C. W. Davis, E. B. Tuttle, Ludwig Hommel.

Mr. Reed has had a broad experience in electrical engineering both in France and in America.

F. D. Newbury abstracted J. L. Woodbridge's paper on "The Application of Storage Batteries to the Regulation of Alternating-Current Systems." He explained how batteries were used in connection with rotary converters having two-part split pole-pieces and also rotary converters having three-part pole-pieces.

R. L. Flanders read a paper on the "Relay Type of Load Regulators for Storage-Battery Systems." He explained by diagrams how beautifully a relay can be used together with a battery to regulate the supply of alternating current through a rotary converter to produce a satisfactory supply of direct current.

P. M. Lincoln said that the idea carried in all electrical engineers' minds was that the ratio of the direct current to alternating current in a rotary converter was fixed; being for two-phase 1 to 0.7 and for three-phase 1 to 0.6. These ratios do not hold exactly and it has been known that by trimming the pole-pieces and giving the proper back charge, the ratios could be modified. The idea of changing the field form in order to change the alternating-current and direct-current ratio is believed to be original with Mr. Woodbridge. The two-part pole-piece rotary has the advantage of combining the functions of a rotary and regulator. The disadvantages are that it will probably be more expensive, have a distorted wave-form, the power-factor can not be made unity, and the conditions are favorable for resonance with large cable systems, and also for hunting.

J. L. Davis discussed Mr. Fessenden's paper on "Wireless Telephony." He explained how the energy began to flow out into space from the antenna harp when the frequency became 85,000 and from that figure on to 100,000 the energy radiated increased from zero to nearly 100 per cent. He also explained the design of a high-frequency generator, the arrangement of Poulsen's arc, and the marginal method of tuning invented by Fessenden.

E. B. Tuttle spoke of the method of relaying telephone messages from wire lines to wireless transmitters, and *vice versa*.

S. P. Grace, in the discussion, spoke of the progress made in telephony. He started with the first form of telephone, that of iron rods driven into the ground outside of forts to indicate to the defenders any attempt of an enemy to tunnel into the fort, and showed what rapid progress had been made in the art. He referred to some early letters on the invention of the telephone written by T. A. Edison to T. B. A. David.

American Society of Mechanical Engineers.

The season of professional meetings of the American Society of Mechanical Engineers will be opened on Tuesday evening, October 13, by a meeting of the Gas Power Section in the Engineering Societies Building at 29 West Thirty-ninth street, New York city.

H. L. Doherty, chairman of the Meetings Committee of the section, will present a report for discussion outlining plans for future work, and there will also be a discussion of standards to be used in gas-power work.

Two papers will be read, one by D. A. Harvev on gas-producer plants, with data upon costs, performance, etc.; and one by N. T. Harrington, giving the results of tests to determine the loss of fuel weight in a freshly charged producer, due to increase of ash contents in the fuel bed. The first paper will be illustrated by lantern slides, showing actual plants and plans for the arrangement of apparatus.

Large Water-Power Development on the Mississippi River.

A 300,000-kilowatt water-power plant is to be erected by Cooper & Powelson at Keokuk, Iowa. The plans contemplate damming the Mississippi River in the rapids at Keokuk. Current for electric light and power is to be supplied to Keokuk, Davenport, Burlington, Rock Island and other manufacturing cities and towns in that district, and eventually to St. Louis, Mo. Mr. Cooper owns the government franchise to build a dam across the Mississippi River at Keokuk.

The Convention of the American Street and Interurban Railway Association.

The annual convention of the American Street and Interurban Railway Association and its affiliated and allied associations will be held at Atlantic City, N. J., October 12, 13, 14, 15 and 16. The American Street and Interurban Railway Manufacturers' Association is making great preparations for a magnificent exhibit, which will cover the entire area of Young's million-dollar pier. One hundred and fifty different companies have already been assigned exhibit space. The association booth for the registration and information of delegates and guests to all of the associations will be located at the Boardwalk entrance to the pier. The manufacturers' association will also have a booth at the same place, which will take care of similar matters relating to the exhibitors and the members of that organization.

All of the meetings of the American association and of the Transportation and Traffic association will be held in the Greek Temple, near the outer end of the convention pier. The Accountants will hold their two sessions on Wednesday, at the Chalfonte Hotel, and their Thursday and Friday sessions in the Aquarium Court Hall, near the Boardwalk end of the convention pier. The Engineers will hold their Tuesday and Wednesday sessions in the Aquarium Court Hall, and their Friday session in the Greek Temple. The Claim Agents will hold all of their sessions at the Traymore Hotel.

The following programme has been announced:

ACCOUNTANTS' ASSOCIATION.

Tuesday, October 13—2 to 5 P. M.—Registration and badges.

Wednesday, October 14—9.30 A. M. to 12.30 P. M.—Convention called to order. Annual address of president. Annual report of executive committee. Annual report of secretary-treasurer. Paper—"Organization of the Accounting Department of an Electric Railway and Light Company," by A. R. Patterson, general auditor Savannah Electric Railway Company, Savannah, Ga. Report of Committee on Collection of Blanks and Forms, by Elmer M. White, secretary Accountants' Association, Brooklyn, N. Y. Appointment of Convention Committee. New business.

Wednesday, October 14—1 P. M.—"Get together luncheon."

Thursday, October 15—9.30 A. M. to 12.30 P. M.—Paper—"Interline Accounting of Interurban Railways," by W. H. Forse, Jr., secretary and treasurer Indiana Union Traction Company, Anderson, Ind. Paper—"Accounting Methods of a Holding Company," by P. S. Young, comptroller Public Service Railway Company, Newark, N. J. Report of Committee on Standard Classification of Accounts and Form of Report. Report of Committee on International Standard Form of Report. Appointment of Nominating Committee.

Friday, October 16—9.30 A. M. to 12.30 P. M.—"The Effect of Electrification on the Accounting Methods of Steam Railways," by A. B. Bierck, general auditor Long Island Consolidated Electrical Companies, Long Island City, N. Y. Reports of Convention Committees. Report of Nominating Committee. Election of officers. Installation of officers. Adjournment.

ENGINEERING ASSOCIATION.

Tuesday, October 13—9.30 A. M. to 12.30 P. M.—Registration and badges.

Tuesday, October 13—2 P. M. to 5 P. M.—Convention called to order. Annual address of president. Annual report of executive committee. Annual report of secretary-treasurer. Appointment of Convention Committees. Report of Committee on Maintenance and Inspection of Electrical Equipment.

Wednesday, October 14—9.30 A. M. to 12.30 P. M.—Report of Committee on Standardization. Report of Committee on Power Generation.

Wednesday, October 14—2 P. M. to 5 P. M.—Report of Committee on Control. Appointment of Nominating Committee. Report of Committee on Power Distribution.

Thursday, October 15—9.30 A. M. to 12.30 P. M.—Inspection of exhibits.

Thursday, October 15—2 P. M. to 5 P. M.—Inspection of exhibits.

Friday, October 16—9.30 A. M. to 12.30 P. M.—Report of Committee on Car and Car-House Wiring. Report of Committee on Operating and Storage Car-House Designs. Question box.

Friday, October 16—2 P. M. to 5 P. M.—Report of Committee on Way Matters. Report of Committee on Economical Maintenance. General business. Report of Nominating Committee. Election of officers. Installation of officers. Adjournment.

CLAIM AGENTS' ASSOCIATION.

Monday, October 12—9.30 A. M. to 12.30 P. M.—Registration and badges.

Monday, October 12—2 P. M. to 5 P. M.—Convention called to order. Annual address of the president. Annual report of the executive committee. Annual report of the secretary-treasurer. Appointment of Convention Committees.

Tuesday, October 13—9.30 A. M. to 12.30 P. M.—Paper—"The Organization of a Claim Department for a Small or Moderately Large Company, Including a School of Instruction as a Means of Preventing Accidents," by Francis J. Ryan, M.D., Syracuse Rapid Transit Railway Company, Syracuse, N. Y. Paper—"The Claim and Its Disposition," by Peter C. Nickel, claim agent New York City Railway Company, New York, N. Y.

Tuesday, October 13—2 P. M. to 5 P. M.—Paper—"Uniformity in Claim Department Records and Accounts," by John J. Reynolds, claim agent, Boston Elevated Railway Company, Boston, Mass. Paper —"The Duties of Claim Agents and Other Officials of Quasi-Public Corporations to the Public," by Eugene R. Roberts, attorney Knoxville Railway and Light Company, Knoxville, Tenn. Appointment of Nominating Committee.

Tuesday, October 13—8 P. M.—Social smoker and entertainment. (Place to be announced later.)

Wednesday, October 14—9.30 A. M. to 12.30 P. M.—Question box. Discussion—"The Medical Side of the Prevention of Accidents." General business. Reports of Convention Committees. Report of Nominating Committee. Election of officers. Installation of officers. Adjournment.

TRANSPORTATION AND TRAFFIC ASSOCIATION.

Monday, October 12—9.30 A. M. to 12.30 P. M.—Registration and badges.

Monday, October 12—2 P. M. to 5 P. M. —Convention called to order. Congratulatory address by Hon. W. Caryl Ely. Annual address of the president. Report of organization meeting. Annual report of the executive committee. Annual report of the secretary-treasurer. Appointment of Convention Committees. Reports of special committees. Paper—"How Can a Small Road Best Promote Traffic and Increase Its Revenue?" by Ernest Gonzenbach, general manager Sheboygan Light, Power and Railway Company, Sheboygan, Wis. Report of Committee on Training of Employés.

Tuesday, October 13—9.30 A. M. to 12.30 P. M.—Paper—"Carrying of United States Mail on Electric Railways, Its Advantages and Disadvantages, and the Compensation Therefor," by C. H. Hile, assistant to vice-president Boston Elevated Railway Company, Boston, Mass. Report of Committee on Freight and Express. Paper—"Progress to Date in Carrying Freight and Express Matter by Electric Roads—Some Mistakes That Have Been Made and Their Remedy," by C. V. Wood, general freight and passenger agent New England Investment and Security Company, Boston, Mass.

Wednesday, October 14—9.30 A. M. to 12.30 P. M.—Appointment of Committee on Nominations. Symposium—"The Possibilities of a Well-Conducted Publicity Department," by George Sabin Brush, clerk Transportation Department Boston Elevated Railway Company, Boston, Mass. B. R. Stephens, general traffic manager Illinois Traction System, Springfield, Ill. Charles E. Flagg, department of publicity Inland Empire System, Spokane, Wash. George H. Gall, publicity manager Washington, Baltimore & Annapolis Electric Railway Company, Baltimore, Md. Charles W. Lamb, advertising expert, Milwaukee, Wis. Report of Committee on Interurban Rules.

Thursday, October 15—9.30 A. M. to 12.30 P. M.—Paper—"The Operation of Multiple-Car Trains on Interurban Roads," by D. F. Carver, receiver Trenton & New Brunswick Railroad Company, Trenton, N. J. Report of Committee on Passenger Traffic. Report of Committee on Rules for City Operation. General business. Report of Nominating Committee. Election of officers. Installation of officers. Adjournment.

Canadian Bell Telephone Company Extending Its System.

It is announced at Montreal, Quebec, that the Bell Telephone Company will spend $1,000,000 in improving the company's service in Ontario and Quebec. The company is building through lines from Toronto to North Bay, a distance of 230 miles, to connect at the latter point with the Ontario Government system to the new districts of Ontario. Another line from Toronto to Parry Sound will be constructed to embrace a number of summer resorts in the Muskoka lakes district. An additional telephone line direct between Montreal and Quebec has been completed.

In Montreal the Bell Telephone Company is erecting a new exchange building in the north end to be known as the St. Louis exchange. In Toronto the company will put up a building, five stories high, sufficient to accommodate 20,000 subscribers. All long-distance work will be centred in this building. At Quebec a large addition is being built to the present exchange, which will be ready for occupation in about three months.

Modern Science Club.

The Modern Science Club will open its winter season at the club house, 125 South Elliott Place, Brooklyn, N. Y., with a smoker and entertainment on Tuesday evening, September 29.

The following announcements are made for the first month of the lecture course: October 6, Almet R. Latson, president of the Union League Club, of Brooklyn, will deliver an address entitled "The Sources of Our Law"; October 13, quarterly meeting of the club; October 20, Emil F. Jennert, superintendent of the Manhattan Brass Company, will deliver an address entitled "Voting Machines"; October 28, George A. Orrock, mechanical engineer of the New York Edison Company, will deliver an address entitled "Central Station Design."

Memorial to Alexander Graham Bell.

The people of Brantford, Ontario, have raised the sum of $40,000 for a memorial to Professor Alexander Graham Bell. It was just outside of the city that Professor Bell made his first successful experiments with the telephone, and Brantford has since been known as the "Telephone City." With the money subscribed several blocks of land in the centre of the city have been purchased and will be turned into public parks.

The October Meeting of the American Institute of Electrical Engineers.

The October meeting of the American Institute of Electrical Engineers will be held in the Auditorium of the Engineering Societies Building, 33 West Thirty-ninth street, New York city, on Friday, October 9, at 8 P. M. At this meeting a paper entitled "High-Potential Underground Transmission," by P. Junkersfeld and E. O. Schweitzer, of the Commonwealth Edison Company, Chicago, will be presented and discussed.

National Electric Lamp Association to Establish a Department of Physical Research.

The engineering department of the National Electric Lamp Association, Cleveland, Ohio, announces that Dr. Edward P. Hyde, now of the Bureau of Standards, Washington, D. C., after October 1 will organize and direct a department of physical research under the auspices of, and at the expense of, the association. Dr. Hyde will operate his department with entire freedom from commercial suggestion, and with the same frank publicity which has characterized his work at the Bureau of Standards.

The British Association Meeting.

The annual meeting of the British Association for the Advancement of Science was opened in Dublin, Ireland, on Wednesday, September 2, at the reception given to the council and delegates by the Lord Mayor and Lady Mayoress. The formal sessions began on Wednesday evening with the address of Francis Darwin, president of the association, in the course of which Mr. Darwin paid a touching tribute to the late Lord Kelvin, and stated that all kinds and classes of people alike lamented his recent death.

On the morning of Thursday, September 3, Dr. W. N. Shaw delivered his presidential address to Section A (mathematical and physical science). This address dealt almost entirely with meteorology. The remainder of this section's proceedings was of little interest to electrical engineers, with the exception of the report presented by Dr. R. T. Glazebrook, of the Electrical Standards Committee.

Section G (engineering) listened to the address by Dugald Clerk, its president. This dealt with the discovery and development of the laws of thermodynamics. A portion of the address is printed elsewhere in this issue. Gerald Stoney read a paper entitled "Recent Advances in Steam Turbines." The great progress which had been made in the building of turbines was called attention to. The largest steam turbine made in 1900 had a rated output of 1,000 kilowatts, while to-day there are quite a number of turbines installed with outputs ranging from 5,000 to 8,000 kilowatts.

On the morning of Friday, September 4, a joint meeting of Sections A, B and G was held, the topic for discussion being entitled "Gaseous Explosions." During the discussion of this subject Mr. Clerk stated that he had made some experiments with a view to ascertaining how completely combustion was effected when the gaseous mixture was exploded. With a mixture of one part of gas to seven of air he found that two and one-half per cent of the gas had not undergone combustion, and that the same figure applied to a one-in-ten mixture. He was of the opinion, however, that if a higher degree of accuracy could have been obtained, the percentage of unconsumed gas would have been five or six.

Sir William Ramsay read a paper entitled "Do the Radioactive Gases (Emanations) Belong to the Argon Series?" A paper entitled "On the Number and Absorption of the Beta Particles Emitted by Radium" was read by W. Makower. A paper entitled "The Rate of Production of Helium from Radium" was read by Sir J. Dewar.

On the morning of Monday, September 7, Section A opened its session by a discussion of the topic "Theory of Wave Motion," introduced by Professor Horace Lamb. A paper entitled "On the Measurement of Large Inductances Containing Iron" was presented by Sir Oliver Lodge and Benjamin Davies.

Section G listened to the reading of three papers concerning gas production and use. These papers are as follows: "The Utilization of Peat for Making Gas or Charcoal with Recovery of By-Products," by Captain H. R. Sankey; "Producer Gas," by J. Emerson Dowson, and "Suction Gas Producers," by P. W. Robson. This session was concluded by the reading of a paper entitled "The Study of Breakages," by R. Rosenhain, and a paper entitled "The Electrical Conductivity of Certain Light Aluminum Alloys, as Affected by Exposure to London Atmosphere," by Professor E. Wilson.

On Tuesday, September 8, Professor E. Rutherford read a paper entitled "The Scintillations of Zinc Sulphide," before Section A. This was followed by a paper by Horace H. Poole, entitled "A Determination of the Rate of Evolution of Heat by Pitchblende."

Section G listened to a paper entitled "The Laws of Flight," by F. W. Lanchester, and a paper entitled "The Causes of Wear in Motor Vehicle Machinery," by F. H. Royce.

The session of Section A on Wednesday, September 9, was devoted to meteorological subjects, and Section G listened to the reading of a paper by J. Brown and M. F. Fitzgerald, entitled "Experiments on Rotating Discs." This paper was followed by the closing paper, entitled "Urban and Suburban Transit and Methods of Railless Traction," by F. Douglas Fox.

The informal sessions were concluded on the afternoon of Wednesday, September 9, by a garden party given to the members of the association by the Lord Lieutenant at the vice-regal lodge.

New Wireless Test.

It is stated that Lee De Forest has arranged with the British Admiralty for exhaustive tests of his wireless telephone system. The experiments are expected to occupy several weeks.

Electrification Plans of the Delaware, Lackawanna & Western.

It is announced that electrification of the Delaware, Lackawanna & Western system from Hoboken to Morristown, N. J., will take place shortly after January 1. Plans are in readiness for making the change in motive power over the stretch of thirty-two miles, and actual work will begin as soon as the new tunnel through Bergen Hill is finished. This tunnel, which has been building for two years, will open for traffic on November 15. All grade crossings along the line will be abolished first and the tracks through the Oranges will be depressed. Motor-cars will be ordered which will be of a different type from the electric locomotives on the New York Central. These will draw the regular trains from Hoboken to Morristown, where the change to steam will be made on the trains running to Buffalo.

All told the cost of the various operations, including the tunnel, electrification, new cut-off at Lake Hopatcong and additional track laying, will total more than $25,000,000. This amount will be spent in three years' time.

New York Edison-Philadelphia Electric Outing.

Arrangements have been completed for a baseball game between the employés of the New York Edison Company and the Philadelphia Electric Company, to be held at the American League Grounds in Philadelphia, Pa., on Saturday, September 26.

A special train will leave West Twenty-third street, New York city, at 11.55 A. M.; Cortlandt and Desbrosses streets at 12 M., arriving at Broad Street Station, Philadelphia, at 2 P. M. Transportation to the grounds will be arranged for by the Philadelphia Electric Company, who will also furnish a collation and music at the finish of the game.

Illinois Central Electrification.

An exhaustive report, about completed, by the chiefs of various city departments of Chicago, Ill., on railroad electrification estimates the cost to the Illinois Central at $5,000,000. J. T. Harahan, president of the Illinois Central, says he will study every phase of the electrification problem and reach a decision as soon as possible. Louis C. Fritch, assistant to Mr. Harahan, is inspecting the operating conditions of the terminals electrified by the New York Central.

A UNIQUE WATER-POWER PLANT.

BY H. LESTER HAMILTON.

Probably at no other time in the history of the world has the subject of power and its efficient utilization been given so much attention as at the present. Scientists tell us that in a comparatively short time the rapid depletion of our coal deposits will necessitate the adoption of more efficient methods of transforming this latent energy. Mighty rivers, on whose bosoms could float the largest battleships, have been dammed to furnish power for hydroelectric plants, and countless Niagaras the world over are being enlisted in the same cause. Projects for utilizing the mighty power of the ocean waves are daily launched, and we occasionally read of some scientist who proposes to harness the potential energy of the thunder cloud in order that we may have a perpetual supply of electricity.

But how many of us, while listening to the murmur of the rippling brook, think of it as a power producer? Yet in the small streams of our country the energy of thousands of horse-power is daily going to waste, and all for the want of proper development. The cost of developing a water power of this nature is comparatively small, yet those who are in a position to reap the benefits which would be derived therefrom rarely take advantage of the opportunity. This condition of affairs may be attributed to one of two things: ignorance of the real value of the water power or lack of initiative.

This spirit of lethargy has, however, been shaken off in some parts of the country and enterprising persons have awakened to the latent power possibilities existing in nearby streams. Among this class the farmers are in the van, and not a few have harnessed their meadow brooks and are now enjoying luxuries which were not possible before.

Where the natural features are such that it is practicable to secure a considerable pondage and a fair head of water, a comparatively small stream can be made very valuable to the farmer. A water turbine can be installed to run a gristmill or sawmill during the daytime, the belt being shifted over at night to run a small dynamo for lighting the house and outbuildings. If the pond has sufficient capacity, the dynamo could also be run during the daytime to supply power for operating cream separators, cutting feed, elevating ensilage and hay, and for performing various other farm duties. During the winter months the surplus energy could be used for heating the house. Carrying it a little further, the laundry irons could be electrically heated, the sewing machine and ice-cream freezer motor-driven; chickens could be hatched in the electric incubator, the cows milked by a motor-driven automatic milker, and instead of carrying produce to town in the slow, creaky farm wagon, the swift, noiseless electric automobile could cover the distance in a third of the time. Ideal! Yes, but entirely possible to the fortunate possessor of a suitable water power.

A General View of the Mill Pond, Looking Up from the Dam.

An excellent example of the profitable utilization of a small water power, and one unique in some features, is found in the power plant of Christ School. This model school, nestled away among the hills of western North Carolina, commonly known as the "Land of the Sky," and not far from the city of Asheville, is almost a village in itself. There are several dormitories, an assembly hall, a chapel containing a miniature pipe organ, several workshops, and neat little cottages for the instructors. Not only is the mind trained, but the pupils are instructed in farm work, wood-working and domestic work as well. The making of beds and the sweeping of floors are as important a part of the daily routine as the memorizing of rules for extracting the cube root of a number. "The Galax Leaf," a little magazine published and printed by the students, is widely read by those interested

Looking Toward the Top of the Dam, and Showing the Building Containing the Grist Mill, Saw Mill and Dynamo Room.

A View Taken Below the Dam, Showing a Part of the Power-House on the Right.

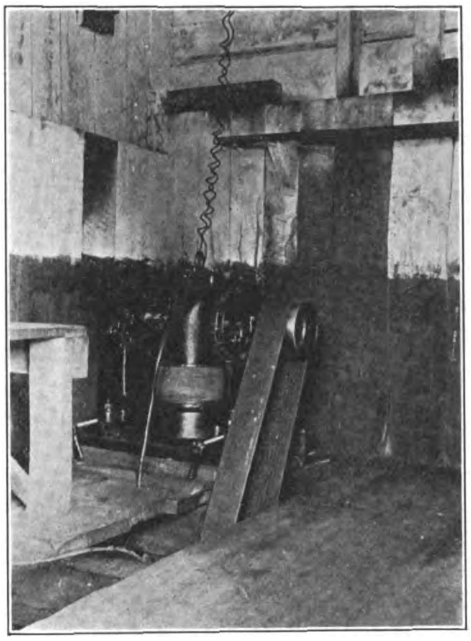
in the progress of the school. Not far from the school and down in the valley runs a little brook, rushing and tumbling through the fields, as is typical of most mountain streams. For years it had merrily gurgled its way over the pebbly bottom, occasionally bestirring itself to wash away the corn planted on its banks or to hollow out inviting swimming holes for the boys, but several years ago a progressive principal who was placed in charge of the school saw that by building a suitable dam across the brook enough water could be impounded to run a sawmill and a gristmill. The services of a local engineer were accordingly enlisted and a twenty-foot dam of rubble masonry was built, forming a pond some five acres in area.

An eight-horse-power water turbine of the horizontal type, together with the machinery for the gristmill and sawmill, was installed in a frame building just below the dam, the upper side of the structure forming part of the retaining wall. This building was later extended to make room for a small dynamo. During the daytime either the sawmill or the gristmill is operated, provision being made so that the belt can be shifted from one line shafting to the other. At night the belt is transferred to the pulley of the dynamo.

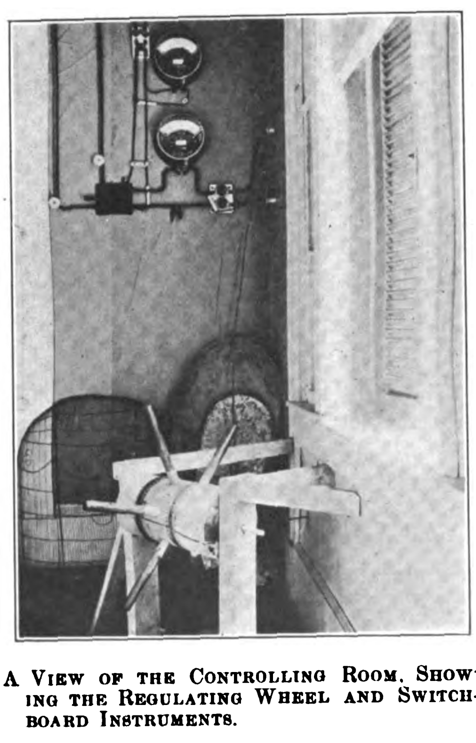
The sawmill, while not very complicated or of the latest design, manages to turn out very creditable work. The machines in use consist of a circular saw for ripping out rough boards from the logs as they are skidded into the mill, a cutoff saw for reducing them to a uniform length, and a combination planer and molder which converts them into flooring or plain boards, as the case may be.

In the gristmill the corn and wheat, which are planted, cultivated and harvested by the pupils of the school, are ground and sacked ready for the market. A small proportion of the total grain crop is made up into bread and baked by these same students, the remainder being sold at a neat profit to Asheville merchants, who are always glad to buy the product of the Christ School mill.

The electrical end of the installation presents several interesting features. The dynamo, which is five kilowatts, or a little over six horse-power in capacity, is a two-pole direct-current machine giving forty amperes at 125 volts when driven at a speed of 1,100 revolutions per minute. Running under normal load it supplies current to some eighty-five sixteen-candle-power incandescent lamps in the various buildings on the hill. Owing to the character of the load, which is always steady, and the constant supply of water, due to the large area of the pond, no governor is needed other than a simple hand-wheel connected by a short iron rod to the gate valve of the turbine. The forward or backward turning of this hand-wheel varies the amount of water supplied to the turbine and enables quite a range of speed to be obtained. It is sometimes necessary to change the speed in the mill, especially when sawing different kinds of timber.



A View of the Dynamo Room.



A View of the Controlling Room, Showing the Regulating Wheel and Switchboard Instruments.

As the power plant is about one-third of a mile from the school, it was out of the question to go there at night to start and stop the machinery, and the expense of keeping an attendant did not seem justified. Neither did it seem advisable to allow the dynamo to run all night, as something might happen to stop the flow of oil to the bearings, in which case the machine might be seriously damaged. For this reason the following method of "remote control" was adopted:

On top of the hand-wheel regulating the water supply of the turbine, and securely fastened to it, is placed perpendicularly a wooden cylinder, about eight inches in diameter and a foot long. A small chain is wrapped several times around the cylinder, the ends of the chain being carried out through the side of the house, where they are fastened to two small iron wires, telephone wires, in fact. These wires extend along the transmission line to the principal's house, terminating in a room which might appropriately be called "the controlling room." At each pole the wires are strung through small pulleys in order to keep the friction down, the pulleys also serving as guides for the wires.

In the controlling room is placed a capstan or windlass, in appearance similar to the steering wheel of a ship, and around which the wires are fastened in the same manner as in the power-house. In other words, the controlling system consists of an endless chain fastened at each end to a movable cylinder, the cylinder fastened to the valve rod of the turbine moving in response to a movement of the cylinder in the principal's house, 1,700 feet away. Contrary to all expectations, this system of control has never caused the slightest trouble, not even during the trying winter months when the wires were covered with sleet and snow.

The controlling room is also the switchboard and distribution room, as here the transmission line from the power-house, after passing through a main switch, branches off to the various dormitories. An ammeter and voltmeter are the only indicating instruments, the switchboard equipment being completed by the necessary protective fuses and distributing switches.

The method of procedure in starting up is very simple. The wheel in the controlling room is turned until the voltmeter indicates that the dynamo has begun to generate. The different switches are then closed and further turning of the wheel, as soon as the ammeter shows that the dynamo has "picked up" its load, speeds the machine up until the voltmeter registers 110 volts. To allow for drop in voltage on the various lines running to the dormitories, the needle of the voltmeter is generally held a little higher than this value.

It is very seldom that the voltage varies enough to be noticeable in the lamps, but should it do so, only a turn of the regulating wheel is required to bring it back to normal. At half-past ten, when the "lights-out" bell is rung, a few turns of the wheel quickly slow the dynamo down, and darkness reigns.

The remarkable success that has attended the operation of this little plant leads those in authority to believe that a much larger turbine and dynamo could be installed to advantage, and plans are being made to utilize this extra energy in heating the dormitories, furnishing power for a motor-driven fire pump and for various other operations around the school and on the farm. When these plans mature the Christ School power plant will stand as a monument to the energy and farsightedness of the man who first realized the true value of the little meadow brook, and it should act as an incentive to less enterprising owners of equally valuable water power. Even in its present condition it is an excellent example of what is possible to be accomplished by the proper development of small water powers.

Electrical Equipment for Santos Dock Company, Brazil.

The Santos Dock Company through whose docks most of the coffee exported from Brazil passes, has recently received from the General Electric Company complete generating station equipment—five revolving field, 3,000-kilowatt, 2,300-volt, three-phase, sixty-cycle, alternating-current generators; 350-kilowatt exciters; fifteen 1,000-kilowatt, step-up transformers, transforming generator voltage to 44,000 volts, with complete switchboard of most modern construction.

Some time ago a comprehensive order, including complete substation equipment, wiring and lighting supplies, and a large number of induction motors for operating air-compressors, hoists, cranes, etc., was received from the Santos Dock Company. This apparatus is now being shipped to Brazil.

The hydroelectric plant is located some thirty-five miles from the substation and, besides furnishing power for operating all the machinery at the docks, will also supply energy for light and power to various other industrial enterprises near the city.

THE KOKOMO, MARION & WESTERN TRACTION COMPANY.

BY C. A. TUPPER.

As an illustration of what may be accomplished in building up an existing electric railway, lighting and power distributing system, and at the same time strengthening the industrial position of an entire community, the management of the Kokomo, Marion & Western Traction Company furnishes one of the most striking and instructive examples to be met with anywhere in the country. At the time ownership of the system was assumed by the interests now in control, less than four years ago, there was a small street railway and electric lighting plant, having no greater output than 500 kilowatts, a few miles of trackage wholly within the city of Kokomo, and circuits containing several hundred arc and incandescent lamps. To-day 22,000 incandescent and 395 arc lamps in and about Kokomo are supplied with electric current and more than one-half of the company's customers have various electric household devices; factories in the vicinity take upward of 1,000 horse-power daily in current for operating motors; the street railway system has been extended to a trackage of ten miles, and a finely equipped interurban line of twenty-eight miles in length extends from Kokomo, a city of about 18,000 inhabitants, to Marion, having a population of 26,000, through several large towns situated in a rich, closely tilled agricultural country. Further extensions are projected to Terre Haute and Lafayette on the west, distant respectively, 130 and seventy-nine miles from the eastern terminus of the road. Among the principal places on the line now in operation are: Georgetown and Swayzee, each of about 2,000 people; Sycamore, Sims, Herbst and Roseberg.

Among outward signs of progress, however, the most prominent is the development of the new power station, which has recently been equipped with two Allis-Chalmers steam turbines and generators having an aggregate normal capacity of 2,000 kilowatts and delivering two-phase, sixty-cycle current at a terminal pressure of 2,300 volts. The first of these machines, put in operation February 21, 1907, was found so satisfactory that a second unit of identical construction was ordered, the latter being placed on the line December 7 of the same year.

Coal, consisting of a comparatively low grade of Indiana screenings, is brought in on a spur from the Lake Erie & Western Railway and unloaded through a trestle extending the entire length of the firing room, so that it is heaped up in front of iron doors opening upon the several furnaces. From these piles it is shoveled directly into the furnaces, which are so arranged as to obtain a relatively high heat value from the fuel—with the exercise of good management. Removal of ashes is accomplished by an inexpensive device. Instead of the customary ash pit with tracks and cars, there has been installed a tunnel and screw conveyer through which the ashes are constantly transferred to a pit outside the building. There, by means of a bucket elevator and inclined conveyer, the material is discharged to storage bins at one side of the building and unloaded into cars, which take it to points along the line where it can be used as ballast.

The boiler equipment, set on concrete foundations reaching to bed rock, consists of three batteries, two of which include four Stirling boilers, each having a capacity of 235 horse-power, and the third comprising one Atlas water-tube boiler with a capacity of 400 horse-power. Two of the Stirling boilers discharge into one stack six feet by eighty feet, constructed entirely of steel, and the remaining two, with the Atlas boiler, into a stack six feet by 125 feet, also of steel. The shorter of these stacks is equipped with an engine-driven blower, made by the B. F. Sturtevant Company, by means of which enough draft can be induced to give large temporary overload capacity to the two boilers with which it is connected. The boiler room has ventilators at the top and is very commodious with room for considerable additional capacity.

A main header, twelve inches in diameter, located above the pump compartment in the steam-turbine room, is in the form of a loop, from which each turbine unit is fed by a seven-inch pipe. Gate valves are placed between each battery of boilers and between each turbine inlet, these valves being of the Crane type with rising stems. There is also a four-and-one-half-inch auxiliary header. A proper arrangement of valves enables any part of the plant to be supplied from any boiler at will. All of the piping is made as short and direct as possible and heat insulation is provided in the shape of heavy covering of the pattern furnished by the H. W. Johns-Manville Company. Long bends to provide for expansion have, of course, been used wherever necessary, and the system includes Cochrane steam separators.

The condensers and all of the other

auxiliaries exhaust into a Cochrane heater (with Sorge water purifier) where a temperature of from 200 degrees to 212 degrees Fahrenheit—never less than 200 degrees—is maintained constantly. Water may be drawn from either the condenser suction or discharge pipes, from a deep well or from the city mains, and discharged into an elevated tank which feeds by gravity into the heater and from there by gravity into the boiler feed pumps; or the water may be by-passed directly to the boiler.

Two Worthington pumps are used for supplying the tank over the heater and two Dean pumps for boiler feed. Either one of any of these two is, however, of sufficient capacity to take care of the water system of the entire plant. The former are now being displaced by a centrifugal pump with two-and-one-half-inch discharge, driven by an induction motor supplied with current directly from the main generator buses through a step-down transformer; but the steam pumps will be held in reserve.

Water for condensation and boiler feed is taken from a creek, about 350 feet distant, through a sixteen-inch cast-iron pipe. and discharged back to the stream through twenty-inch tile. The water is drawn from a concrete basin in the creek, seven feet square inside and extending six feet below low-water mark, with walls extending to high-water mark and a gate on the down-stream side where the water enters. This gate can readily be closed down tight when desired and the water exhausted by pumps in the power plant, so as to facilitate cleaning the basin of sand and mud.

The turbine-operating floor is five and one-half feet above the boiler and pump-room floor, eleven feet above the basement floor and thirty feet below the roof trusses, the foundation of each generating unit being kept entirely separate from the steel frame of the concrete flooring. Overhead is a ten-ton crane, hand operated. In this room are placed two horizontal steam turbines and generators of 1,000 kilowatts capacity each, a 330-kilowatt engine-driven alternator operated in parallel with them, the exciters for these units, and substation apparatus, transformers, switchboard, etc.

Incorporated in these turbines are the various patented features controlled by the builders, the Allis-Chalmers Company, among which may be mentioned channel-shaped shrouds protecting the ends of the blading from injury; machine-cut slots in the foundation rings insuring accurate spacing of the blades; a method of fastening the latter which effectually prevents them from working loose, and improved balance pistons.

The turbines operate at 1,800 revolutions per minute, with a steam pressure of 140 pounds at the throttle, dry saturated, and a vacuum of twenty-eight inches of mercury referred to thirty inches barometer at the exhaust nozzle. Large temporary overload capacity has been provided for in the design of these machines; high efficiency is maintained, and close regulation secured under unfavorable operating conditions as a result both of good design and efficient station management. They are frequently run six weeks at a time without taking the load off and then only to make inspection.

The bedplate is divided into two parts, one carrying the low-pressure end of the turbines and the bearings of the generator, and the other the high-pressure end of the turbine. The turbine is secured to the former, while the latter is provided with guides which permit the turbine to slide back and forth with differences of expansion caused by varying temperature, at the same time maintaining the alignment. This arrangement permits of the utilization of the entire space between the foundation piers and below the turbine for the condensing apparatus. A grating is provided in the engine-room floor, directly over the condenser pumps and engines, so that operators above and below can watch each other's movements and signals, and the auxiliary engines can ordinarily be watched from above.

The condensers for the steam turbines are of the jet type built by Allis-Chalmers Company, each capable of giving the best possible service when its unit is operating at full rated load. Cycloidal air-pumps, direct-connected to enclosed, self-oiling, high-speed engines, and duplex, double-acting circulating pumps are installed with this apparatus, as is also a third condenser to take the exhaust from the remainder of the plant.

The speed of each turbine is regulated within close limits by a governor driven from the shaft through cut gears working in an oil bath. This governor, by means of a relay, operates a balanced throttle valve.

The lubrication of the four bearings, two for the turbine and two for the generator, is effected by supplying an abundance of oil to the middle of each bearing by means of a small cycloidal pump driven from the turbine shaft, and allowing it to flow out at the ends.

TURBO-GENERATORS.

The revolving-field alternators driven by these turbines are of Allis-Chalmers Company's standard type, designed for high efficiency and safe operation at high peripheral speeds. The field core is built up of steel discs, each in one piece, giving high magnetic permeability and great strength. Coils are placed in radial slots, avoiding side pressure on slot insulation and the complex stresses resulting from centrifugal force, which, in these rotors, acts normal to the flat surface of the strip windings. Bronze wedges hold the coils firmly in the slots, making the surface of the rotor a smooth cylinder, reducing windage losses and insuring quick operation; and the end connections are securely held by chrome nickel-steel rings. The stator is completely inclosed. Coils were wound and insulated before being placed on the core. Stator windings are placed in open slots and end connections are firmly braced.

Excitation of the two turbo-generators is accomplished by means of exciters of thirty-five kilowatts and thirty kilowatts, the former being driven by an Allis-Chalmers induction motor and the latter by an Erie Ball engine. The engine-driven unit has a five-kilowatt belted exciter. Turbo-generator excitation at full load is at 120 volts, 160 amperes. The exciters do not take care of the station lighting. Current for this is derived directly from the main bus-bars, or from a storage battery.

The character of the load put upon this station is railway, lighting and power combined. At present there is a normal consumption of current somewhat under the rated capacity of the turbines, so that one can be held constantly in reserve, and this drops to a minimum during the early morning hours of about 300 kilowatts.

A feature to be particularly commended is the thorough keeping of station records and the frequent checking of efficiencies of different parts of the plant. On the company's log sheet the daily load curve is plotted, thereby enabling it to be easily comprehended, for the twenty-four hours, at a glance. All costs and station performances are also recorded on the daily log. In addition to this records are kept in the office of the outside distributing circuits, and two Wright demand meters are constantly used to check the loads on lighting and power transformers over the town.

Alternating current is generated at two-phase, 2,300 volts, and transformed to three-phase, 11,000 volts, for transmission over the line of the interurban railway. In the main station there are used for this purpose three 150-kilowatt, oil-filled, self-cooled transformers, Scott connected, and in the substation (seventeen miles distant) there are three 150-kilowatt step-down transformers, delta connected. These transformers have one-and-one-half-inch outlet pipes run directly through the floor, so that in case of fire oil can be emptied into barrels in the basement where the oil supplied is stored.

Direct current for the city railway system and ten miles of the interurban line is supplied through motor generator sets in the main station, delivering power at an operating pressure of 600 volts; and the substation at Swayzee, eighteen miles east of Kokomo, contains three rotary converters for the purpose of transforming the alternating to direct current. One of these, having a capacity of 200 kilowatts, is equipped with an induction starting motor, and two of seventy-five kilowatts each are started through a storage battery from the direct-current end.

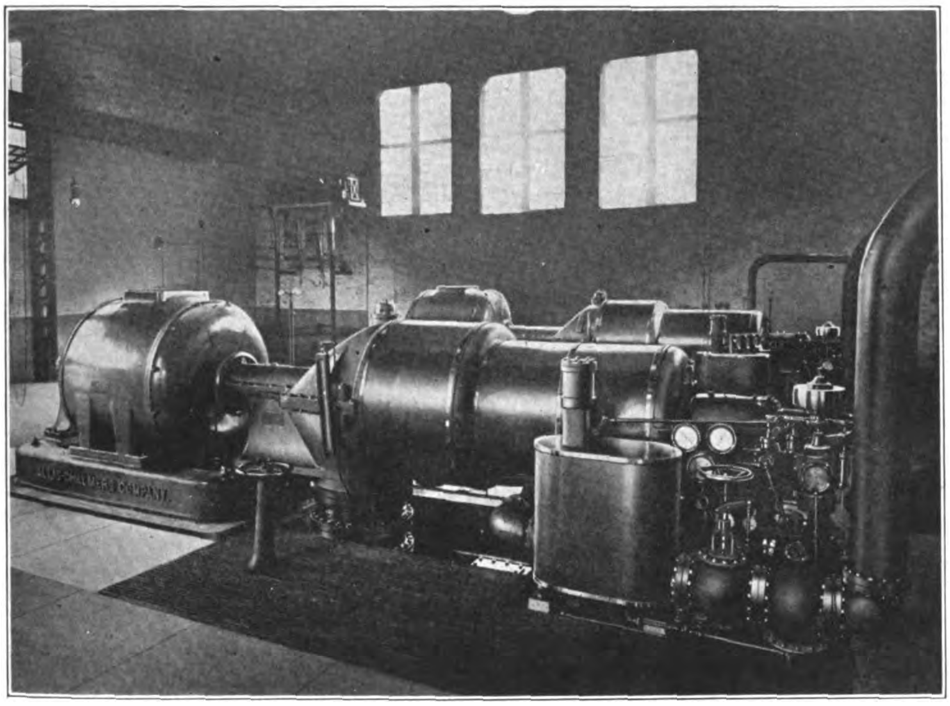
Current from the main generator busbars passes to the outgoing lines through double-throw switches, ammeters, wattmeters and fuses, all such circuits being also put through integrating wattmeters, 300,000-circular-mil cable being used, with high-voltage rubber insulation. The wiring from the generators to the switchboard is open work, fastened to the underside of the engine-room floor. The busbar system is in duplicate. Any machine or any feeder can be operated off of any set of buses. The switchboard rests on insulated stringers, with a panel and necessary apparatus for each turbo-generator and exciter.

The railway board consists of two panels, each controlling a 216-horse-power motor, and two panels each controlling the railway generators driven by these motors in the power plant substation. One panel contains the starting devices and a rheostat for these machines. There are also two feeder panels, one feeding the interurban line and the other on the city line.

Two panels control a storage battery and differential booster.

In a separate building, located about sixty feet from the main generating station, is a battery installation supplied by the Electric Storage Battery Company, which has a capacity of 480 ampere-hours and consists of 288 chloride accumulator cells. A smaller storage battery, consisting of the same number of cells, but having a capacity of 320 ampere-hours, is installed in the substation at Swayzee.

The lines are equipped with Westinghouse low-equivalent arresters and Westinghouse choke-coils, to which ready access is had from the gallery. The lighting feeders have General Electric lightning arresters and choke-coils manufactured at the station. On the direct-current railway system Garton lightning arresters are used, there being four of these to every mile. Wirt lightning arresters are provided at each transformer on the lighting circuit.



Two 1,000-Kilowatt, 1,800-Revolution-Per-Minute, Sixty-Cycle, Allis-Chalmers Steam Turbines and Generators Installed in Power-House of the Kokomo, Marion & Western Traction Company, Kokomo, Ind.

The line of interurban road is built with easy curves and a maximum grade of no more than two degrees, most of the track being laid on the level. The right of way is forty feet wide and owned entirely by the company. Seventy-pound A. S. C. E. rail is used, joined by six-bolt standard splice bars.

The bonds are of the Ohio Brass Company's manufacture and consist of 0000 compressed bonds and soldered bonds on the interurban line and 00 compressed bonds on the city tracks. Rails are cross-bonded every half mile with 0000 copper wire.

The road is ballasted with crushed stone and gravel six inches deep, underneath the ties, 1,000 cubic yards of stone and 300 cubic yards of gravel being used to the mile. The ties are of white oak. Side-arm construction has been used for the entire course of the line, cedar poles being placed along ten miles of the interurban system, chestnut poles on the remaining eighteen miles and cedar and iron poles in the city. The brackets are nine feet, with one-and-one-half-inch tubing made by the Ohio Brass Company. The lightning arresters, four to the mile, are grounded by means of No. 4 copper wire and three-quarter-inch iron rods driven into the ground by the side of the pole and also connected to the rail. The wires consist of two 000 trolleys suspended by the Ohio Brass Company's Type "D" hangers. The feeder wires are 300,000 and 500,000 circular mil copper line feeding on to the interurban wires ten miles from the power station. The feeder from the substation is stranded aluminum equivalent to 300,000 circular mil copper. Spans are 100 feet in length.

There is a bridge crossing the Wildcat Creek near Greentown and there are two overhead railway crossings and several small steel culverts. The high-tension wires cross the bridges on timber projections at the sides of the bridge, the trolley wires being supported from stands fastened to the overhead steel work. At Marion the crossings which span the Pennsylvania and Chicago, Cincinnati & Louisville railways are of the girder type.

Everything connected with the physical equipment of the system has been very carefully looked after, and one of the best evidences of this is the power-house itself, which is a well-planned, well-built fireproof structure. The exterior walls are faced with standard pressed brick, laid in three-quarters English bond with headers in each fourth course, affording a thorough bond into the wall. All of the interior surfaces in the engine room which have not been enameled are faced with Kokomo pressed sand brick of buff color and the remaining brickwork is of the ordinary kiln-run quality. Tile roofing covers the building.

The lighting system of the company has developed at an almost incredible rate. One feeder now goes out from the power station to the North Kokomo distribution system and another supplies South Kokomo, each being fed from the 2,200-volt, two-phase primary circuits; and in addition there are four series alternating-current arc circuits of fifty lights each, fed from transformers at 4,000 volts. The towns of Swayzee and Greentown are both furnished with lighting current taken through transformers from the high-tension lines and stepped down to 220 volts.

A stone quarry, which was originally owned and operated by the company in order to provide crushed rock for ballast, but has since passed into the possession of others, is located on the line of the interurban railway, and the larger part of the product of the plant, about 300 cubic yards per day, is transported by the company to the steam roads and out into various parts of the state for use in improving town and country roads. All of the machinery of this quarry used in crushing, elevating, etc., as well as of another quarry having similar capacity, is operated by motors running on alternating current taken from the power circuits.

Among other important customers taking power for motors are a brass works and spark-coil factory, two machine shops, a large flour mill, an automobile manufactory, bottling works, leather and harness establishment, glass factory, canners, planing mill, cooperage plant, mitten works, lumber yards, and nearly all of the smaller factories and shops in Kokomo, representing no less than eighty-four distinct industries. The use of small single motors and groups of two or three operated for various purposes is also growing throughout the city, so that electric drive has become one of the recognized features of the town. To accomplish this result, which has been brought about within comparatively recent time, T. C. McReynolds, secretary-treasurer and manager, and P. H. Palmer, the company's engineer and lighting superintendent, have made a systematic study of local power requirements and are prepared to give each prospective customer a detailed statement as to just what improvements can be effected in his particular case by the substitution of motor drive in place of power applied through shafting, belting, etc.

The company's campaign has not stopped at factories, shops, stores or industrial establishments of any kind, but has been carried into the homes of the city. Electric lighting is now becoming general and more than one-half of the company's customers have electrical apparatus of one kind or another, including laundry irons, heaters and cooking utensils. If progress made along this line during the next few years is at all commensurate with present indications, it will mean an enormous increase in business; and the probability is that more will be done in this direction than the most sanguine would believe, for the results of such work multiply almost in geometric ratio.

G. J. Marott, who lives in Indianapolis, is president of the company; T. C. McReynolds, secretary, treasurer and manager; P. H. Palmer, engineer, and H. P. Martzolf, superintendent of transportation. To each of these officials must be given credit for far more than the average enterprise and foresight and also to those actively concerned in the operation of the system for downright hard work.

Dark Spots with Alternating-Current Moving-Picture Machines.

To the Editor of the Electrical Review:

I was rather interested in a short article on the subject of dark pictures from a moving-picture machine, and having recently seen and tried the Kennelly stroboscopic fork at Atlantic City I thought I would show the article to a fellow townsman who is very successful in this line of business, having four shows on the road.

Instead of being interested in the article he was more amused and showed, from his experience, such a thing was impossible. In the first place, the alternations in the current are 7,200 per minute, or 120 per second, while the pictures move before the arclight beam at the rate of not more than fifteen to twenty per second, so that coincidence between the two is impossible.

He also stated that the majority of moving-picture men know nothing about lenses, and that most of the trouble comes from improper arrangement, and also from focusing. One rather startling thing he showed me was that the current used on his arc was sometimes more than sixty amperes, in some cases going as high as eighty. He says it is necessary to run it up to this in order to get a perfectly white screen, his sometimes being thirty feet in diameter.

E. W. Stevenson, E. E.

Wilkes-Barre, Pa., September 17.

THE DISCOVERY AND DEVELOPMENT OF THE LAWS OF THERMODYNAMICS.[1]—I.

BY DUGALD CLERK.

At the middle of the last century the steam engine had attained to a high degree of perfection. Its development was, it is true, incomplete; but it had been successfully applied to all the great duties of the mine, the waterworks, the factory, the railway and the steamship. The engines were mechanically excellent; the fuel economy was good, and they were built in units of thousands of horse-power. Steam power, in fact, was revolutionizing the whole of the social and industrial conditions of the globe. Notwithstanding this great material and engineering success, the world was in complete darkness as to the connection between steam motive power and heat. It was seen that motive power of almost any magnitude could be obtained by the agency of heat; but how it was obtained, and how much power was connected with a given quantity of heat, was quite unknown. The fuel consumptions of existing engines were known, and certain modes of improving economy were evident, and engineers were busily engaged in testing these modes by the slow but sure methods of invention, design, construction and operation in practical work; but in this they had but little aid from pure science. The science of thermodynamics did not yet exist.

New light was dawning, however, which gradually illumined the whole world of pure science and engineering practice.

Men of the first rank in intellect—Newton, Cavendish, Rumford, Young and Davy—had long before expressed the opinion that heat was not material in its nature, but was a mode of motion; but their opinions, although to some extent supported by experiment, made little impression upon the scientific world, and in 1850 we still find the most distinguished physicists adhering to the "caloric" or material theory of heat.

The great change from the errors of the old theories to the truth of the new was due to the work of Joule, Thomson and Rankine in Great Britain, and of Carnot, Meyer, Clausius, Helmholtz and Hirn on the Continent. The story begins with the work of Carnot in 1824, who published in Paris in that year a pamphlet entitled "Reflections Upon the Motive Power of Heat." He was attracted by the problem of the steam engine and the air engine.

[1] Presidential address delivered to the Engineering Section of the British Association for the Advancement of Science, Dublin, September 3.

He saw that heat and motive power were connected in some manner, and he endeavored to settle in a quantitative way the limits of that connection by the invention of an ideal series of operations, by means of which the greatest conceivable amount of mechanical power may be obtained from a given quantity of heat under given circumstances. For the purpose of his demonstration he assumes only two things: (1) That if heat be added to any body under standard conditions of temperature, pressure and volume, and the body be carried through any series of mechanical processes, returning ultimately to the standard condition of temperature, pressure and volume, then the quantity of heat added to the body is the same as that which has been discharged from it; (2) no process can exist whereby a given mechanical energy can increase its own quantity. On these indisputable assumptions he bases his ideal cycle, which consists of four simple and easily imagined operations, occurring within a cylinder behind a piston, so arranged that during the cycle work can be done by the working fluid upon the piston, or work done by the piston on the working fluid.

First Operation—The given volume of the working fluid is to be imagined as confined at its highest temperature and pressure behind the piston, and heat is to be added to keep the temperature constant, while the fluid expands, moving the piston and doing work upon it.

Second Operation—The supply of heat is cut off, and the working fluid expands, also doing work on the piston, while its temperature falls to the lowest point and its volume increases to its maximum.

Third Operation—The piston returns, compressing the working fluid, but allowing the heat of compression to escape, so that the temperature remains during the operation at its lowest point.

Fourth Operation—The piston compresses the working fluid, without allowing any loss of heat, to such an extent that the temperature rises again to its highest point, and the working fluid exists at the end of this operation at the same volume, pressure and temperature as at the beginning.

This assumed series of operations would give a certain available work area, the indicated power of the engine, inasmuch as the work done by the working fluid would be greater than that done upon it. If, however, it be assumed that in all the operations the direction of motion of the piston be reversed, then compression without loss of heat would take place in the second operation; further compression, but with sufficient heat loss to keep temperature constant, would occur in the first operation; the fourth operation would follow with expansion, and the third operation would conclude also with expansion. The engine would be reversed by beginning with the second operation, moving the piston backward in the order second, first, fourth, third. Carnot shows that this reverse operation would be performed by exactly the same amount of work as was given out by the direct operation, and that an amount of heat would be returned at the higher temperature equal to that which was added in the first case.

An engine which fulfils these conditions, Carnot states, will give the greatest amount of work which can be obtained from a given quantity of heat falling through a given temperature range. And it is evident that this must be so, because, if we assume the existence of any engine under the same conditions giving a greater amount of work from the same heat, then that engine could drive a Carnot engine in the reverse direction in such proportion as to return to the higher temperature a greater amount of heat than it abstracted, and so mechanical energy could be obtained without any heat fall whatever. This marvelous demonstration is obviously independent of the nature of the working fluid; it applies equally to all working substances, whether solid, liquid or gaseous, whether the physical state changes or not. It at once gives a standard of the limit of mechanical power which could possibly be obtained from a given amount of heat and a given temperature fall.

The Carnot cycle operations, as here given, are applicable either to the material or to the dynamical theory of heat; but Carnot originally stated that the whole of the heat added in the first operation was to be discharged in the third. Under the material or caloric theory work was supposed to be done by the fact of fall in temperature. Naturally, as the heat was material, it could not be destroyed or changed into mechanical energy. The production of mechanical energy was supposed to be incidental to the fall of temperature, much in the same way as mechanical energy was produced by the fall of water level, and this analogy is used throughout Carnot's work of 1824.

Carnot thus succeeded in proposing a standard of efficiency which was applicable to any heat engine, whatever the working fluid and whatever the operative cycle. By his method a limit could be set, fixing the maximum of mechanical energy to be obtained from a given heat quantity and a given temperature range. To reduce this to numerical values it was necessary, however, to experiment on any one working fluid within the desired temperature range in order to determine the work area in its relation to heat quantity and temperature fall. Carnot's writings show that he intended to make such observations; and had he succeeded, thermodynamics would have become a science at an early date. Carnot's death, however, in 1832, at the sadly early age of thirty-six years, prevented this development.

The name of Sadi Carnot will always be remembered by mankind as the founder of one branch of the thermodynamics of the heat engine.

His work remained practically without notice for thirteen years after his death, when, fortunately, it attracted the attention of William Thomson during his attendance at the laboratory of Regnault in the year 1845. Thomson was then twenty-one years of age, and had already attained a considerable scientific reputation. He took up the study of Carnot's work with enthusiasm. He became professor of natural philosophy in the University of Glasgow in 1846, and in 1848 he read a paper before the Cambridge Philosophical Society: "On an Absolute Thermometric Scale Founded on Carnot's Theory of the Motive Power of Heat and Calculated from Regnault's Observations." Like Carnot, Thomson accepted the material or caloric theory of the nature of heat, although, like Carnot also, he had doubts as to its truth. Assuming its truth, however, he carried Carnot's reasoning much further, and deduced from the Carnot cycle a thermometric scale which was absolute in the sense that it defined the idea of temperature independently of the properties of any particular body.

It is very difficult to carry one's mind back to the material theory of heat, but it is necessary to do so in order to appreciate the rigid accuracy of the reasoning of both Carnot and Thomson; and it is especially desirable to do so in order to understand the great step made in this paper. According to the caloric theory, heat was supposed to be a subtle elastic fluid which permeated the pores of bodies and filled the interstices between the molecules of matter. The fundamental quality imagined of this caloric or heat fluid was that of indestructibility and uncreatability by any humanly controlled process. Bodies became warmer when caloric was added to them, and grew colder as it left them. Caloric, however, might be added to a body without heating it. In this case the heat was called "latent," and the state of the body changed from solid to liquid, or from liquid to vapor or gas.

Caloric, too, was required in greater quantities for some substances than others in order to warm the body equally. The capacity for caloric was thus greater in some bodies than in others.

If any particular body were heated without change of state, it was hotter—that is, its temperature rose when the quantity of caloric present was increased. It was not difficult to define equality of temperature. This was defined by a constant condition when brought into contact. But it was very difficult indeed to define temperature on any rational scale.

To the acute and brilliant intellect of William Thomson it became apparent that he had in the Carnot cycle a powerful instrument capable of widely general use, apart altogether from the theory of heat engines; and he here uses it in a most skilful way to give definiteness and universal application to the idea of temperature, as Professor Larmor states, "elevating the idea of temperature from a mere featureless record or comparison of thermometers into a general principle of physical nature."

Thomson accordingly defines equal differences of temperature in terms of the reversible or Carnot engine.

Equal temperature differences are to be differences between the temperatures of the source of heat and the refrigerator, when the proportion of work produced from a given quantity of heat is the same. Thermometers graduated in degrees calculated in this way could naturally be treated as instruments based on definite principles, independently of any properties of any particular material. The idea of temperature here was in rigid logical consistency with the caloric theory of heat, and it carried out completely the analogy between power derived from the same quantity of heat falling from a higher to a lower level, and resembling a fall of water in producing its effects. For equal quantities of caloric, as of water, temperature fall was regarded as similar to fall in space, and so an accurate idea of the nature of temperature difference is attained.

This definition, however, gave a scale greatly differing from that of mercurial, air and other thermometers, the degrees defined by it corresponding to larger and larger intervals on the air thermometer as temperature increases. Professor Tait pointed out also that on such a scale the temperature of a body totally deprived of heat is negative-infinite.

All these difficulties do not detract from the fundamental importance of the idea here enunciated for the first time: the idea of an absolute thermometric scale theoretically applicable to all bodies—solid, liquid and gaseous. On the caloric or material theory of heat, motive power is obtained during the letting down or fall from a higher to a lower level of a given quantity of heat. The quantity of heat does not alter in the process; it is only its relative level which alters. There is no reason, therefore, for mentally limiting the amount of mechanical energy obtainable from any given quantity of caloric, just as there is no reason for limiting the amount of mechanical energy to be mentally derived from a given weight. Any desired quantity of energy may be derived from a weight of, say, one pound, if it only be allowed to fall far enough, assuming gravity to be constant through the range.

The investigation of the work to be derived from a given quantity of heat at a given temperature is thus a matter of experiment, which can be settled by measurement of the properties of a few bodies.

Reasoning, it is conceived, in this way, Thomson follows up his absolute thermometric scale work with an investigation entitled "Carnot's Theory of the Motive Power of Heat," described in a paper read in 1849 before the Royal Society of Edinburgh, in which he calculates from Regnault's experiments on steam the power developed by a Carnot reversible engine when using one-centigrade heat unit; that is, the heat necessary to heat one pound of water through one degree centigrade for temperatures from one degree to 231 degrees centigrade, the temperature falling in the engine in each case to 0 degree centigrade.

In this paper he asks himself two questions: (1) What is the precise nature of the thermal agency by means of which mechanical effect is to be produced without effects of any other kind? and (2) How may the amount of the thermal agency necessary for performing a given quantity of work be estimated?

Using Regnault's values for the properties of steam, he calculates the lines of compression and expansion without heat loss, the lines of compression and expansion with heat flow at the lowest temperature, and heat addition at the highest temperature, and thus arrives at the work area per heat unit let down. He tabulates these results and shows that what he calls "Carnot's function" diminishes as temperature rises, using the ordinary centigrade scale. On the caloric theory the methods are rigidly logical and correct, but some inaccuracy is introduced by the necessity of that theory for the discharge of the same amount of heat at the third operation as is taken in on the first. The paper is of great interest, however, because it shows clearly how fully the distinguished author realizes the necessity for re-examining the standard ideas of the nature of heat. Two paragraphs make this very clear:

"7. Since the time when Carnot thus expressed himself the necessity of a most careful examination of the entire experimental basis of the theory of heat has become more and more urgent. Especially all those assumptions depending on the idea that heat is a substance, invariable in quantity, not convertible into any other element, and incapable of being generated by any physical agency; in fact, the acknowledged principles of latent heat would require to be tested by a most searching investigation before they ought to be admitted, as they usually have been, by almost every one who has been engaged on the subject, whether in combining the results of experimental research or in general theoretical investigations.

"8. The extremely important discoveries recently made by Mr. Joule, of Manchester, that heat is evolved in every part of a closed electric conductor moving in the neighborhood of a magnet, and that heat is generated by the friction of fluids in motion, seem to overturn the opinion commonly held that heat can not be generated, but only produced from a source where it has previously existed either in a sensible or in a latent condition. In the present state of science, however, no operation is known by which heat can be absorbed into a body without either elevating its temperature or becoming latent, and producing some alteration in its physical condition; and the fundamental axiom adopted by Carnot may be considered as still the most probable basis for an investigation of the motive power of heat, although this, and with it every other branch of the theory of heat, may ultimately require to be reconstructed upon another foundation when our experimental data are more complete. On this understanding, and to avoid a repetition of doubts, I shall refer to Carnot's fundamental principle, in all that follows, as if its truth were thoroughly established."

In these two paragraphs Thomson sums up the whole situation in 1849, and promises further investigation and further attempts to deduce the nature of the connection between heat and work.

Assume, then, the truth of the caloric theory of heat, as Thomson does in the 1849 paper; we have a complete theory of the heat engine, based on the Carnot cycle, accounting for efficiencies which vary with temperature differences, but requiring no definite mechanical equivalent of heat; nay, antagonistic to the existence of such an equivalent. The caloric theory, as has been pointed out, is quite consistent with the theoretical possibility of obtaining an indefinitely great amount of mechanical energy from any given quantity of heat, provided the letting down, or fall of level, be indefinitely great.

At the time we are discussing—1850—the bare conception of the idea of an absolute zero of temperature is one which is startling in its boldness, and it must have been difficult, indeed, then to imagine any definite line of proof which could be followed to establish the real existence of such a physical limit. We are so familiar with the existence of very high temperatures, vastly transcending the temperatures in which we personally exist, that we can hardly conceive a temperature limit on the ascending side—that is, we can hardly think of any given high temperature which could not, under quite conceivable circumstances, be exceeded. We know, for example, that any metal—say, platinum—may be melted if its temperature be sufficiently increased; that a further sufficient increase will convert the liquid metal to the gaseous state, and that the gaseous metal may be heated indefinitely while in that state. We know the behavior and properties of many substances at high temperatures, and are aware of the strong tendency of all chemical compounds, when highly heated, to split up into the elementary bodies composing them. All this we appreciate, but we find it difficult to see how a point of temperature could be reached when it could be said: This is a physical limiting point on the ascending scale; we may heat a substance up to this temperature, but it is impossible to conceive of any higher temperature. It is necessary here to distinguish between a conceivable limit to an ascending temperature and a practical limit under existing conditions. We may thus place limits, say, to the temperature of coal-gas and air explosions, or the temperatures possible from the electric arc; the limit with coal-gas and air depending on one set of conditions, and the electric arc upon another set, such as the vaporizing point of carbon, and so on. In the same way, at the middle of last century it would have been considered quite reasonable to suppose that human existence was carried on at an intermediate plane of temperature, and that temperatures might exist as low, relatively to our mean temperature, as our known furnace and combustion temperatures are high. At this time, no doubt, such an idea was quite a reasonable one.

No such limit could be proved, even by the aid of the Carnot cycle, reasoning on the material theory of heat. If we assume that heat is material, and that in some way temperature fall doing work resembles, as Carnot supposed, the fall of water doing work in passing from a higher to a lower level, then no absolute zero is possible, because the same quantity of heat is supposed to exist at the low as at the high temperature. On this theory nothing in the idea of temperature suggests a possible physical limit. On the material theory the notion of temperature is one to which it is exceedingly difficult to attach a precise meaning.

Thomson's promises of further investigation were fulfilled in 1850, in which year he definitely accepted the dynamical theory of heat, and finally abandoned the material. His conclusions are given in a memoir of the first importance, which was read before the Royal Society of Edinburgh in 1851. It was entitled "On the Dynamical Theory of Heat." Before dealing with it, however, it is desirable to consider the work of Joule and others on another side of thermodynamics.

Long before 1850 the equivalence of mechanical work and heat quantity had been accepted by many scientific men, and Rumford had, indeed, made measurements of a rough kind. It remained, however, for Joule experimentally to determine the mechanical equivalent in the most accurate manner, and place what is now known as the first law of thermodynamics upon the sure basis of absolute experimental determination. His first paper was read before the Cork meeting of the British Association in 1843, and at the Oxford meeting in 1847 he read another, "On the Mechanical Equivalent of Heat," describing the results of experiments with paddles rotating in liquids driven by falling weights. By these years of work he had absolutely demonstrated the equivalence of heat quantity and mechanical work, so that no loophole of escape seemed possible; it appeared as if the material theory was rendered intellectually impossible to the trained intellect. This was not the fact, however, as is evident from both Joule's and Thomson's accounts of that British Association meeting.

Joule's earlier paper had been coolly received. Indeed, it is evident that the idea of a mechanical equivalent of heat was still distasteful to the physicists of the day, and its discussion was looked upon with dislike. Joule, at the 1847 meeting, addressed a small audience, and the account of his experiments was received without enthusiasm. This adverse atmosphere, so discouraging to the investigator, was quickly removed, however, when a young man rose to make his remarks and, by his enthusiastic comment and clear reasoning, at once succeeded in attracting the interest of those present. This young man was William Thomson, Professor of Natural Philosophy in the University of Glasgow. Speaking of this, his first meeting with Joule, at Manchester forty-six years later, Lord Kelvin said: "I can never forget the British Association at Oxford in the year 1847, when, in one of the sections, I heard a paper read by a very unassuming young man who betrayed no consciousness in his manner that he had a great idea to unfold. I was tremendously struck with the paper. I had first thought it could not be true because it was different from Carnot's theory, and immediately after the reading of the paper I had a few words of conversation with the author, James Joule, which was the beginning of our forty years' acquaintance and friendship. . . . I gained ideas which had never entered my mind before, and I thought I, too, suggested something worthy of Joule's consideration when I told him of Carnot's theory." This meeting was indeed fateful for the future of the science of thermodynamics, as it resulted in co-operation between two men of giant intellect, who between them performed most of the experimental work which was necessary to make thermodynamics an exact science. Their work alone sufficed to place the first and second laws of thermodynamics on the firm footing of accurate experiment and logical deduction.

Although Thomson was much struck by Joule's experiments, he did not accept the dynamical theory of heat at once. As he stated himself, "I had first thought that it could not be true because it was different from Carnot's theory."

Joule's discoveries at this date may be thus expressed:

Heat and mechanical energy are mutually convertible, and heat requires for its production, and produces by its disappearance, mechanical energy in the proportion of 1,390 foot-pounds for each centigrade heat unit, a heat unit being the amount of heat necessary to heat one pound of water through one degree centigrade.

Knowing, as Thomson did, that mechanical energy could be produced by the agency of heat, but that its amount varied with the temperature and temperature fall, Joule's discoveries seemed antagonistic to Carnot's demonstration; and, convinced as he was that Carnot's law was true, he naturally felt at first that there must be some other way of looking at Joule's discoveries seemed antagonistic himself.

Joule naturally believed in his own manner of looking at his results, and he apparently agreed with Thomson as to the antagonism between what may be here called the Carnot and Joule laws.

The material theory of heat might have been true; in which case there was no more need for any direct quantitative connection between heat quantity and mechanical energy than between the mass of a body and its mechanical energy. Any unit of mass may acquire any conceivable amount of mechanical energy if its velocity be great enough, and so any unit of heat on the caloric theory may produce any conceivable amount of mechanical energy if the temperature fall be great enough. Joule considered the Carnot law to be so inconsistent with his law that in one of his papers he proposes its abandonment as inconsistent with discovered facts. At this point the two ideas seem to be in opposition. The germ of reconciliation, however, is found in observations by Thomson in both the 1848 and 1849 papers. In paragraph eight, quoted here from the latter paper, it is stated:

"In the present state of science, however, no operation is known by which heat can be absorbed into a body without either elevating its temperature or becoming latent, and producing some alteration in its physical condition."

This is equivalent to saying that no case has been observed where heat disappears doing mechanical work. In a note occurring in the same paper he alludes to the fact that engineers always assume that the amount of heat found in the condenser of the steam engine was the same as that taken into the engine by the steam, in the following terms:

"So generally is Carnot's principle tacitly admitted as an axiom that its application in this case has never, so far as I am aware, been questioned by practical engineers."

This was quite accurate. Hirn's demonstrations that heat disappears in a steam engine when work is done were not made until 1857, eight years later.

In the 1848 paper he states:

"The experiments of Mr. Joule, of Manchester, seem to indicate an actual conversion of mechanical effect into caloric. No experiment, however, is adduced in which the converse operation is exhibited; but it must be confessed that as yet much is involved in mystery with reference to these fundamental questions of natural philosophy."

Here we find Thomson's mind engaged —in 1848 and 1849—with the very matter requiring proof. Joule had proved the generation of heat by means of mechanical work; Thomson required the proof of the converse case—the disappearance of heat when mechanical work was done by the working fluid.

This proof was forthcoming in the results of experiments on the compression and expansion of air. Accordingly, we find the Carnot and Joule principles reconciled in Thomson's paper of 1851, and the important deduction made of an absolute zero of temperature —273 degrees on the centigrade scale. The introduction of the idea of the mechanical equivalent of heat leads at once to an absolute zero of temperature, and allows of the determination of this physical lower limit by the use of the Carnot cycle for investigating the efficiency of a perfect engine using any working fluid. Air was the working fluid actually investigated, and the determination of its properties at ordinary temperatures was a vitally important result of the co-operation of Thomson and Joule. Their experiments lasted for many years, and their rigorous investigation disclosed the fact that internal work was done in expanding a gas; in fact, that in a gas expanding isothermally doing work, part of the heat only disappeared in external work and part was absorbed in separating the molecules.

The Joule and Carnot laws are now known as the first and second laws of thermodynamics.

The second law, in modern form, may be thus stated:

Although heat and work are mutually convertible, and in definite and invariable proportions, yet no conceivable heat engine is able to convert all the heat given to it into work. Apart altogether from practical limitations, a certain portion of the heat must be passed from the hot body to the cold body in order that the remainder may assume the form of mechanical energy.

The proportion of the total heat convertible into mechanical energy depends on the absolute temperatures of the hot and cold bodies; it is unity minus the lower absolute temperature upon the upper absolute temperature.

It appears that during Thomson's struggle to reconcile the two apparently opposing laws, Clausius, who had seen the same difficulty, arrived independently at its solution and published a paper "On the Motive Power of Heat and the Laws of Heat Which May Be Deduced Therefrom," at the Berlin Academy, in February, 1850. In this paper Clausius discusses Thomson's difficulties, and also arrives at the conclusion that the Carnot cycle may be reconciled to Joule's law by the omission of the supposition that during the third process the same amount of heat is discharged from the cool body as was taken in from the hot one. He states:

"On a nearer view of the case we find that the new theories were opposed, not to the real fundamental principle of Carnot, but to the addition that no heat is loss. For it is quite possible that in the production of work both may take place at the same time: a certain portion of heat may be consumed, and a further portion transmitted from a warm body to a cold one; and both portions may stand in a certain definite relation to the quantity of work produced. This will be made plainer as we proceed; and it will be, moreover, shown that the inference to be drawn from both assumptions may not only exist together, but that they may mutually support each other."

In his 1851 paper Thomson gives Clausius full credit for solving the difficulty between the Carnot and the Joule principles. Thomson gives Clausius the full credit for priority, but states that he was working on the same problem, and had arrived at the same solution in the year 1850, before he had seen Clausius's work. Clausius, however, assumed the theory of a permanent gas, which required the absence of internal work, but Thomson was not prepared to assume this without experiment. This determination rigidly to prove every necessary assumption, and his clear conception of the points necessary for proof, led to the extensive series of researches undertaken by Thomson and Joule with the object of determining how much gas thermometers differ from an absolute scale as determined by the combination of the Joule and Carnot laws.

(To be continued.)

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

ELMIRA WATER, LIGHT AND RAILROAD COMPANY.

The earnings of the railroad department of the Elmira Water, Light and Railroad Company for the quarter ended June 30 shows gross of $58,117; expenses, $42,-222; net, $15,895; other income, $2,914; total income, $18,809; charges, $15,589; surplus, $3,220.

KANSAS CITY RAILWAY AND LIGHT COMPANY.

The report of the Kansas City Railway and Light Company for the fiscal year ended May 31 shows gross earnings of $6,070,116; operating expenses, $3,228,-170; net earnings, $2,841,946; other income, $105,680; total income, $2,947,626. This was $122,186 more than that for the fiscal year ended May 31, 1907. The balance available for dividends amounted to $853,132.

PHILADELPHIA RAPID TRANSIT COMPANY.

The annual meetings of the Union Traction Company and the Philadelphia Rapid Transit Company were held in Philadelphia on September 16. The directors of the Union Traction Company were re-elected and two new directors were elected to the board of the transit company.

The report of the Philadelphia Rapid Transit Company showed that the deficit for the last fiscal year is only $92,048.78. Receipts from all sources amounted to $18,557,502.86; cost of operation, licenses, taxes and fixed charges, $18,649,551.64. The deficit for the preceding fiscal year was $364,048.53.

A resolution was carried to increase the indebtedness of the company from nothing to $5,000,000. This loan is to be met with the unencumbered assets of the Union Traction Company as collateral, and includes valuable securities of the various underlying companies.

CUMBERLAND TELEPHONE AND TELEGRAPH COMPANY.

The report of the Cumberland Telephone and Telegraph Company for the month of August and eight months ended August 31 shows gross for August of $490,511; expenses, $287,636; August net, $201,875; interest and taxes, $37,-724; August surplus, $164,151. Eight months' gross, $4,046,583; expenses, $2,353,317; eight months' net, $1,693,-266; interest and taxes, $298,081; eight months' surplus, $1,395,185.

MONTREAL STREET RAILWAY COMPANY.

The report of the Montreal Street Railway Company for the month of August and eleven months ended August 31 shows August gross of $329,772; expenses, $164,262; August net, $165,510; charges, rentals, etc., $70,077; August surplus, $95,432. Eleven months' gross, $3,329,-059; expenses, $1,978,659; eleven months' net, $1,350,400; charges, rentals, etc., $586,966; eleven months' surplus, $764,-434.

AMERICAN RAILWAYS COMPANY.

The report of the American Railways Company for the year ended June 30 shows gross income of $2,927,436; receipts, income from stocks and bonds owned, $479,029; miscellaneous income, $17,728; total income, $498,757; total deductions, $171,645; net, $327,112, equal to 6.4 per cent on the $5,095,100 capital stock. The gross earnings of the subsidiary companies increased $59,280 over 1907, or 2.07 per cent. The total number of passengers carried was 68,762,586, an increase of 1,137,855. Stockholders were paid $305,706 in dividends, leaving a balance of $21,406 to be added to the surplus account. The American Railways Company controls the Bridgeton & Millville Traction Company, Bridgeton, N. J.; Springfield Railway Company, Springfield, Ohio; People's Railway Company, Dayton, Ohio; Altoona & Logan Valley Electric Railway Company, Altoona, Pa.; Chicago & Joliet Electric Railway Company; Chicago & Desplaines Valley Electric Railway Company, Joliet, Ill., and Scranton Railway Company, Scranton, Pa.

Steam Turbines in Power Stations.

Harry Webster, associate member of the Institution of Electrical Engineers of Great Britain, presents a summary in the *Electrical Review* (London), September 4, of facts and knowledge which he considers, from his experience, to be of the greatest importance. In operating steam turbines of the Parsons type the temperature of the steam should not exceed 550 degrees Fahrenheit. This will give all the usual advantages to be obtained by the use of superheat without danger in a well-constructed turbine. A good mercury pocket at the steam inlet to the turbine is essential, with a properly protected thermometer kept in continuously, so that the temperature of the steam can be noted at any moment. A sudden rise of temperature from any cause may do considerable mischief in a very short time. A precaution which can not be too carefully observed is the prevention of any solid matter coming over with the steam. Good lubrication is of the greatest importance, and can be achieved by using a good mineral oil, keeping all trace of water out of it. Water can only get into the oil at two or three places, and will generally be found to proceed either from the steam sealing devices at the ends of the turbine or from the water in the oil-cooling tank. This can easily be located by separating a small quantity of water from the oil and putting it through the standard soap test for hardness. Should it prove to be hard water, the fault should be looked for in the oil-cooling tank; but, if distilled, it must be proceeding from the sealing glands. There is every reason to expect a large demand for low-pressure or exhaust-steam turbines, as undoubtedly a great number of really modern and efficient reciprocating engines are in use at the present time, and it is often preferable to install a low-pressure turbine to take the exhaust from these, and thus utilize every available pound of steam rather than to scrap the engines. Some good examples of this combination are already installed and are giving excellent results, the working pressure of the steam being as low as one pound per square inch. Mr. Webber considers that the barometric condenser is of the greatest advantage in a steam-turbine installation, but the governing feature, when deciding upon the type of condenser, will be the quality of water available. A point which it is well to bear in mind with condensing plant for steam turbines is that, owing to the absence of oil, all iron and steel parts are liable to rusting. He has found that steel rings fitted to the buckets of air pumps rust quickly, although the bucket and barrel are bronze; whereas phosphor-bronze rings last indefinitely.

Georgia and Florida Independent Telephone Companies.

A convention of independent telephone companies from Florida and Georgia was held at Bainbridge, Ga., on September 11. The convention was largely attended, some 16,600 telephones being represented. A permanent organization was effected, with the following officers: President, Dr. J. G. Dean, Dawson, Ga.; secretary and treasurer, W. N. Drake, Pelham, Ga.; vice-president for Florida, Dr. W. L. Moor, Tallahassee; vice-president for Georgia, T. E. Gurr, Bainbridge.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Electrical Equipment of the Royal Mail Steamship Orcoma.

The Pacific Steam Navigation Company's new twin-screw steamship Orcoma, of 11,532 tons, is the newest and largest of the company's fleet. The electrical equipment marks an advance in steamship fitting-up. Accommodations have been provided for 250 first-class passengers, 200 second-class passengers and a large number of third-class passengers. The machinery consists of two sets of quadruple-expansion, four-crank engines having cylinders twenty-six inches, thirty-seven and one-half inches, fifty-three and one-half inches and seventy-six inches in diameter by fifty-four-inch stroke, with three double-ended and three single-ended boilers for a working pressure of 210 pounds per square inch. The electric generating plant consists of four sixty-five-kilowatt, 110-volt, continuous-current generators, direct-driven by high-speed engines. The ship's lighting comprises 1,500 sixteen-candle-power incandescent lamps, three arc lamps for cargo purposes, and one Admiralty type Morse code signaling lamp. One of the large whistles is controlled by an electrical apparatus which admits of its being operated by a small handle on the navigating bridge. It can, in addition, be switched on to a special clock in the wheel-house which blows the whistle automatically at intervals of every sixty seconds. The ventilating plant consists of two eight-horse-power Allen enclosed motors driving Sirocco fans for ventilating the stoke-holes; four enclosed motors driving fans for ventilating the galleys and lavatories, and sixteen fifty-four-inch ceiling fans for ventilating the dining saloons. Eighty-six nine-and-one-half-inch trunnion fans are installed in the first-class staterooms. The laundry installation is driven by a five-horse-power enclosed motor. A passenger elevator serving the four passenger decks is driven by an eight-horse-power enclosed Siemens motor. There is also an electrically operated hoist for raising provisions from the refrigerating chambers. The galleys and sculleries are equipped with eight motors for spit-turning, knife-grinding, potato-peeling, bread-kneading, boot-cleaning and dish-washing. There are also an electrically driven bacon-cutting contrivance, electrically heated radiators, ovens, hot plates and irons, and the barber shop is fitted up with electrically driven hair brushes and fans in connection with the hair-drying apparatus. A very complete system of electric bells keeps the principal officers in close touch by means of an intercommunicating telephone system.—*Abstracted from Electrical Engineering (London), September 3.*

An Electrical Farm at the Electrical Exposition in Marseilles.

A model electrical farm at the electrical exposition in Marseilles is described by J. A. Montpellier. There is great scarcity of labor in the agricultural districts of France on account of emigration to the cities, but it is here shown how electricity can be made to perform all the arduous work on the farm, thus replacing human labor and remedying the existing evil. The modernized farm, which covers a surface of 800 square metres, is one of the most interesting attractions at the exposition, all the buildings of a typical farm being faithfully reproduced. The dwelling is equipped electrically throughout; there is an electric cooking stove in the kitchen simpler than that in the modern villa; an electric pump supplies ozonized water; there is an electric bread-kneader and an electric oven in the bakery; the laundry is furnished with a special pump, electric wash machines and irons; in the winter an electric fan supplies heated air to all the rooms, and it may be used to supply air cooled by ice in the summer. In the yard are a centrifugal pump installed over a well and driven by a small motor; plows, thrashing machines, huskers, winnowers, etc.; everything in full operation. The wine-cellar equipment is remarkable. It has a wine pump, grape-picker, beater and press, all operated electrically. For the manufacture of olive oil special electrically driven machinery is provided, such as presses, crushers, pumps, filters, etc. In the poultry house there is a bone-crusher, herb-cutter, electric brooders and breeders. The cowhouse contains a carrot-cutter, grain-crusher, oil-cake mill, root-cutter, as well as special apparatus for milking the cows. The dairy is furnished with the most modern utensils, cream separators, beaters and churns, manufacturing butter and cheese in view of the public. A pump and ice-making machine complete the outfit. In the stable an electric straw-cutter has been installed and also electric shears for shearing sheep. Bad odors in stables need no longer exist. Their disinfection and sanitation are efficiently effected by ozonized air produced by a special ozonizer. A shop containing a forge with an electric blower, an electrically driven band-saw, grindstone and other tools completes the installation of the farm. The vegetable garden has also received attention, for by means of electricity intensified cultivation may be practiced, so that it will be possible to obtain in winter strawberries, tomatoes and other early vegetables.—*Translated and abstracted from L'Electricien (Paris), August 29.*

The Manufacture of Carbide of Calcium.

A short history of this industry in Europe is here given by E. Rosenthal. It is well known that the experiments of Moissan and Wilson gave birth to this industry. The simplicity of the method of obtaining carbide of calcium in an electric furnace, namely, the treatment of a given mixture of lime and coke by an electric arc, gave rise to the crisis in 1900. In France, where the patents of Bulier were upheld, those factories that had been equipped for the manufacture of carbide were obliged to utilize their water power in other ways. But gradually, in France as in other countries, the factories formed combinations and thus became stronger; the methods of operation were improved, and if in 1900 all the factories were in the same position technically, this is no longer the case to-day. Furthermore, the German and French markets are regulated by two selling syndicates, of which most of the factories are members. The purely economic evolution of the carbide industry is not dealt with, the author discussing in this article the technical methods and various furnaces. The first furnaces were of circular or square section with a very heavy sheet-iron wall, which was covered inside by a thick layer of compact carbide. A square carbon electrode (forty to sixty centimetres square and 1.8 to two metres long) was suspended inside of the furnace and connected by thin copper sheets to one of the poles of a generator or transformer, while the other pole was connected to the graphite crucible. The intermediate space was filled with the material to be treated, a mixture of lime and coke, which was transformed into carbide by the heat of the arc. The carbide was allowed to cool in the crucible and then removed in the shape of a cone. A typical installation of that time utilizing 800 horse-power contained eighteen furnaces, of which twelve were operated simultaneously. Each furnace consumed 2,000 to 2,500 amperes, and the operation lasted from two and one-half to three hours. The mass of carbide was allowed to cool for about one and one-half hours, and it took one-half hour to recharge the furnaces. To manufacture a ton of carbide required, at that time, about 750 kilogrammes of coke, 1,000 to 1,100 kilogrammes of lime, and the consumption of the electrode did not exceed thirty kilogrammes. To obtain good results it was necessary to use coke containing few cinders and lime containing neither phosphor nor sulphur. Besides this, it was of advantage to use the raw material in small pieces or pulverized, as its fusion is thereby hastened. The Compagnie Electrometallurgique patented in 1889 a type of furnace meeting these conditions. The method of allowing the carbide to cool in the furnace, which results in a great loss of heat and a rather low output, was soon followed by the continuous operation of a closed furnace. An American, L. H. Hartenstein, even obtained a patent on this process. The material to be treated surrounded the entire extremity of the movable electrode and covered the arc during the whole operation. At intervals varying from fifty minutes to two hours, according to the work and the type of furnace used, the carbide was made to flow off into ingot molds. In this manner the consumption of the electrodes and the cost of production in general were greatly reduced. The efforts of manufacturers were directed toward perfecting details of the furnace and all phases of the process. Instead of suspending the electrodes from clamps or bolts, clamps with water circulation were invented, which at the same time permitted the electrodes to descend in the measure that they were consumed, and thus only a part of the electrode was traversed by the current and exposed to the direct action of the furnace. The furnaces were made larger and of different forms. In 1900 a furnace with two suspended and movable electrodes was patented by the Société Metallurgique of Froges. This furnace was a double one with two arcs in series, the tension of which could be regulated. Gin and Leleux invented similar arrangements and applied them in their installations. In 1904 Keller took out a patent on a furnace having several fusion chambers with electrodes connected by channels to a common central crucible, where the fused masses accumulated. Morani proposed a furnace with inclined fixed electrodes placed opposite each other so as to form two walls, the distance between which could be varied. Between them was placed an auxiliary electrode not in the electric circuit and serving merely to allow the arc to pass between the fixed electrodes. He generalized this arrangement and applied it to furnaces operated by three-phase current. Finally, the Compagnie Continentale d'Electricite of Glaris and its manager, M. Lanhoffer, obtained a patent on a method of manufacturing calcium carbide that deserves special mention. In view of the two phases of the process that take place in the furnace—the phase of transformation proper and the phase of fusion—M. Lanhoffer utilizes the furnace with two electrodes and separates the two phases which succeed each other in the same furnace, but are simultaneous in two furnaces connected together. An arc is formed between the crucible and the electrode and the mixture filled in, which is transformed into carbide. This carbide accumulates in the crucible in the form of a pasty mass, with which the electrode is gradually brought in contact. The current then acquires a very great intensity and its voltage is reduced to the value necessitated by the resistance of the carbide and other parts of the circuit. In this manner the carbide is fused very rapidly and is allowed to flow off. The two furnaces being in series, the phase of reduced tension or fusion in one furnace may be made to coincide with the phase of high tension or transformation in the other furnace. It is only necessary to lower the electrode in one and raise it in the other; then the flowing off alternates in the two furnaces and the process is entirely continuous. These furnaces are now in use in a number of factories. The electrode consumption is only ten to twelve kilogrammes per ton of carbide, and the production seven to eight tons per 1,000 horse-power in twenty-four hours. L. H. Hartenstein has recently obtained a patent on a three-stage furnace, in which the calcination of the lime, the mixture of lime and coke, the treatment of the mixture by the arc and its transformation into carbide are effected at the same time.—*Translated and abstracted from La Lumière Électrique (Paris), August 29.*

Interpole Traction Motors.

Dick, Kerr & Company have developed a series of interpole motors particularly suitable for tramway systems where extensive use is made of electric braking, and in any circumstances where the duty is more than ordinarily heavy. In some cases the motors will stand as much as 100 per cent overload without injury. The field frame is made in the usual form, of two bowl-shaped castings of soft steel of high permeability, thereby securing the smallest possible weight. The two halves are fitted together with a carefully machined joint to insure a good magnetic circuit and to make the frame both watertight and dustproof. The lower part of the frame is hinged to the upper half, permitting the lower field coils to be easily inspected and cleaned. Each armature bearing box is contained in a separate solid casting independent of the motor frame altogether, being held in position in the main motor frame by a tongued and grooved joint and firmly fixed by studs. The armature can therefore be lowered with the bottom half for inspection, or can be retained in position in the top half, as may be desired. It can further be removed from the main shell with its bearing boxes complete if occasion requires it. The main pole-pieces are made up of laminated sheet-steel punchings riveted together, and are bolted to the inner surface of the frame. The pole-pieces are interchangeable. Special arrangements are made for supporting the main field coils, two flat steel springs, each capable of exerting a pressure of about 400 pounds, being inserted between the field coil and the shell. The coils are held in place by the pole shoes themselves and brass washers which cover the surface of the coil. The interpoles are of solid steel, situated symmetrically between the main poles, and fixed in position by rivets. The interpole field coils are clamped in position by independent screws. Especially good ventilation of the armature is secured by means of the fanning action of the connections between the armature coils and the commutator bars. These connections are made of thin, flat copper strips, which, when the armature rotates, act as fan vanes and draw a current of air through the motor. This artificially produced draft is so effective that it enables a motor to run fully twenty-five per cent cooler than would be possible otherwise.—*Abstracted from the Electrical Engineer (London), September 4.*

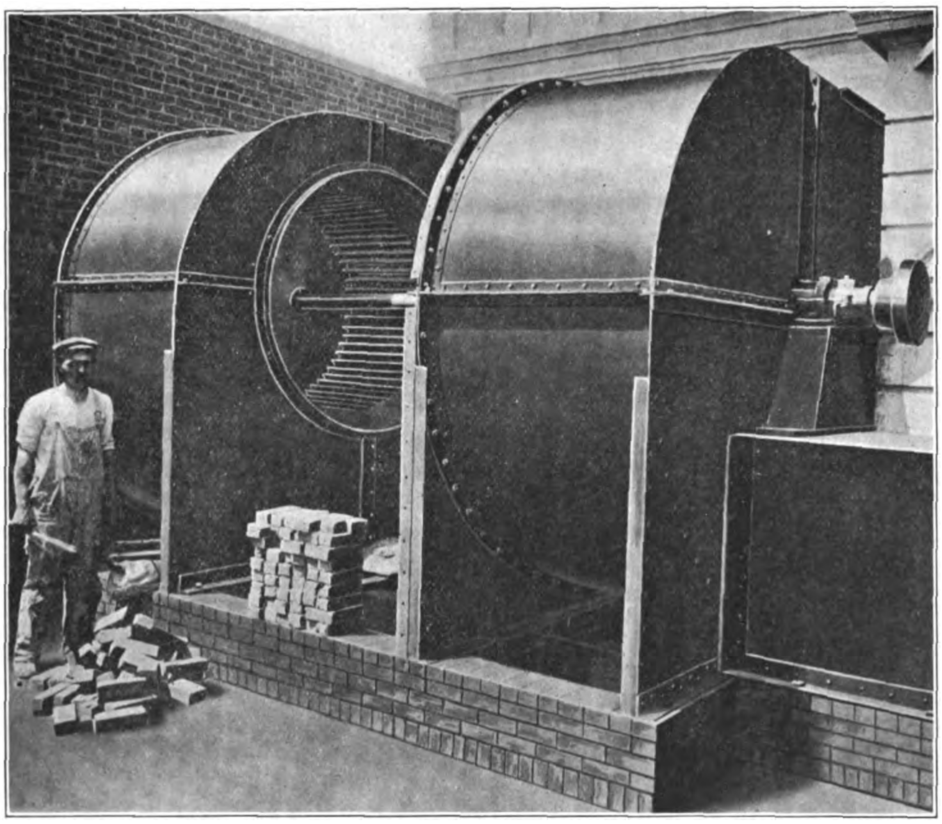
INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

A Notable Sirocco Fan Installation.

There has just been completed on the roof of the Hotel Astor a fan installation of so unusual a character as to make it of especial interest. The installation consists of two sixty-six-inch single-inlet Sirocco fans running on the same shaft. This shaft is fourteen feet between bearings.

The fans draw from a common intake chamber five feet eight and one-half inches wide. They are direct-connected to a thirty-five-horse-power motor. The capacity of the fans is 50,000 cubic feet of air per minute each, against a three-quarter-inch water gauge. The flue through which the fans exhaust is of brick. The photograph showing the principal features of the installation was made prior to the bricking up of the central intake.



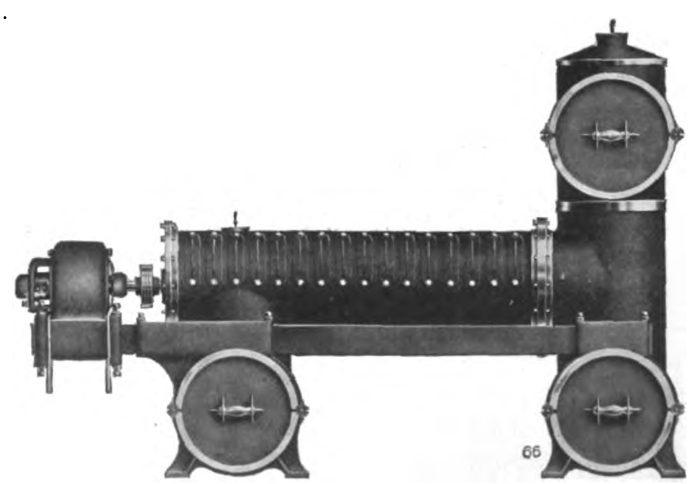
Sirocco Fan Installation on Roof of Hotel Astor, New York City.

The light weight and small size of the Sirocco fan for the heavy duty required made it possible to mount the fans on the same shaft, thus saving not only in cost of installation but in power. The power saving is said to amount to twenty-five per cent.

Electrical Cleaning.

What has been called a new science, the science of cleaning, owes its latest development and wide applicability to the electric motor. The suction method of cleaning is fast taking the place of the broom and dust-pan, which stir up the dust and allow most of it to resettle. Instead of this old-fashioned, semi-hygienic method, modern ingenuity has devised the scientific, yet simple, expedient of sucking in the dust and germs from floors, carpets, upholstery, or any other place where they may accumulate, and transferring them through tubes to a suitable receptacle, where they are collected in a condensed condition. In addition to its hygienic perfection, this method has the advantage that it is easy, and consequently cheap, to operate. The system consists of the cleaning tools, which resemble brushes; the flexible tubes and the exhausting machine, which contains the dust separator. The exhauster and dust separator can be conveniently located in the basement or cellar and connected by piping to inlets in the various rooms and halls, where the flexible connections can be made.

The fact that the exhaust collector requires power to drive it, at first limited the application of this principle to places which had convenient power plants, but with the electric motor its use has been greatly extended. At present, office buildings, theatres and residences are being extensively provided with exhaust cleaning outfits. The latest improvement in exhaust collectors has been made possible by the continuous rotary action of the electric motor. This is the application of the turbine principle to the exhauster. The accompanying view shows one of these turbine exhausters driven by a form L motor, built by the Crocker-Wheeler Company, Ampere, N. J. The turbine has only two bearings and, in addition, the automatic dust extractor is an integral part of the cleaner and no power is wasted in drawing the air through any screens or other retarding mediums before it passes



Electrically Driven Turbine Dust-Exhauster.

through the machine. When electrically driven the apparatus can not be disabled by freezing, as may be the case when the dust-laden air current has to pass through a humidifier or where the power is obtained from steam.

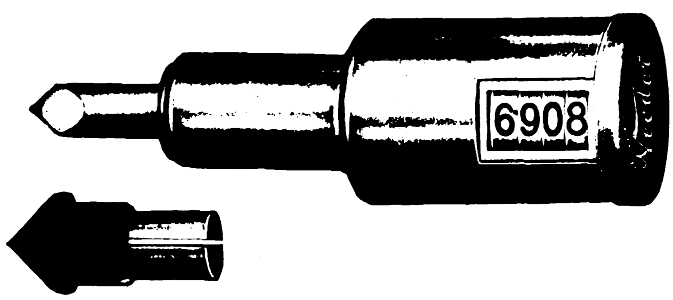
The cleaning tools used with this system have large orifices so that they will suck not only the dust but tacks, pins and scraps of paper as well.

The machine shown in the illustration is one of large size. The Crocker-Wheeler Company has been for some time supplying motors for exhausters of all sizes for use in various kinds and sizes of buildings.

Speed Counters.

The difficulty which has been encountered in obtaining accurately the number of revolutions of a generator or motor will be readily overcome by the use of a new speed counter put on the market by the Veeder Manufacturing Company, of Hartford, Ct. This instrument is shown very clearly in the accompanying illustration. It consists of a revolution counter which is operated through a clutch, the two jaws of this clutch being held apart by a helical spring when the counter is not in use.

The counter is used by placing its point against the shaft the speed of which is to be measured. So long as it is held with a light pressure, the clutch is out of engagement and the instrument does not register. A watch can be held in the other hand and at the beginning of a minute, by a slight pressure on its end, the counter is started registering. If the pressure is released at the end of a minute the counter instantly stops. The difference between the reading of the counter at the beginning and end of a minute is the revolutions per minute of the shaft.



Speed Counter with Insulated Tip.

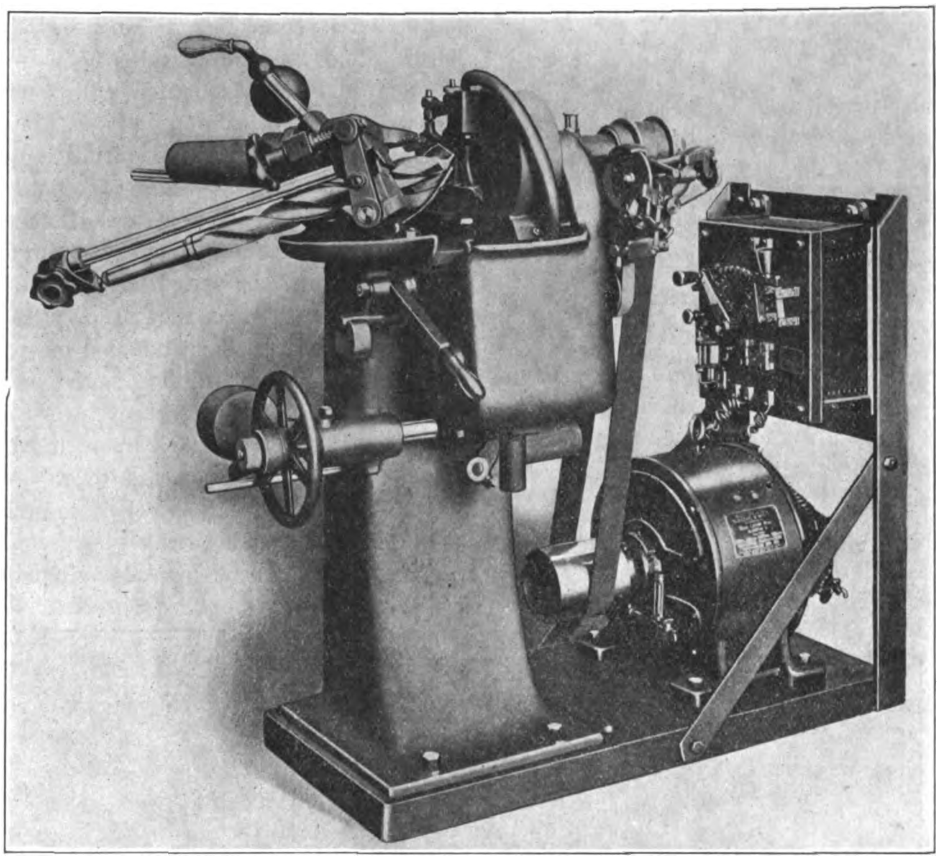
No arrangement is provided for setting the register back to zero; this operation taking more time than is necessary to set down the two readings of the counter and find the difference between them. The register is direct-reading, having all the figures in line; this prevents mistakes in reading the instrument.

This speed counter is peculiarly adapted to electrical work because it is not affected by magnetism and also because an insulating tip is provided which prevents any short-circuit through the instrument, and does away with the necessity of using a stop-watch.

Drill Grinding by Machinery.

It is a well-recognized fact that there is a theoretically correct shape for a drill, whether of the flat or twist type, in order to obtain the maximum amount of work from the drill. It is also fully admitted that hand grinding can not give this best shape and for this reason more power is required by the hand-ground drill than is necessary. In addition to this, a drill incorrectly ground will not bore a uniform hole to size.

Drills correctly ground and pointed will not only drill to size with minimum power, but when straight they will wear the drill press less than if incorrectly ground or out of true. In the latter case the force required to hold the drill steady brings a strain on the drill press which causes the bearings of the spindle to wear.



A Motor-Driven Sellers Drill Grinder.

The drill-grinding machine illustrated herewith is manufactured by William Sellers & Company, and is equipped with a standard Westinghouse motor of two-horse-power capacity. The entire outfit is self-contained with starting switch and motor complete. The grinder is suitable for any type of double-tip drills, varying from five-sixteenths inch to three inches in diameter.

The grinding of the tips is done on the face of the stone, or grinding wheel, which insures a correct surface as the drill is moved over the entire face of the wheel. By a special device the correct pointing of the drill is secured.

An interesting feature is the method adopted for providing an ample supply of water at the grinding surface. The wheel proper is protected by a cover at all points except where the drill comes in contact with it. On the cover there is an adjustable nozzle through which water is delivered in an abundant flow to both drill and wheel without splash or waste. The water is moved by a small centrifugal pump driven from the main motor.

The entire equipment is very simple, so that a skilled workman is not required; any man of ordinary care can operate the machine with perfect satisfaction.

The application of the motor to this grinder permits the machine to be located in the shop at any point desired, without reference to shafting or belts. It secures the maximum economy of driving power, inasmuch as the entire outfit may be stopped whenever not in actual use.

Milling Machine.

Many direct, as well as indirect, advantages resulting from driving machine tools by electric motors have resulted in a gradual improvement in the methods of attaching the motors.

In many instances the characteristics of the motors have been such that modifications could be made in the tools to such an extent that they were considerably simplified, as well as their productive capacity increased, by considering the motor and the tool as a unit in making the original designs. These applications may be contrasted with the somewhat older method of applying a motor to a standard belt-driven tool.

As direct and alternating-current motors have characteristics of a different nature the method of applying these two different types of motors is materially different. For that class of service requiring a variable cutting speed, the direct-current adjustable-speed motor is especially well adapted. A good example of this is shown in Fig. 1, where a fifty-horse-power Westinghouse motor is shown applied to a heavy milling machine manufactured by the Ingersoll Milling Machine Company. The motor has an initial speed variation of from 500 to 1,000 revolutions per minute, the speed being controlled by means of a drum-type controller not shown in the illustration, mounted at a point convenient to the operator.

In addition to the speed variation obtained in the motor, there are change gears, giving speed variations of about seven to thirty-five revolutions per minute, and the feed may be varied from one-half to fourteen inches, as may be required. The miller is particularly adapted to such heavy work as paneling locomotive side rods—which is perhaps as heavy work as such machines are called upon to do. The tool is powerful enough to remove forty-five cubic inches of steel per minute when taking a slabbing cut.

With the alternating-current equipment, as shown in Fig. 2, the speed of the motor is fixed and it is necessary to supply a suitable run of gearing, which may be operated by a lever to obtain the required changes in speed. As before, the speed range runs from seven to thirty-five revolutions per minute of the tool.

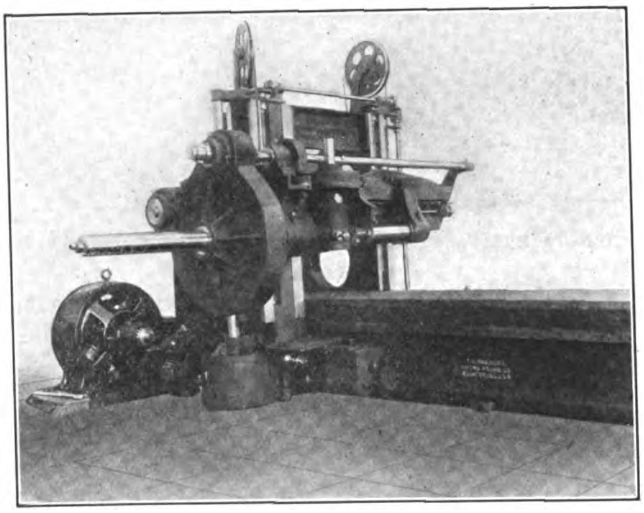


Fig. 1.—Milling Machine with Direct-Current Motor.

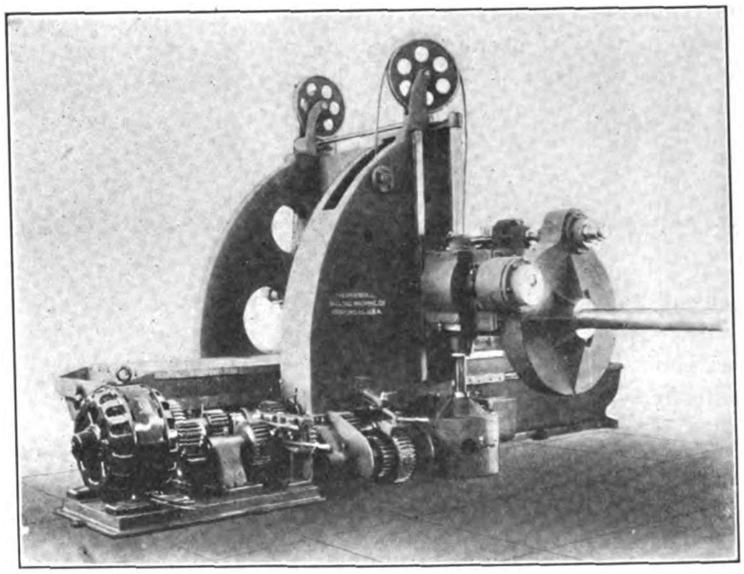

Fig. 2.—Milling Machine with Alternating-Current Motor and Gear.

Famatina Development Corporation.

The Famatina Development Corporation, which is interested in the development of copper mines near Chilecite, Argentine, is installing a hydroelectric plant, the generating equipment for which consists of two 200-kilowatt, 240-volt, revolving field generators with direct-connected exciters, together with a suitable switchboard and transformers for stepping the voltage up to 13,200 volts. The generators are belt connected to a line shaft driven by two four-foot Pelton water-wheels capable of developing 630 horse-power at 300 revolutions per minute. The head is 230 feet, the pipe line being 6,661 feet in length.

In addition to the generating station there are also two substations, one located at the smelter a short distance from the generating station and the other at the mines. The power in the smelter is taken direct at the generator voltage, while that in the mine is stepped down from 13,200 to 240 volts. In addition to the apparatus mentioned above, the General Electric Company also supplied several induction motors of various sizes for use both at the mines and at the smelter.

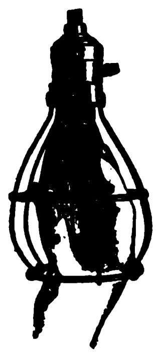
This installation is comparatively small, but is interesting from the fact that a twenty-mile transmission line will be erected from their generating station to the mines for transmitting only 100 horse-power (ultimately 200 horse-power), this comparatively large expenditure probably being due to the scarcity of fuel.

New German Cable Company.

The German-South American Telegraph Company has been founded in Berlin, Germany, with a capital of 4,000,000 marks. This capitalization will be increased from time to time as the business progresses. It has been stipulated that two-thirds of the board of directors must be of German nationality and must reside in Germany. The electrical manufacturing firm of Felten, Guilleaume & Lahmeyer, which originally obtained the concession and passed it on to the new company, will supply and lay down the new cable, and negotiations are under way with the Brazilian Government in regard to securing a landing place.

A Heavy Wire Lamp Guard.

The accompanying illustration shows a heavy wire lamp guard which has been placed on the market by Herbert T. Foster, of Worcester, Mass. This guard is firmly attached to the socket, and does not touch the lamp nor depend upon it



Heavy Wire Lamp Guard.

for support in any way. The same guard can be used with either a sixteen-candle-power or a thirty-two-candle-power lamp, and a lamp may be removed and a new one inserted without the guard being taken from the socket.

The advantages of this guard make it especially desirable for general factory and shop use, car-barns or any other place where a lamp is required to be protected.

A Thoroughly Insulated Incandescent Lamp Guard.

Quite recently there has been a good deal of prominence given to the possible danger which may exist if a metal lamp

Fibre Lamp Guard.

guard should become charged from a high-tension circuit through a defective cable or broken-down insulation, rendering the guard alive. A few weeks ago announcement was made of death by shock to a young man who had carelessly taken up a wire lamp guard which was afterward found to be defectively insulated.

The accompanying illustration shows a lamp guard made by the Benjamin Electric Manufacturing Company, Chicago, Ill., which, because of its construction and the material of which it is made, eliminates the possibility of injury from shock. The handle is made of well-seasoned and thoroughly insulated wood, and the guard proper is made of narrow strips of insulated fibre. The strips are placed radially to the lamp and cut off very little of the illumination from the light source.

First Annual Report, Public Service Commission, Second District, State of New York.

The first annual report, for the year 1907, of the Public Service Commission for the Second District, State of New York, has been issued. The commission took office and entered upon the discharge of the duties imposed upon it by law on July 1, 1907. The Second District commission has jurisdiction over all the counties of New York state except New York, Kings, Queens and Richmond. There have been created six separate divisions of the commission, as follows: Division of Light, Heat and Power; Division of Railroad Engineering and Inspection; Division of Statistics and Accounts; Division of Traffic; Division of Tariffs; General Office.

The work assigned to the Division of Light, Heat and Power is the supervision of all gas corporations, electrical corporations, the inspection and testing of gas and inspection and testing of gas meters, the inspection and testing of electric meters, the supervision of municipal electric plants, so far as power is given to the commission.

The Division of Railroad Engineering and Inspection includes the inspection and supervision of the physical properties of both steam and electric railroads.

This report covers the period for the six months ended December 31, 1907. On that date there were seventy-one electric railroads operating in the second district. These roads owned and operated 1,510 miles of track and leased or controlled 159 miles. There were 171 electrical companies and fifty corporations supplying both gas and electricity. For the inspection of electric meters the second district has been divided into four electric-meter inspection districts, with respective headquarters at Yonkers, Albany, Utica and Rochester. An inspector of electric meters, appointed from a list of eligibles furnished by the state Civil Service Commission, is stationed in each district, under the supervision of a chief inspector at Albany.

Vol. i of the report contains, in addition to the matter which is summarized below, appendices comprising the miscellaneous orders which have been issued by the commission during the period covered by the report. There is a general index and an index of the report of the Board of Railroad Commissioners. Vol. ii contains the abstracts of reports of corporations. It includes assets and liabilities, cost of road and equipment with distribution of cost, securities, funded debt, dividend-paying stock, non-dividend-paying corporations, road and equipment, miles of road operated, locomotives and cars in service, income with deductions and revenue from operation; operating expenses, distributed as to maintenance of way, etc.; freight operations, classification of commodities, passengers carried, monthly wages of employés, highway and railroad crossings and casualties of steam railroad corporations and electric railroad corporations, and gas and electrical companies. A supplement to the report comprises two magnificent maps showing in colors the steam railroads and the electric railroads operated in the state of New York.

The Kansas Gas, Water, Electric Light and Street Railway Association.

The eleventh annual meeting of the Kansas Gas, Water, Electric Light and Street Railway Association will be held at Pittsburg, Kan., October 8 and 9. Headquarters will be established at the Stilwell Hotel. The programme has been announced as follows: President's address, C. L. Brown, Abilene, Kan.; "Street Lighting—Arc and Series Tungsten," N. R. Birge, General Electric Company, Schenectady, N. Y.; "Electrical Jobbers," P. B. Chaney, Monarch Electric Company, Kansas City, Mo.; "The Correct Rate to Be Charged by Central Stations," W. A. Scothorn, Hutchinson, Kan.; "Commercial Insulation of Wire," F. H. Dimick, International Lecture Institute, New York, illustrated by lantern slides; "Finances of the Light Business," H. V. Forest, superintendent Winfield Electric Light Company; "Steam Turbines," C. R. Mackay, manager Toledo Railway and Light Company, Toledo, Ohio; "Incandescent Lamps," S. E. Doane, chief engineer National Electric Lamp Association, Cleveland, Ohio; "Our System of Bookkeeping and Records," Dow R. Guinn, Pittsburg Water Supply Company.

Current Electrical News

DOMESTIC AND EXPORT.

NEW WIRELESS TELEGRAPH COMPANY—Articles of incorporation have been issued to the Southern Wireless Telegraph Company, which is capitalized at $1,000,000, and which will have its headquarters at Little Rock, Ark. The company proposes to install a station and to place Little Rock in connection with eighteen other stations in Arkansas, Louisiana, Mississippi and Oklahoma. It is proposed to have the new station at Little Rock in operation in a short time and to locate the other stations as soon thereafter as possible. George A. Parker is president of the company, Harry C. Hale secretary and R. T. Balch treasurer.

WASHINGTON ELECTRIC ROAD INCORPORATED — The Spokane, Columbia & Western Railway Company is the name of the new electric and steam road which the Graves interests will build from Spokane into the Big Bend country. Articles of incorporation for the new railroad have been filed at the county courthouse, the capital stock being $3,000,000. Jay P. Graves's name does not appear as one of the incorporators. These are: Clyde M. Graves, Waldo G. Paine, W. G. Davidson, H. B. Ferris and Will G. Graves. All are connected with the Inland Empire system. The road will run from Spokane to the mouth of the Spokane River, seventy-five miles. Surveyors have been in the field for several weeks. Ample power will be available at the new power plant owned by the Graves interests at Nine Mile to operate the new line and the present lines of the Inland Empire system.

NORTHERN COLORADO POWER COMPANY TO ISSUE BONDS —The Northern Colorado Power Company has decided to increase its bond issue from $3,000,000 to $6,000,000, to provide money for proposed extensions to its transmission lines and to increase the capacity of its power plant at Lafayette. It was provided that the outstanding $3,000,000 be retired, and the present holders receive a like amount of the new bonds. The additional $3,000,000 in bonds will be utilized for construction work. Transmission lines will be extended from Greeley to Lafayette by way of Brighton. President Barker is planning to supply a large amount of power for irrigation purposes. There is, he says, a growing demand for electricity for pumping water on farms and the company is preparing to meet the demand. Scores of wells are being sunk on farms, and water will be pumped for irrigation.

NEW INCORPORATIONS.

ALBANY, N. Y.—Valatie Telephone Company. Valatie. $10,000. Incorporators: Edwin D. Howe, Wilson Miller, Valatie.

CHICAGO, ILL.—Traction Lighting Company. $100,000. Incorporators: Fred H. Atwood, Charles O. Loucks and Henry Tupper.

SPRINGFIELD, ILL.—Saline County Traction Company. $5,000. To build an electric line from Eldorado to Carriers Mills in Saline county.

SPRINGFIELD, ILL.—Roanoke Telephone Company, Roanoke. $2,000. Incorporators: P. W. Kennell, E. W. Rediger and J. J. Beer, Jr.

DOVER, DEL.—Safety Electric Railway Company. $50,000. Incorporators: A. H. Angle, A. Barbeel, Philadelphia, Pa.; W. I. N. Lefland, Dover.

BOISE, IDA.—Canyon Light, Power and Water Company, of Shoshone County. $250,000. Incorporators: Ellis L. Hale, W. R. Miller and L. C. Wilson.

NASHVILLE, TENN.—Great Falls Power Company, Davidson County. Amended charter, increasing the capital stock from $20,000 to $625,000.

AUGUSTA, ME.—Tuolumne River Power Company. $500,000. Officers: President, Charles D. Shaw, of Greenville; treasurer, William M. Shaw, of Greenville.

LOS ANGELES, CAL.—El Monte Home Telephone Company. $25,000. Incorporators: J. S. Killian, F. P. Sappington, Edgar O. Fawcett, I. Kauffman and A. F. Snell.

ALBANY, N. Y.—Westchester County Automatic Telephone Company. $100,000. Incorporators: Frederick Hughes, Helen Degnon, Joseph L. Abrahams, Yonkers, and others.

CLEVELAND, OHIO—International Independent Telephone Company. $10,000. Incorporators: C. Y. McVey, W. H. Hillhouse, J. C. Boush, W. H. Sheppard, W. E. Cary, Jr.

TRENTON, N. J.—Haytian Electric Company, Jersey City. $100,000. Incorporators: L. M. Arthur, S. H. Parsons and J. L. Egan. To generate electric current for heat, power and light.

BEEBE, ARK.—Beebe Light and Power Company. $10,000. Incorporators: J. S. Smith, president; M. Strickland, vice-president; E. Roberts, secretary and treasurer; G. H. Hills and F. D. Worthington.

GRAFTON, W. VA.—Oakdale Telephone Company, of Oakdale, Mercer County, W. Va. To construct and operate a telephone line. $1,000. Incorporators: J. R. Boyd and fifteen others of Mercer County.

DENVER, COL.—Naturita Valley Rural Telephone Company. $1,500. Incorporators: G. A. Akers, H. H. Ross, Henry Tamm, Roger L. Williams, George W. Hook, Arthur Priestley and K. B. Northrup.

OAKLAND, CAL.—Jahnke Aerial Telephone Company. $200,000. Directors: Albert Jahnke, John T. Geraty, Frank J. Golden, L. M. Sherwood, C. H. Halzborn, W. L. Harshbarger, W. R. Anderson and A. Kovanik.

JERSEY CITY, N. J.—The Billings Mutual Telephone Company, Jersey City. To operate public telephone exchanges and systems. $500,000. Incorporators: P. B. Moss, G. M. Hays, J. N. Perry, Billings, Mont.; S. S. Moore, Jersey City.

FORT SMITH, ARK.—Fort Smith-Oklahoma Light and Traction Company. $30,000. Formed for the purpose of owning and operating in Arkansas and Oklahoma, to deal in real estate, natural and artificial gas, etc. Incorporators: P. K. Reiss, I. S. Lowrey, E. H. Thomas, Rudolph Ney and C. P. Wilson. Mr. Reiss is president; Mr. Lowrey, vice-president; Mr. Thomas, secretary, and Mr. Ney, treasurer.

HARRISBURG, PA.—Kutztown Rural Telephone and Telegraph Company. $10,000. To operate in Berks and Lehigh counties, touching Kutztown, New Tripoli, Krumsville, Weaverville, Kingston, Steinsville, Wannamaker's, Lynnport, Roberts Corners, Werley's Corners, Sweitzer, Lynn Valley, Clausville, Guthsville, Maxatawney, Park Avenue and Monterey, all in Berks and Lehigh counties. Treasurer, Charles A. Stein, of Kutztown.

NEW MANUFACTURING COMPANIES.

NEW YORK, N. Y.—The International Wire Company, with a capital stock of $250,000, has been incorporated to act as contracting, mechanical and electrical engineer, and to manufacture cars, trucks, etc. The incorporators are A. A. Harrison, J. A. Walsh, Brooklyn; E. H. Cook, Wilkes-Barre, Pa.

ALBANY, N. Y.—The Nonpareil Electrical Manufacturing Company has been chartered with a capital of $50,000 to manufacture and deal in electrical supplies. The headquarters of the company will be in New York city. The incorporators are C. S. Shuman, A. F. Braatz, New York city, and E. M. Speer, New Jersey.

PERSONAL MENTION.

MR. E. H. BURLINGAME has resigned as manager of the Oelwein Light, Heat and Power Company, Oelwein, Iowa, to accept the position of superintendent of the People's Gas and Electric Company, of Chillicothe, Mo.

MR. J. H. CLUNE, Washington, Pa., has been appointed superintendent of the Butler division of the Bell Telephone Company, succeeding H. A. Trax. Mr. Trax has been transferred to the office of the general superintendent at Pittsburg.

MR. W. A. CATTELL, president of the Petaluma & Santa Rosa Railway Company, Petaluma, Cal., has tendered his resignation, to take effect October 1. He will be succeeded by E. M. Van Frank, general manager of the company. The pressure of private business was given as the reason for Mr. Cattell's retirement.

MR. GEORGE N. TIDD, general manager of the Scranton (Pa.) Electric Company has been made managing director of the Municipal Steam Heating Company, of Syracuse, N. Y. Both Scranton and Syracuse capital is interested in the company. This appointment will not interfere with Mr. Tidd's present connection.

MR. CUSTER L. FARNSWORTH, who for five years has been superintendent of the electric department of the Ludlow Manufacturing Company, Ludlow, Mass., has accepted the position of superintendent of construction with the Fitchburg (Mass.) Electric Lighting Company, and begins his work there October 1.

MR. C. E. F. AHLM, Cleveland, Ohio, has been retained as consulting engineer by the Board of Public Service of Lima, Ohio, in connection with the municipal electric lighting plant to be built in that city. The plant will consist of one 200-kilowatt and one 300-kilowatt units, 2,300-volt, sixty-cycle, three-phase, direct-connected to compound engines, and $80,000 has been appropriated for the work, which will begin at once.

MR. L. E. FISHER, of Danville, Ill., has tendered his resignation to President W. B. McKinley, of the Illinois Traction System, effective on January 1, 1909. Mr. Fisher will be succeeded as general manager of the McKinley system by H. E. Chubbuck, of Ottawa, Ill. Mr. Fisher entered the service of the Illinois Traction system in 1901, previous to which he had been superintendent for a short time of the electric light and power company at Paris, Ill. Mr. Fisher will engage in the railroad construction business.

MR. HENRY J. PIERCE, president of the International Railway Company, Buffalo, N. Y., announces that he will resign from the presidency of the company at the annual meeting on September 29, and that he will be succeeded by Thomas Penny, of the law firm of Norton, Penny & Sears. Mr. Pierce intends to devote all his time to the affairs of the Amsterdam corporation formed last May by himself and W. J. Wilgus, former vice-president of the New York Central & Hudson River Railroad Company. The company is engaged in the contracting and engineering business in New York.

MR. C. L. DE MURALT has been reappointed professor of electrical engineering at the University of Michigan for the coming year. During the winter season Professor Muralt will devote his attention to the consideration of the more general aspects of applied electricity. The course of lectures will include the discussion of: (1) The characteristics and application of alternating and continuous-current motors; (2) the design, construction and operation of electric plants; (3) the principles and methods of transmitting, distributing and controlling alternating currents; (4) the calculation and operation of electric railways, and (5) the management of electric properties, with special references to the commercial aspects of electrical engineering.

MR. GEORGE H. GUY, the well-known litterateur and secretary of the New York Electrical Society, is the author of a most interesting article entitled "Real Navigation of the Air," in the September issue of the *American Review of Reviews*. Mr. Guy has been a close student of the subject of ballooning and aeronautics for many years, and has enjoyed the friendship and confidence of the prominent aeronauts of the day. He is in possession of probably the finest collection of data on this subject, and his facile pen has turned to good account in this article the essential information which the world is so anxious at the present time to secure concerning navigation of the air. The article is not simply descriptive, as Mr. Guy draws upon his knowledge of the subject in interpolating a good deal of philosophy as to the possibilities of the future development of the science of aerial navigation.

OBITUARY NOTE.

MR. ALBERT P. SEYMOUR, for many years active in the firm of Pass & Seymour, Incorporated, manufacturers of electrical specialties at Solvay, N. Y., died last week at his residence in Monrovia, Cal. He retired from the business in 1906 on account of failing health, disposing largely of his interests, and had since resided in Monrovia. A year ago he went to Syracuse, N. Y., on a visit, and on October 5 was taken ill at the residence of J. Brewster Gere, where he was confined to his bed until about July 1 of this year. He then returned to California. Mr. Seymour was actively engaged in business in Syracuse for many years. He was connected for some time with the Electric Light and Power Company, now the Syracuse Lighting Company. Later he became a member of the firm of Pass & Seymour, which became Pass & Seymour, Incorporated. He is survived by Mrs. Emily Seymour, his widow; Albert P. Seymour, of Monrovia, his son; and Mrs. T. S. Johnson, his sister, and his sister-in-law, Mrs. A. H. Seymour, both of Syracuse.

TELEPHONE AND TELEGRAPH.

QUINCY, ILL.—Articles of incorporation have been filed for the Fall Creek and Payson Telephone Company, with headquarters at Fall Creek.

SANDY CREEK, N. Y.—H. C. White, who owns the Pillar Point telephone line, is arranging to give Dexter, Brownville and Watertown complete local lines with Watertown connections.

EMAUS, PA.—The town council has given permission to the Pennsylvania Telephone Company to build its line through the borough. The company is arranging for the extension of a line to Carbondale, the town council having granted the necessary franchise.

WILKES-BARRE, PA.—The Pennsylvania Telephone Company has awarded contracts for the necessary construction material in connection with the placing under ground of its wires in certain sections of the city, in accordance with an ordinance recently passed.

TREMONT, ILL.—The village board of Tremont has granted to the Farmers' Mutual Telephone Company a franchise to run its line though the village. The franchise runs for twenty years. The company is pushing the work of construction on the new line, which is being built south from Tremont.

DUBUQUE, IOWA—At the annual meetings of both the directors and the stockholders of the Interstate Telephone Company all the officers and directors were re-elected with the exception of Director J. J. Kahn, of Elkader, who was succeeded by George Kreibs, of Elkport. The officers and directors are as follows: President, J. M. Dunn, Earlville, Iowa; vice-president, R. W. Gadsen, Dyersville, Iowa; treasurer, C. M. Laxson, Earlville, Iowa; secretary, J. H. Denkhoff, Dyersville, Iowa. Directors: George Kreibs, Elkport; V. H. Stevens, Dubuque, and J. L. Paine, Fayette, Iowa.

HARTFORD, CT.—With the object of bringing about a general improvement in service conditions, the Southern New England Telephone Company has planned to place in effect, on October 1, in the cities of Bridgeport, Hartford, New Haven and Waterbury, certain adjustments of its residence rates which, it is believed, will lead to a more general adoption of single or individual lines by subscribers and thereby tend to eliminate the existing delays resulting from the large usage of party-line service. In substance, the company's plan contemplates the provision of single-line domestic service in these four cities at the rate of $36 per annum. This rate will be applied to those existing subscribers who are at present paying net charges of $40 per annum in Waterbury and $48 per annum in Bridgeport, Hartford and New Haven for a domestic single-line service and will be offered to new subscribers desiring such service. The two-party line service at present furnished in Bridgeport, Hartford and New Haven at the rate of $36 per annum will be discontinued, and the existing subscribers to domestic service at that rate will be provided with single lines at the same rate.

ELECTRIC LIGHTING.

DUNKIRK, N. Y.—The water board has awarded to the Westinghouse Company the contract for a twenty-five arc-lamp equipment.

ELLWOOD CITY, PA.—The Pennsylvania Power Company is to rebuild its plant which was destroyed by fire several months ago.

ROGERS, ARK.—W. R. Felker has sold his electric light and water plant at Rogers to W. S. Merkle, of St. Louis, who has taken charge of the plant and is now operating it.

BEAVER, PA.—The citizens of College Hill Borough have voted in favor of a $15,000 bond issue, the proceeds to be used to improve the town electric light plant.

FORT GIBSON, OKLA.—The Fort Gibson ice and electric light plant has been destroyed by fire. The origin of the fire is unknown. The loss will not exceed $20,000.

CARTHAGE, N. Y.—The village board of trustees of Carthage has signed a five-year contract with the Carthage Electric Light and Power Company to light the streets at $60 a light.

HAMILTON, OHIO—Lindenwald and East Hamilton, suburbs of Hamilton, are to be lighted electrically by the municipal lighting plant. The work of extension will cost about $20,000.

FLORESVILLE, TEX.—At a meeting of the city council F. Largen asked for a thirty-year franchise in consideration for which he proposed to construct an electric light plant in Floresville.

FAIRMONT, W. VA.—A new electric light company has been formed to be known as the Independent Power and Light Company. The officers are: L. C. Wyer, president; A. H. Donnelly, secretary.

BRISTOL, VA.—The Bristol Gas and Electric Company has closed a contract for new generators, turbine engines and other machinery aggregating $50,000 in cost, to be installed in its Bristol plant.

PARIS, ILL.—At a meeting of the city council an application for a thirty-year franchise was made by a company of local business and professional men, who wish to establish a plant for gas and electric lighting and hot-water heating.

LIMA, OHIO—Judge Mathers has made permanent the temporary injunction granted preventing members of the city council from reconsidering their action in passing the ordinance providing for an $80,000 municipal electric light plant.

SCRANTON, PA.—By a deal consummated recently, the Scranton Electric Company secures control of the Standard Electric Light, Heat and Power Company, of Avoca. The Scranton company now has a chain of light companies from Pittstown to Priceburg.

VIROQUA, WIS.—Having arranged with the city for an extension of its franchise, the Viroqua Electric Lighting Company will rebuild its plant and put in an entirely new service. The plant will be enlarged so as to meet the demands of the city for years to come.

KAUKAUNA, WIS.—The Kaukauna Gas, Electric Light and Power Company, which is composed of Milwaukee capitalists, has leased the new electric power plant just completed by the Green Bay & Mississippi Canal Company, with a capacity of 2,500 horse-power.

SALTILLO, MEX.—Important changes to the street lighting system of Saltillo are being made. The entire system has been rewired and larger and improved arc lights are being installed. The large, modern electric light plant has been completed and is ready for operation.

MONTGOMERY, ALA.—The Montgomery Light and Water Power Company announces that it intends to run an entirely new transmission line from Tallassee, Ala., thirty miles from this city, to Montgomery. The expenditures which the company has planned will amount to $100,000.

BUFFALO, N. Y.—The Cataract Power and Conduit Company has made application to the Public Service Commission at Albany for permission to issue $120,000 in gold bonds. The issue is desired to cover the purchase of additional lands and the extension and improvement of the power plant.

SALT LAKE CITY, UTAH—George H. Brumhall, representing a mining company in Utah County, has filed application for rights to the waters of Santaquin creek. It is proposed to withdraw twelve second feet of water from the creek to generate 1,200 horse-power for mining machinery and lighting purposes.

TURNERS FALLS, MASS.—At a meeting of the Turners Falls fire district it was voted to accept the report of the committee on street lights and the prudential committee was instructed to draw up a five-year contract with the Franklin Electric Light Company for seventy-six incandescent lights of sixty candle-power and sixteen arc lamps.

ONTARIO, ORE.—The Interstate Light and Water Company is running a line from its power plant at Horseshoe Bend on the Payette River to Weiser and from there it will be extended to the city. Aluminum wires are used in the construction of this line, which will later be connected with the Ox Bow Tunnel plant and the line extended to Boise. Six thousand volts will be transmitted.

NORWICH, CT.—In its annual report the gas and electric commissioners show that the department has made a profit of $26,986.15 during the year ended July 31. There was an income showing an excess over cost of production of $41,286.53. From this there had to be deducted five per cent for depreciation, leaving the net earnings as given above. This is an increase of $4,300 over last year and $7,000 over that of 1906.

BIRMINGHAM, ALA.—At a meeting of the directors of the Coosa River Electric Company it was decided to amend the charter of the company so as to enlarge the scope of the corporation. The company will begin to build a dam across the river in a short time and also to construct locks at the most suitable places along the river. The aim now is to supply electric power to all parts of the state in as short a time as possible.

WAPAKONETA, OHIO—The contract for the new municipal electric light plant at New Bremen, Ohio, was divided among three of the bidders. The Western Electric Company, of Columbus, was awarded the contract for furnishing the generator at its bid of $5,500; the St. Mary's Machine Company will furnish the gas engine, and the Westinghouse Electric and Manufacturing Company will supply the switchboard and connections.

NEW ORLEANS, LA.—Announcement is made of the awarding of contracts here and in Milwaukee, Wis., for the establishment of a complete electric lighting plant for Lucedale, Miss. Gregory M. Luce is to install the plant, which will furnish lights for his large mill interests there, as well as public-service lighting. It was stated that the contracts awarded reach fully $20,000. The Hollifield Electric Company, of Mobile, was awarded the contract for wires, insulation, poles, etc.

JERSEY CITY, N. J.—The board of aldermen, sitting as a committee of the whole, received a proposed ordinance that is intended to grant a twenty-year franchise to the Mutual Benefit Electric Light and Power Company to open the streets of this city and lay conduits therein for the supplying of electricity. The ordinance was drafted to meet the objections which prompted Mayor Wittpenn last June to veto an aldermanic grant to the company, of which James M. Seymour, Jr., of Newark, is president.

GADSDEN, ALA.—At a meeting of the city council the franchise asked for by the Etowah Light and Power Company, to allow it to enter this city with its wires for the sale and distribution of light and power, was granted, with some slight modifications. The company agrees to be ready to give service within eighteen months and puts up a forfeit of $2,000 in case of failure. No provision was made in the franchise for a lower rate of charges than now obtains. The present rate is sixteen cents per kilowatt-hour.

COAL CITY, IND.—Capitalists have closed a deal for the Steiner land, at Cataract, Owen County, on which the cataract falls of Eel River are located. The tract of land embraces both the upper and lower falls, for which the company paid $150,000. It also purchased 303 acres of land from Lowery Brown and Warren Meek, for which it paid $19,000, making the total purchase price $169,000. This gives the company possession of all the land between the two falls. A dam fifty feet high and estimated to cost $150,000 will be built just above the lower falls, which will create a reservoir between the two falls covering 600 acres. Power-houses will be erected at the lower falls and one of the greatest electric light plants in the state established. A traction line from Indianapolis will pass through Cloverdale and across the top of the dam and on to Brazil. It is said the proposed plant will be able to generate electricity enough to light every town in this part of the state.

BIDDEFORD, ME.—Active work has been begun by the Limerick Water and Electric Company, a subsidiary company of the Limerick mills, in the development of its water power at The Ledges, about three miles from Limerick village, and by January 1 it is hoped to have a power plant in operation there which will develop 600 horse-power, which will be sufficient to operate the mills of the company, and also furnish power for electric lights in Limerick village, and to operate an electric railway between Limerick and East Waterboro, the nearest railroad point.

YPSILANTI, MICH.—The city council has granted a thirty-year franchise to the Washtenaw Light and Power Company. General Manager Hemphill says that $60,000 will be expended in the construction of a plant and in the improvement of the Huron River. The ordinance provides that the needs of Ypsilanti shall be supplied with electricity developed within a radius of five miles of the city before power or light is supplied to outside cities. The rates are not to be above those in other cities of similar size. Construction will be begun this fall or early in the spring.

SALT LAKE CITY, UTAH—As a result of the purchase of its bonds by a syndicate of British capitalists, the Salt Lake Public Service Company has resumed work on the construction of its power plant in Cottonwood canyon after a shutdown of many months. J. J. Chambers, manager of the company, has severed his connection and all construction work will be under the direction of J. C. Hornung, resident engineer for the Schott Company of Chicago. It is expected application will be made to the council by the company for a renewal of the franchises to supply Salt Lake City with heat and lighting facilities. Most of the original franchises have expired since taken out.

SAN BERNARDINO, CAL.—The troubles involving the Metone Power Company, the Mountain Power Company and the Pacific Light and Power Company, which have occupied the attention of the local courts for the past four years, have been settled out of court, and notices of dismissal of action filed in the several cases. These suits were brought to settle the water rights of the various power companies in the canyon of the Santa Ana River east of this city and north of Redlands, and it is understood that a settlement was effected by reason of the sale of the property of the Mountain Power Company to the Edison Electric Company, which at the same time came to an agreement with the other companies involved. It is now announced that a large power plant will be installed as quickly as possible.

ASHEVILLE, N. C.—In the Federal Court Judge Pritchard appointed P. A. Wilcox as receiver of the Carolina Water, Light and Power Company, which has plants at Darlington and Marion, and of the Florence Light and Power Company, of Florence, all in South Carolina. Mr. Wilcox has also been named as receiver of the Rock Hill Water, Light and Power Company. Mr. Wilcox was appointed receiver of the Darlington, Marion and Florence plants on the bill in equity filed by the Real Estate Trust Company, of Philadelphia. In the case of the Carolina Water, Light and Power Company, the receiver was authorized to issue $30,000 in receiver's certificates to meet maturing obligations, and $20,000 of such certificates on account of the Florence Company. Mismanagement and financial inability to meet bond obligations are charged in each bill.

ELECTRICAL SECURITIES.

Since the bull movement was inaugurated last June there have been a good many prophesies as to its termination, and wonderment as to the real reasons underlying such a considerable improvement in prices. In many quarters it was held that the improvement was not justified by any inherent increase in values, but that it was stimulated for certain reasons by strong interests which had the market pretty well under control. Last week the reverse happened, and the sharpest break since the bull movement was inaugurated occurred, leading issues making losses extending from about four to ten points. While the break in this instance is held to be more or less due to an election scare, it is just as difficult to find any real reason for the demoralization as it was to estimate the reasons for the previous improvement. That the political situation is important no one will deny, but that it has changed materially in the last two months is difficult to prove. Trade conditions are making a slow and irregular improvement, but there is a better evidence of improvement now than there was two months ago. Money, it is true, is firm, but there appears to be an abundance of it ready for safe and sane investment. The crop outlook is certainly no worse than it has been, and it is to be expected that the decline of last week is merely a spasm, and will be checked very shortly, and things move again in a more satisfactory way.

Dividends have been declared upon the following electrical securities: Washington Water Power Company, of Spokane, Wash.; regular quarterly dividend of 1¾ per cent, payable October 1 to stock of record September 21. American Cities Railway and Light Company; regular quarterly dividend of 1½ per cent on the preferred stock, payable October 1 to stock of record September 21. Bangor (Pa.) Railway Electric Company; regular quarterly dividend of 1¼ per cent, payable October 1 to stock of record September 20. St. Joseph (Mo.) Railway, Light, Heat and Power Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable October 1 to stock of record September 15. Tri City Railway and Light Company; regular quarterly dividend of 1½ per cent, payable October 1 to stockholders of record September 23. Duluth Edison Electric Company; regular quarterly dividend of 1½ per cent on the preferred stock, payable October 1 to stock of record September 26. Providence Telephone Company; regular quarterly dividend of 2 per cent, payable October 1. American Telephone and Telegraph Company; regular quarterly dividend of 2 per cent, payable October 15 to stock of record September 30. Colorado Telephone Company; regular quarterly dividend of 1¾ per cent, payable October 15 to stock of record September 30. Bell Telephone Company of Canada; regular quarterly dividend of 2 per cent, payable October 15 to stock of record September 25. Canadian Westinghouse Company, Limited; quarterly dividend of 1½ per cent, payable October 1. General Electric Company; quarterly dividend of $2 per share, payable October 15. Butte Electric and Power Company; quarterly dividend of 1½ per cent, payable October 1. Massachusetts Lighting Companies; regular quarterly dividend of 1½ per cent, payable October 15. St. Joseph Railway, Heat, Light and Power Company; quarterly dividend of 1¼ per cent, payable October 1.

ELECTRIC RAILWAYS.

BURLINGAME, CAL.—H. W. Hagen, of San Mateo, has applied to the city council of this place for an electric railroad franchise to San Mateo beach.

ROCHESTER, N. Y.—The Rochester Railway and Light Company will reconstruct its storage battery plant at the station at the foot of Factory street at a cost of about $10,000.

MINEOLA, N. Y.—The board of supervisors has granted the New York & North Shore Traction Company the right to extend its trolley line from Mineola to Hicksville by way of Westbury.

SHEBOYGAN, WIS.—From the present progress of work on the Milwaukee and Fox River Valley Railroad it is expected that the line will be completed next spring. Grading operations will begin in a short time.

NEW YORK, N. Y.—The railway service of the Brooklyn Rapid Transit over the Williamsburg Bridge was opened on September 16 when Mayor McClellan drove a six-car "L" train from the Manhattan side to Brooklyn.

MERCERSBURG, PA.—It is stated that the Byrons, proprietors of the steam tanneries in Mercersburg and Williamsport, Md., are at the head of a company being formed to finance and build a trolley line connecting the two towns.

WEATHERFORD, TEX.—The survey for the Fort Worth, Weatherford & Mineral Wells interurban is completed to Millsap, eight miles from Mineral Wells, and the work of raising $250,000 subscription in the three cities has been begun.

DUBUQUE, IOWA—A gang of surveyors in the employ of the Clinton, Maquoketa and Dubuque Interurban Railroad Company is making surveys of the country between Dubuque and Maquoketa for the purpose of locating a route for proposed line.

DOYLESTOWN, PA.—Charles L. Baum and Samuel Crothers, Jr., have been appointed receivers for the Philadelphia, Bristol and Trenton Street Railway Company, which has defaulted in the payment of six months' interest on its $165,000 mortgage.

CHICAGO, ILL.—The Aurora, Elgin and Chicago Electric Railway will extend its line from Wheaton to Maple Park, Ill., where it will connect with its Clinton (Iowa) division, giving the railway company a direct line from Clinton, Iowa, to Chicago.

ROANOKE, VA.—J. W. Hancock, manager of the Roanoke Railway and Electric Company, announces that the contract for the company's new office building has been awarded to C. W. Hancock & Son, of Lynchburg. Work will be commenced immediately.

NEWARK, N. Y.—The village board has extended the franchise of the proposed Geneva, Phelps & Newark trolley line another year. On account of the recent business depression there was more delay than was expected in financing the road. It is stated that work will begin in the spring.

WALLA WALLA, WASH.—A franchise has been granted the Washington & Oregon Traction Company giving it the right to operate electric cars over the principal streets of the city for a period of twenty-five years. In consideration of this franchise the company agrees to pay the city $8,000.

CHEYENNE, WYO.—Work on the extension of the Cheyenne street railway system to Fort Russell, a distance of three miles, is to be begun at once, the War Department having authorized the railway company to use a right of way north of the main driveway connecting the city with the post.

ST. LOUIS, MO.—The Missouri Electric Railroad Company, a subsidiary of the United Railways Company, which recently took over the St. Charles & Western line, has filed its $1,000,000 bond mortgage to the Mercantile Trust Company as trustee in St. Louis. The bonds run for ten years at five per cent.

DES MOINES, IOWA—Articles of incorporation have been filed for the company proposing to build a railroad between Des Moines and Council Bluffs. It is capitalized at $30,000. The present officers are as follows: J. W. Russell, president; Frank M. Tompkins, vice-president; M. H. Miller, secretary; E. Lockwood, treasurer.

CONNELLSVILLE, PA.—The Manor Valley Street Railway Company has let the contract for the construction of a line from Irwin to Herminie to Ryan & Campbell, of Latrobe. Work will begin at once. The construction of the road alone will cost about $50,000. The Manor Valley Company is composed of Irwin and Manor capitalists.

IOWA CITY, IOWA—The city council has granted a franchise to Henry Negus, of this city, and I. J. Hamiel, of Tipton, for the construction of a street railway in Iowa City. Local capital is largely interested, and it is believed that the line will be constructed within two years. It is designed principally to serve the residents of the east and southeast portions of Iowa City.

COLUMBUS, OHIO—Stockholders of the Columbus Railway and Light Company at a meeting unanimously voted to ratify the lease of the properties of the Columbus Public Service Company, from the Columbus Light, Heat and Power Company, which was formed to take over the Public Service properties. The lease runs fifty years and includes all the franchises of the Public Service Company.

ST. LOUIS, MO.—Within two months surveys will be under way for the proposed electric railway to connect Mobile with Citronelle, Ala., thirty miles. Right of way has been secured. Over $500,000 will be spent. C. A. Elkins, of Louisville, Ky., and George S. Bressler, of Gulf Crest, Ala., are promoters of the project. The name of the line will be the Mobile & Gulf Interurban Electric.

LANSDOWNE, PA.—It is stated that the Philadelphia & West Chester Street Railway Company is negotiating for the purchase of the Chester & Darby division, and the Chester & Wilmington division of the Chester Traction Company, which belong to the Interstate Railways Company. It is said that the Philadelphia & West Chester Traction Company desires to extend its line to Wilmington.

ALBANY, N. Y.—Articles of incorporation have been filed in Albany by the promoters of the Greater New York Traction Company. The application for a charter sets forth that the company wants to build and operate an electric street railway in Fulton, Cortlandt and William streets and Maiden Lane, Manhattan Borough, connecting with the Brooklyn Bridge and ferries. The proposed rate of fare is three cents. The capital is $15,000, and the incorporators: C. F. Thum, Arthur G. Still, Joseph W. Spencer, Frank S. Burns, Charles M. Koop and others, of New York city.

YORK, PA.—It is stated that a new trolley line from York to Baltimore is to be built by York, Philadelphia and Maryland capitalists. The line has already been built from York to Hanover, and a survey will be made from that point. It is proposed that the cars connect with the Emory Grove line, which comes to this city, giving the people of York a route to Baltimore by trolley. It is said that a Philadelphia banking house will finance the scheme. Those interested are Captain W. H. Lanius and ex-Judge W. F. Bay Stewart, of York; H. W. Gitt and George Gitt, of Hanover; Dr. James H. Sherman, J. E. Mosenheimer, Jacob A. G. Frederick and Jacob N. Dehoff, of Carroll County.

DATES AHEAD.

American Institute of Mining Engineers. Annual meeting, Chattanooga, Tenn., October 1-3.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 5-6.

Empire State Gas and Electric Association. Annual meeting, New York city, October 7.

Kansas Gas, Water, Electric Light and Street Railway Association. Annual meeting, Pittsburg, Kan., October 8-9.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

Railway Signal Association. Annual meeting, Washington, D. C., October 13-15.

Order of the Rejuvenated Sons of Jove. Annual meeting, Buffalo, N. Y., October 15-16.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October 20-23.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Association of Car-Lighting Engineers. First annual meeting, Chicago, Ill., November 18.

INDUSTRIAL ITEMS.

THE TUNGSTOLIER COMPANY, 520 Citizens' Building, Cleveland, Ohio, is distributing a leaflet containing several testimonials from satisfied users of the Tungstolier system of lighting, bearing particularly upon the saving, the illumination, and the life secured with this system.

THE METROPOLITAN ELECTRICAL SUPPLY COMPANY, Chicago, Ill., is introducing a new insulating paint made by Frank S. DeRonde Company, of New York city. Mr. DeRonde was long connected with the Standard Paint Company. The company is also sending out a metal polish, made by the same company. It is claimed that the two articles have superior merit.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., has ready for distribution a new bargain list of motors. These motors are in packed St. Louis stock. They are second-hand motors only inasmuch as they have been in service. They have been cleaned up, refinished, repaired where necessary, and are sold at low prices with the same guarantee as is given on new machines.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., has secured an order from the Kobe Electric Railway Company, of Kobe, Japan, for two 500-kilowatt, twenty-five-cycle, engine-type, three-phase alternators; two twenty-kilowatt, 125-volt marine-type exciters; one forty-kilowatt motor-generator set; four forty-kilowatt transformers; 100 GE-78 railway motors complete, and a complete switchboard equipment for the power-house.

THE NEW YORK INSULATED WIRE COMPANY, 114-118 Liberty street, New York city, has published price list No. 22, entitled "Rubber-Covered Wires of Quality." This list gives prices on rubber-covered wires on the various copper bases, from eleven cents to twenty-one cents, besides containing various tables which will be found of considerable service. The booklet will be sent upon request to any one who uses or deals in rubber-covered wires.

THE BLAKE SIGNAL AND MANUFACTURING COMPANY, 246 Summer street, Boston, Mass., is constantly in receipt of testimonials to the excellence of its soldering flux. The following is a sample testimonial which has recently been received: "Enclosed please find twenty-five cents in stamps, for which please mail me as much Blake tube flux as this amount will pay for. I have used the sample tube you mailed me and it certainly is all that is claimed for it, and then some."

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, Pa., has closed a contract with the Chicago City Railway Company to furnish and install in the Plymouth Court substation a storage battery complete with booster, switchboard and wiring, rated at 4,800 amperes for one hour, it being permissible to discharge the battery at rates up to 9,600 amperes in emergency service. The battery is to be operated on a 550-volt bus. It will be charged at times of light load and discharged, as occasion may require, on the peak loads.

THE NATIONAL BATTERY COMPANY, Buffalo, N. Y., announces that the receivership under which the company has been operating since last February was terminated on August 19. The claims against the National Battery Company have been settled, and the entire property has been restored to the stockholders. It is also stated that the full control of the reorganized company has been secured by the Cutler-Hammer Manufacturing Company, of Milwaukee, Wis., well known as the maker of battery-charging rheostats and other electrical controlling devices. The plant of the National Battery Company will remain at Buffalo, but the business will be conducted under new management and with ample capital.

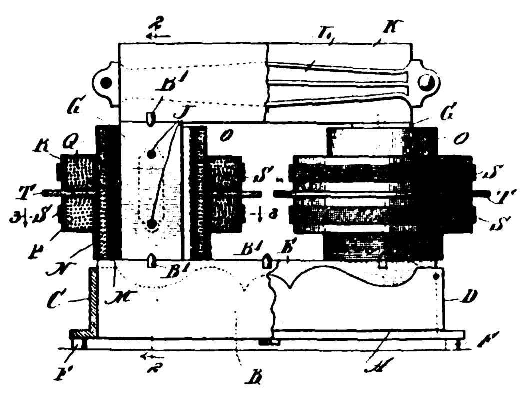
Record of Electrical Patents.

Week of September 15.

898,430. ELECTRICALLY CONDUCTIVE RAILWAY-RAIL JOINT OR CONNECTION. Bancroft G. Braine, New York, N. Y., assignor to the Rail Joint Company, New York, N. Y. Filed October 25, 1907. The railway is equipped with connecting plates contacting with the heads and base flanges.

898,473. RAILWAY SIGNAL. John Hoffer, Louisville, Ky. Filed January 14, 1908. Connections leading from the main switch to the signal operate an electric bell.

898,485. DEVICE TO PREVENT TROLLEY WHEELS FROM JUMPING. William O. Lane, Cleveland, Ohio. Filed December 20, 1907. The trolley pole is equipped with a forked bracket provided with a clamping plate.



898,529.—Electrical Laboratory Apparatus.

898,506. APPARATUS FOR THE PRODUCTION OF OZONE. John R. Quain, London, England, assignor of one-half to Edward Applegarth, London, England. Filed February 12, 1907. Means are provided for passing air through relatively narrow passages, the electrodes operating in vacuo.

898,509. ELECTRICAL-CIRCUIT PROTECTOR. Charles A. Rolfe, Adrian, Mich., assignor, by mesne assignments, to Rolfe Electric Company, Rochester, N. Y. Filed December 29, 1903. The contacts are normally under tension, and are held apart by a heat-concentrating device adapted to soften or melt the holding material.

898,529. ELECTRICAL LABORATORY APPARATUS. Chester H. Thordarson, Chicago, Ill. Filed April 17, 1905. A magnet-wound transformer for extremely high potentials.

898,540. ELECTRICAL FITTING. Edson B. Wilcox, Meriden, Ct. Filed May 29, 1908. An insulated electrical fitting.

898,544. TELEPHONE TRANSMITTER. Henry F. Albright, Elizabeth, N. J., assignor to Western Electric Company, Chicago, Ill. Filed October 28, 1907. The movable button is held in a bushing mounted in the diaphragm.

898,576. TELEPHONE SWITCH. Verne E. Green, Galva, Ill. Filed August 6, 1907. A common bus alternately connects a series of extension circuits.

898,578. ELECTRIC HEATER. Andrew J. Holmes, Tacoma, Wash. Filed May 10, 1906. An alternating-current coil heater.

898,607. ILLUMINATING APPARATUS. Jean Schmidt, Frankfort-on-the-Main, Germany. Filed May 8, 1907. A plurality of arcs is supported on translating members which have a common reciprocal movement.

898,619. TELEPHONE APPARATUS. Frank W. Wood, Newport News, Va., assignor to Charles Cory and John M. Cory, New York, N. Y. Filed April 17, 1907. A combination concentrically arranged mouthpiece and trumpet.

898,620. TELEPHONIC APPARATUS. Frank W. Wood, Newport News, Va., assignor to Charles Cory and John M. Cory, New York, N. Y. Filed April 5, 1907. A combination transmitter and receiver.

898,648. ELECTRIC CLOCK. Monnosuke Higuchi, New York, N. Y. Application filed November 3, 1903. Means are provided for rendering the alarm circuit inoperative.

898,649. ELECTRIC CLOCK. Monnosuke Higuchi, New York, N. Y. Filed November 3, 1903. Means are provided for selective ringing of the alarm.

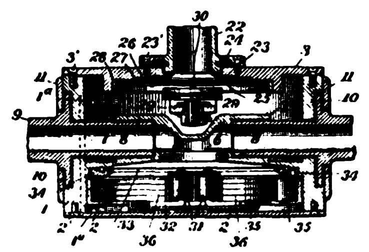
898,675. PASSENGER-RECORDING SYSTEM FOR TRAINS. Walter E. Parr, Sparta, Mo. Filed December 6, 1906. The system is designed to check the whole and half-fare passengers boarding the car.

898,686. ELECTRIC BELL. Tito Rosati, Florence, Italy, assignor of one-fourth to Ferdinand R. Sari and Bartolomeo G. Giuliana, Washington, D. C. Filed August 7, 1907. The bell is actuated by a high-potential circuit, and is put in operative condition by a low-potential circuit.

898,691. ELECTRIC-FURNACE PROCESS. George O. Seward and Franz von Kügelgen, Holcombs Rock, Va., assignors, by mesne assignments, to Electro Metallurgical Company, West Virginia. Filed February 21, 1906. New lengths of the electrode are successively fed to the charge without withdrawal of the electrode from the charge.

898,696. ELECTRIC LIGHT BULB CHANGER. Charles F. Southworth, Cambridge, Mass. Filed February 13, 1908. A combination of a rod and a cup having a continuous, elastic, annular rim.

898,698. FUSE BOX. John O. Stiners, Denver, Col. Filed October 26, 1906. A movable fuse carrier provided with pairs of contacts is mounted upon a contact plate.



898,620.—Telephonic Apparatus.

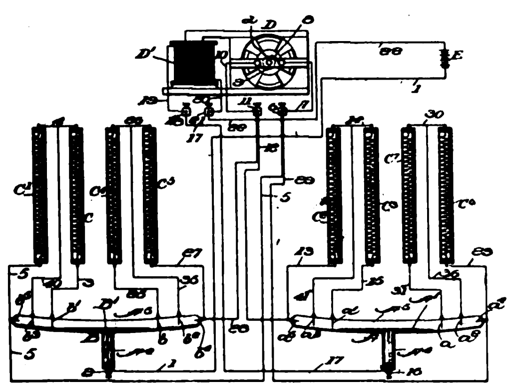
898,699. PORTABLE TELEPHONE APPARATUS. Frederick F. Strong, Boston, Mass. Filed April 3, 1905. A microphone arrangement with a flexible ear-piece.

898,715. INCANDESCENT LAMP. Frederick M. Bennett, New York, N. Y. Filed March 6, 1908. The filament is arranged to distribute the illumination in useful directions.

898,752. METAL FILAMENT FOR ELECTRIC INCANDESCENT LAMPS. Hans Kuzel, Baden, near Vienna, Austria-Hungary. Filed July 16, 1907. The stem is equipped with guide wires both at the end and at its middle position.

898,756. OUTLET BOX. George A. Lutz, New York, N. Y., assignor to American Circular Loom Company, Portland, Me. Filed January 5, 1907. The junction piece is provided with openings providing ringlike parts.

898,766. ELECTRIC SWITCH AND SYSTEM OF CONTROL. Joseph V. Mott, New York, N. Y. Filed February 2, 1907. A variable fluid resistance rheostat.



898,766.—Electric Switch and System of Control.

898,771. COMBINATION ELECTRIC-SERVICE CUTOUT AND METER PANEL. Henry E. McGowan and Edwin R. Ellsworth, New York, N. Y. Filed March 9, 1907. The measuring instrument and the cutout box are mounted on a single panel.

898,785. ELECTROLYTIC APPARATUS. Marcus Ruthenburg, Lockport, N. Y. Filed January 18, 1907. The outer tanks are sealed against the atmosphere and contain inner porous cups.

898,796. TELEPHONE SET. Sol S. Sonneborn, New York, N. Y. Filed October 1, 1907. The magnet receiver is mounted in the hollow stem of the desk set.

898,822. PLURAL LAMP SOCKET. Reuben B. Benjamin, Chicago, Ill., assignor to Benjamin Electric Manufacturing Company, Chicago, Ill. Filed February 23, 1907. A multiple socket equipped with a screw base.

898,823. PLURAL LAMP SOCKET. Reuben B. Benjamin, Chicago, Ill., assignor to Benjamin Electric Manufacturing Company, Chicago, Ill. Filed Feb. 27, 1907. The plug cluster has a central and an outer contact member.

898,824. PLURAL LAMP SOCKET. Reuben B. Benjamin, Chicago, Ill., assignor to Benjamin Electric Manufacturing Company, Chicago, Ill. Filed February 28, 1907. The plug is adapted to co-operate with a suitable socket, and carries a plurality of lamp-holding devices.

898,825. PLURAL LAMP SOCKET. Reuben B. Benjamin, Chicago, Ill., assignor to Benjamin Electric Manufacturing Company, Chicago, Ill. Filed March 1, 1907. The plural lamp socket is provided with a central contact and an outer contact adapted to co-operate with socket contacts.

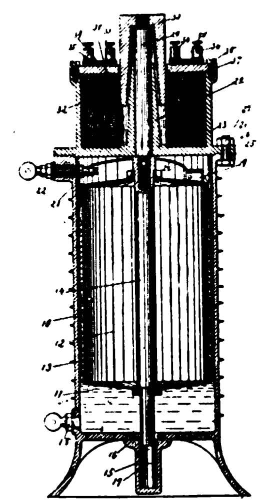
898,826. PLURAL LAMP SOCKET. Reuben B. Benjamin, Chicago, Ill., assignor to Benjamin Electric Manufacturing Company, Chicago, Ill. Filed March 1, 1907. A canopy cluster with a central contact and a side contact adapted to co-operate with a suitable socket.

898,847. APPARATUS FOR EXPLODING MINE CHARGES. Charles I. Dodson, Pittsburg, Kan. Filed April 6, 1907. The clock is provided with means for automatically operating a switch.

898,848. MEANS FOR EXPLODING BLAST CHARGES. Charles I. Dodson, Pittsburg, Kan. Filed February 14, 1908. A latch is provided for holding the actuating means in inactive position.

898,862. ELECTRIC RAILROAD SIGNAL. Timothy C. Fogarty, Frank W. Brock and Frank A. Bowdle, Chatham, Ill. Filed January 13, 1908. A rigid device is operated by the movement of the car, the movement of the semaphore closing a magnetic circuit.

898,888. SPARK-GAP. Isaac S. Hirsch, New York, N. Y., assignor to E. B. Meyrowitz, New York, N. Y. Filed July 18, 1907. Means are provided for varying the spark-gap.



898,987.—Rheostat.

898,915. ELECTRIC SIGNALING OR TELEGRAPH APPARATUS FOR USE ON VEHICLES. Robert B. North, Soho, England. Filed June 4, 1907. A plurality of plates is provided, each contact plate having a separate designation or order.

898,921. INSULATOR. Thomas F. Purves, Wandsworth, London, and John Sinnott, East Finchley, London, England. Filed February 3, 1908. The insulator is provided with a leading-in cavity, and the chamber may be sealed with insulating material.

898,949. ADVERTISING DEVICE. Charles T. Wilks, Woodlawn, Ala. Filed May 21, 1908. A combination of an electric lamp, a lamp circuit, and a series of rollers.

898,968. SIGNAL. David H. Coker, Piedmont, and Whitfield A. Scarbrough, Choccolocco, Ala. Filed January 23, 1907. The circuit is opened and closed by the operation of the railroad switch.

898,979. PROCESS OF ELECTRICALLY CONNECTING FILAMENTS TO SUPPLY WIRES IN ELECTRIC GLOW LAMPS. Hans Kuzel, Baden, near Vienna, Austria-Hungary. Application filed January 19, 1906. Finely powdered metals are melted to form carbides at high temperatures.

898,987. RHEOSTAT. Heinrich Poth, Brooklyn, N. Y. Filed December 8, 1905. An electromagnet is adapted to vary the active amount of the resistance medium in circuit.

898,992. ALARM. Jay A. Robinson, Denver, Col. Filed October 26, 1907. The receiver hook is held in its lowest position by an electromagnet.

899,012. ELECTRIC CLOCK. Monnosuke Higuchi, New York, N. Y. Application filed November 3, 1903. The hour and minute strikes are actuated by electromagnetic means.

WHITE LIGHTS FOR SHIPS AND LIGHTHOUSES.

In the current Quarterly of the United States Naval Institute, Dr. John Herbert Claiborne, of New York, announces a very interesting theory concerning a system of lighting ships and lighthouses in substitution for the ones at present in use. Dr. Claiborne is of the opinion that color blindness and partial color blindness are much more prevalent than we imagine, and although the rules for the detection of this optical defect have been brought to a high point of efficiency, still, scientific men are fallible, and so are the rules which they enunciate.

The ordinarily refractive eye perceives objects within a distance of about twenty feet by rays of light which are approximately parallel. When objects nearer than twenty feet are looked at it becomes necessary to add some power to the refractive media, in order to see distinctly, since the rays of light that come to the eye from objects within that distance are divergent. The accommodative muscle of the eye automatically contracts, and the crystalline lens, which is elastic and resilient in its nature, springs forward. In this manner a positive meniscus is added to the eye, its strength varying directly with the nearness of the object looked at.

The rate of vibration of the waves arriving from a distant point has a peculiar effect on this accommodative muscle. The greater the accommodative act, the nearer the object appears. The long waves, such as the red rays, require more effort, and hence red appears nearest, while the blue, which has the shortest wave length, and therefore requires the least accommodative effort, appears farthest away.

Dr. Claiborne suggests that white electric light be utilized for signal lighting of both ships and lighthouses. In order to avoid confusion as to the port and starboard points aboard ship, he would place a series of lights in some geometric formation, such as a parallelogram for the port, and a star for the starboard indications. For the alternate flashing arc for lighthouses, or the alternate-color disc scheme of indication, he would substitute white electric lights arranged in some such geometric formation as would provide through its shape and size definite information concerning its position relative to a danger point.

Dr. Claiborne's suggestions are, of course, interesting, as they indicate a possible direction in which the electric light may find a further field of usefulness. His suggestions concerning color blindness and the difficulty of detecting it are of importance, however, in connection with any system of signaling, at sea or on land, in which luminous color signals are involved.

CENTRAL STATION COMPETITION WITH GAS POWER.

One of the most difficult classes of installation for the central station to displace with electricity is the gas-engine plant operated from city mains at a cost of from eighty cents per thousand cubic feet downward. In some communities the local gas companies have made a strong campaign for isolated-plant installations supplied from their mains, and the well-known efficiency of power production at full load in the modern gas engine is undoubtedly a telling argument with the consumer. With no boiler plant or producers to occupy valuable space, with steam piping and coal handling out of the way, the gas company finds it comparatively easy in many cases to secure the business, and not a few central station solicitors have had to wait sometimes a year or two before the operating results with the gas installation opened the way toward consideration of the substitution of electrical service.

In the isolated gas plant, however, more than the usual skill is demanded from the operating engineers, in comparison with steam-driven installations, to secure anything like permanent economy of power production. The quality of the gas may be kept close to the standard purity and heating value, but the problems of proper ignition, valve setting, cleanliness of moving parts and surfaces inside the engines, lubrication and water cooling are always present. If the isolated-plant owner does not realize the importance of having the best operating skill in his engine room, and at a cost commensurate with the ability of the men needed to keep the equipment in the very best condition, excessive depreciation is sure to set in, with ever-increasing breakdowns. The number of isolated-plant owners who neglect the condition of their plants in this way is very large, and the central station man who can directly or indirectly obtain any idea of the frequency of shutdown in such a plant has a strong basis for action in trying to secure a hearing for electric service.

In a recent case of this kind a factory making printing machinery installed a gas-engine equipment consisting of a forty-horse-power engine supplied with city gas, and another of the same size operated by a producer located on the premises. The cost of the gas ranged from eighty to sixty-five cents per thousand cubic feet, depending upon consumption. Power was transmitted through numerous belts and line shafts to the machines on the different floors, and to run the factory both engines were needed constantly. It was found that the cost of operation was greatly increased above the expected figures by the frequent failure of the engines to supply the necessary capacity continuously, the expense for repairs being considerable, but less important than the time lost by the factory force when no machinery was in operation. The local central station installed a thirty-five-horse-power motor on one floor and a ten-horse-power motor on another in place of the engines, with the result that the total monthly power bill barely exceeded the old labor cost in the power plant plus repairs. The results of tests with the motors showed that the actual working load in the factory under the new conditions is but forty to forty-five horse-power, whereas with the engine installation both machines were hard pressed to meet the ordinary daily demands.

In another instance, where an isolated gas plant of some 600 horse-power was installed with engineering skill at the owner's command, the cost of repairs has been found to be so high that it is only a question of time when central station service will succeed in displacing the present gas installation. In one recent month the cost of repairs to the engines was $1,500, and while the average is somewhat lower than this, the figures are not encouraging from the isolated-plant standpoint. The fact that several engines were installed has made it possible to keep up a reasonably continuous service even in face of the repairs required. The simplicity of electrical supply from the local central station organization, and the resulting freedom from shutdowns and repairs, will doubtless create notable savings in operation when the new equipment can be installed. The experience of most central stations is that unless the small private gas plant is operated with unusual skill, its costs are bound to be high enough in time to justify the substitution of electricity.

THE TELEPHONE IN MOUNTAINEERING.

Announcement of the completion of the Mount Rosa telephone line—the highest circuit in Europe—illustrates a new phase of telephone activity which should ultimately be productive of the most far-reaching good. The growing interest in high-mountain climbing during the past few years calls for the best resources of science and industry for the successful ascents of peaks in the less widely known of the great ranges of the world. The Mount Rosa line will greatly facilitate communication between the Regina Margherita Meteorological Observatory, at an altitude of 14,958 feet, and all the important telephone centres of Europe. The first section, just completed, from the observatory to the Col de Lys (11,962 feet above sea level and some two and one-half miles long) presented exceptional difficulties. Owing to the high winds and severe storms prevailing in these altitudes an overhead line carried on poles was out of the question, and it was thought that an insulated cable laid in the ground would make repairs impossible by gradually sinking into the ice. At the suggestion of Dr. Alessandri, chief of the physical observatories of Mount Rosa, who had been carrying on experiments as to the insulating qualities of dry snow in these regions, it was decided to lay a bare wire across the snow fields and glaciers. The wire has been laid for more than six weeks with no damage reported, and transmission is clear and distinct. From the Col de Lys downward the line will be carried on poles short enough to enable it to touch the ground and avoid oscillations. When completed the line will connect three observatories, and it will greatly improve communication at times when the meteorological conditions are unfavorable for visual signaling. The line will also be useful for sending messages to the valley as to the state of the weather on the mountain, preventing tourists from risking their lives on bad days, and also facilitating assistance from below in case of accident or other difficulties.

THE ACCIDENT ON THE BERLIN ELEVATED RAILROAD.

On September 26 a severe accident occurred on the electric elevated road of Berlin, Germany, in which twenty passengers were killed and as many severely injured, one of the latter, in fact, subsequently dying; and a score receiving lighter injuries.

A train from Möckern Bridge station to Bülow Street station collided at the famous triangle with one coming from Leipsig Place station to Bülow Street station, throwing the first car of the last train completely off the structure, the second being partially held in suspension over the edge.

This triangle has been studied by many of the foremost engineers, and this scheme of operation has been adopted in many electric traction systems; for instance, one will find the same principle in the City Hall loop and above the Ninety-sixth street station of the New York city subway. It consists of a double-tracked triangle in which the trains do not cross each other's tracks. However, when two or more trains running in the same direction try to make a switch simultaneously there is danger of collision, which apparently was the cause of the recent disaster.

The six tracks of this triangle change their elevation in crossing above or beneath the different legs. Inside of the triangle is a car barn and above the latter structure is a signal tower.

This triangle, as well as the whole elevated road, is well equipped with an interlocking signal system. The operator in the tower can not give a signal for a clear track until a train has passed a certain section of the track.

The movements of the trains entering the triangle are controlled by a group of three levers, which is interlocked with the group controlling the outgoing trains, so that when a single train passes the triangle six levers have to be operated. To facilitate operation these levers are operated by alternating-current motors supplied by a motor-generator set fed from the third rail. The trains may be run under a headway of two and one-half minutes.

The trains are made up of three or six cars. Under ordinary conditions three cars are run, consisting of two third-class cars, with a seating capacity of thirty-nine each, and one second-class car, with a seating capacity of forty-four, placed in the middle of the train. The third-class cars only are used as smokers and these are also the motor-cars. It was the first car (third class) containing the motorman and his assistant, which was thrown off the structure, while the middle or second-class car was held partially suspended.

The cars are built after American patterns, the seats running lengthwise. The side doors, however, are not near the end, but some distance away, so that there are seats on both sides of the doors. Under ordinary conditions the end doors are not open for public passage.

The Berlin Elevated Road has been in operation since February 15, 1902, and has had hardly any accidents, particularly on the triangle. Considering the efficacy of the system, it is difficult to explain how such an accident happened. A rigid investigation will probably show the fault, which can not be seen on the surface. Immediately after the accident the Government sealed up the signal system and took charge of the situation.

DEPRECIATION IN MUNICIPAL LIGHTING PLANTS.

Failure to provide proper allowance for depreciation has been the cause of no little embarrassment to municipal electric light plants in this country. One of the latest stations under municipal ownership to illustrate the importance of depreciation is the plant at Wakefield, Mass., which is in need of some $50,000 if it is to be brought up to date as a producing installation. In accordance with the laws of Massachusetts requiring a depreciation allowance of about three per cent to be set aside annually in municipal plants, the Wakefield plant has made such a provision for the last three or four years. Such an allowance, however, has not been adequate to overcome the deterioration of the plant, which has been going on for many years without suitable provision to offset it. At the last town meeting, on September 24, a special committee appointed to investigate the lighting conditions in the town reported against any further municipal operation of the generating station after power can be secured from the Malden Electric Company. It is figured that the cost of central station power to the town will be only three and one-quarter cents per kilowatt-hour, against its own cost last year of 4.6 cents, and only a trifling investment will be necessary on the part of the town.

Until municipal plants learn to provide for something more than mere operating expenses from the earliest days of service, their costs are bound to throw them more and more into the hands of the central stations, who are generally far better equipped to render satisfactory service for the same expenditure. The private company progressively operated has enough business sagacity to foresee the inevitable wear and tear upon the plant, and provides for it by setting aside from each year's income enough money to keep the apparatus up to date. The average city experimenting with municipal ownership is anxious to get all it can out of its plant; the citizens expect lower cost of service than private corporations charge, and the force of public opinion is in the direction of rather free accounting, except in those states where close control by commission is the order of the day. It takes all the plant's income to meet these demands. A common fallacy is to figure that the street lights cost the city nothing under municipal ownership, since the rates for commercial lighting and power are made high enough to bear the burden. It is easy for the municipality to allow the plant to go to pieces when the income is inadequate to permit suitable renewals. The cost of apparatus, also, is as a rule higher in the municipal plant than in the private central station of similar capacity. The Boston *Herald* has said, in commenting upon the Wakefield case: "The characteristic failure to apply to the administration of public enterprises the principles which are essential to private business circumscribes the field of practicable and profitable public ownership and operation in this country."

DETERMINATION OF WIRELESS WAVE FRONTS.

BY GREENLEAF W. PICKARD.

It has been assumed, from theoretical considerations, that wireless communication would be affected by the vicinity of

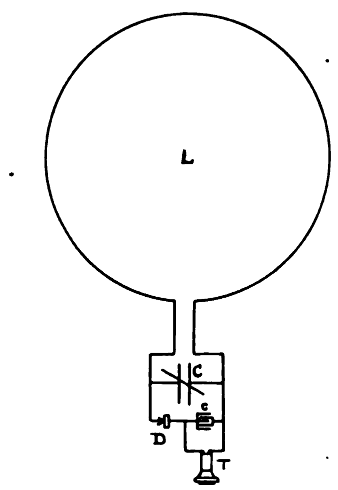

FIG. 1.—DIAGRAM OF CLOSED-CIRCUIT RECEIVING SYSTEM.

conducting structures, such as buildings, trees, etc. And it has been frequently observed in practice that a station in a city is not as effective as one on the seashore, where there are no energy-robbing obstacles in the path of the waves. It does not appear, however, that any one has determined just what the distortion

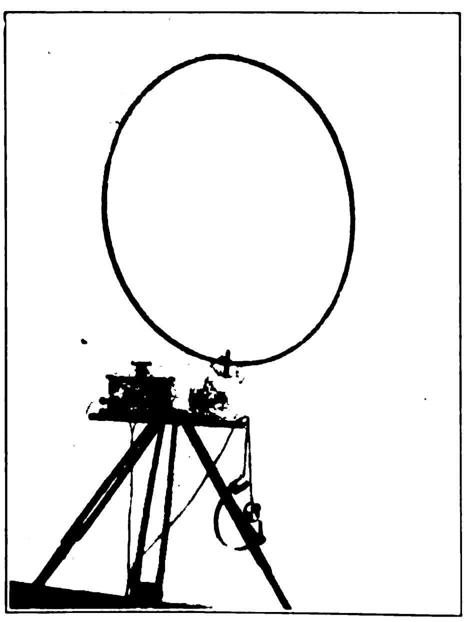

FIG. 2.—VIEW OF RECEIVING APPARATUS.

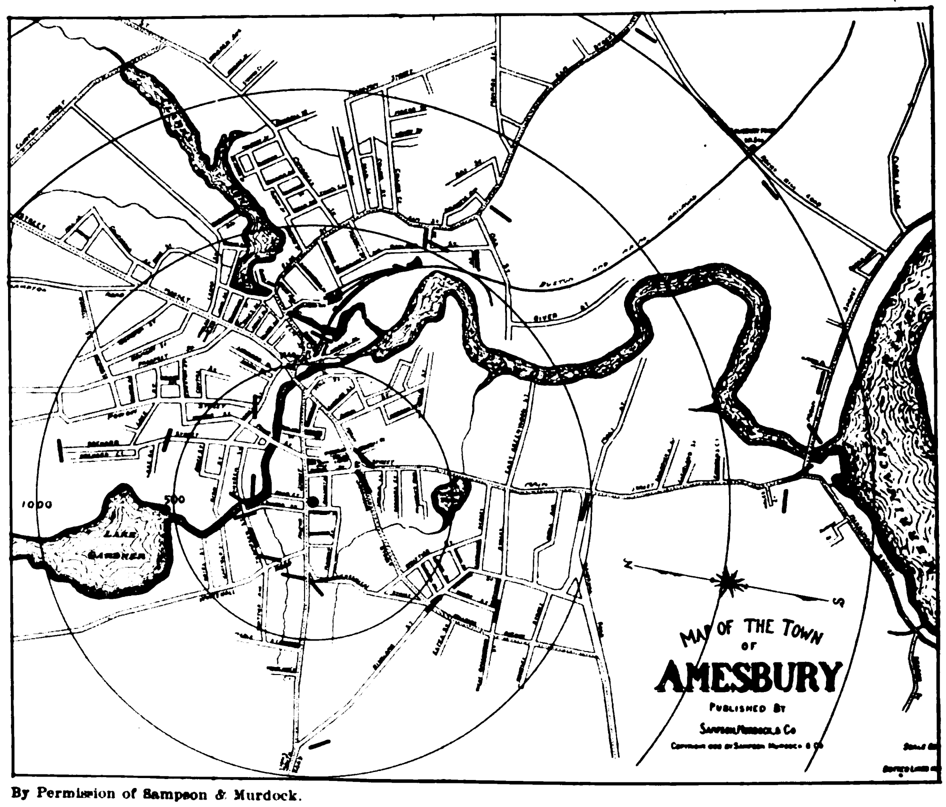
of the wave front really is, when this encounters buildings and other obstructions of a more or less conductive nature.

The writer has an experimental station in Amesbury, Mass., a town of about 10,000 inhabitants. As is usual in small towns, most of the buildings are wood, but there are many brick structures, the customary network of overhead wires, and a large number of shade trees, which might reasonably be expected to distort the waves used in wireless communication. Even a wooden house, transparent as the material may be to electrical waves, is usually lined with a system of well-grounded water and gas pipes, which gives the structure as a whole a conductive character. A series of wave-front determinations, made by means of the writer's underground receiving circuit,[1] showed clearly that such distortion existed and that the wave front in and about Amesbury was a very much warped surface indeed.

As determinations were only required at distances of a few wave lengths from the sending station, a very small closed circuit was employed, this being approximately one metre in diameter. This circuit consisted of three turns of No. 16 stranded copper wire, wound on a wooden hoop, its terminals being connected to a variable air condenser, and to a shunt circuit containing the writer's perikon[2] detector and a pair of high-resistance telephone receivers in multiple with a small fixed-value condenser. The circuit is shown diagrammatically in Fig. 1. It may be remarked that the use of three turns for the receiving circuit, in place of a single turn, is not for the purpose of gathering more energy from the waves, but merely to increase the inductance of the receiving circuit, in order that a conveniently small variable air condenser might be used for tuning.

For convenience in measurement and transportation, the entire apparatus was mounted on a tripod, the hoop being so mounted as to rotate freely on a vertical axis. The entire apparatus is shown in Fig. 2. Notwithstanding the small enclosed area of the circuit, it was found possible to receive intelligible signals at distances of over two miles from the sending station, and even to make determinations of wave-front direction.

The sending station was equipped with a three-wire aerial fan, 102 feet in height, connected by a simple autotransformer coupling with a closed oscillating circuit. In the closed oscillating circuit a glass condenser of 0.014 microfarad was used, charged to a potential of 20,000 volts. In all of the determinations the wave length used was 501 metres, and the power taken was 500 watts.



By Permission of Sampson & Murdock.

FIG. 3.—RESULT OF WIRELESS SURVEY.

The result of the wireless survey of Amesbury is shown in Fig. 3. For convenience in estimating distances, concentric circles have been drawn about the sending station, at intervals of 500 metres, or very closely, one wave length. At each

[1] "An Ungrounded, Closed Circuit for Receiving Wireless Signals," ELECTRICAL REVIEW, June 15, 1907. U. S. Patent No. 876,996.

[2] U. S. Patent No. 886,154.

determination point the apparatus was set up, and the hoop rotated until a null point was found, at which the sound of the sparks at the transmitting station ceased in the receiving telephones. As the closed circuit is actuated by the magnetic lines of force in the electrical wave, this null point is necessarily when the hoop is in the plane of the wave front, in which position it is not threaded by the magnetic lines. It was found easily possible to locate this null point to within a degree of arc. In Fig. 3 each position at which a determination was made is shown by a heavy short line, this line being the projection of the hoop on the map, or in other words a section of the wave front at that point.

Had there been no distortion of the wave front these short lines would in every case have been tangent to a circle

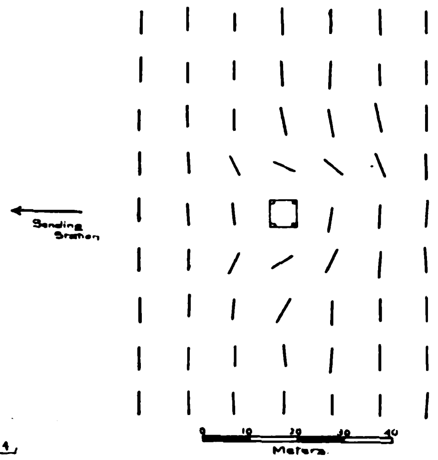


Fig. 4.—Wave-Front Determination, Showing Distortion in Vicinity of Obstructing Windmill Tower.

drawn through the point of observation on the sending station as a centre. While inspection of Fig. 3 will show several lines that are quite approximately so placed, it will at once be seen that the majority are by no means tangent; some, in fact, making angles of nearly ninety degrees with the theoretical undistorted wave front. As each such distorted portion of the wave means an eddy of lines of force around a conducting obstacle, with vertical electrical currents set up therein, it is evident that a considerable loss of energy is going on, to no other purpose than a slight heating of the obstacle.

Even such a high-resistance obstacle as a tree was found to make a perceptible eddy or indentation in the wave front,[1] while with a forty-foot steel windmill tower, distant some 1,500 metres from the sending station, a most marked distortion was found. This latter case was so interesting that the writer made a special study of the wave front in the vicinity of the tower, with the result shown in Fig. 4. It is hardly necessary to point out the resemblance to the well-known diagram of a current-carrying conductor in a magnetic field.

This simple method of mapping out the wave front in the vicinity of a wireless station is not only one of theoretical interest, but may have a practical application in determining, for example, why a station gives weak transmission in a certain direction. By the use of a larger closed circuit the survey could readily be extended to any desired distance from the sending station.

[1] In this connection it is interesting to note U. S. Patent No. 782,181, of G. O. Squier, for the use of trees as receiving antennæ

ILLUMINATING ENGINEERING SOCIETY.

SECOND ANNUAL CONVENTION TO BE HELD AT PHILADELPHIA, PA., OCTOBER 5 AND 6.

The second annual convention of the Illuminating Engineering Society will be held at Philadelphia, Pa., on Monday and Tuesday, October 5 and 6. The convention headquarters will be the Hotel Walton. Sessions will be held in the auditorium on the tenth floor of the hotel. An interesting exhibit of historical and scientific illuminating devices has been arranged adjacent to the convention room. Members will register at the assistant secretary's desk, convention floor, to obtain badges and cards for entertainment.

The following programme has been announced:

Monday, October 5, at 10.30 A. M.—Address of Welcome, Hon. John E. Reyburn, Mayor of Philadelphia. Presidential Address, Dr. Louis Bell—A study of the problem of street lighting in its broader aspects, especially with reference to the choice and placing of lamps in their relation to effective illumination. Report of Committee on Nomenclature and Standards, presented by Dr. A. C. Humphreys, president Stevens Institute.

On Monday, October 5, at 8 P. M., the following papers will be presented:

"Modern Gas Lighting Conveniences," by T. J. Little, Jr.

"Illuminating Value of Petroleum Oils," by Dr. A. H. Elliott.

"Street Lighting Fixtures: Gas and Electric," by H. Thurston Owens.

"Structural Difficulties in Installation Work," by James R. Strong.

"Architecture and Illumination," by Emile G. Perrott.

On Tuesday, October 6, at 9.30 A. M., the following papers will be presented:

"Intensity of Natural Illumination Throughout the Day," by Leonard J. Lewinson.

"The Integrating Sphere in Industrial Photometry," by Dr. Clayton H. Sharp and Preston S. Millar.

"The Ives Calorimeter in Illuminating Engineering," by Dr. Herbert E. Ives.

"Calculating and Comparing Lights from Various Sources," by Carl Hering.

"The Calculation of Illumination by the Flux of Light Method," by J. R. Cravath and V. R. Lansingh.

On Tuesday, October 6, at 2 P. M., these papers will be taken up:

"Street Lighting with Gas in Europe," by E. N. Wrightington.

"Design of the Illumination of the New York City Carnegie Libraries," by L. B. Marks.

"Engineering Problems in Illumination," by Alfred A. Wohlauer.

"Intrinsic Brightness of Lighting Sources," by J. E. Woodwell.

"Some Experiments on Reflection from Ceiling, Walls and Floor," by V. R. Lansingh and T. W. Rolph.

"The Relation Between Candle-Power and Voltage of Different Types of Incandescent Lamps," by Francis E. Cady.

Westinghouse Plan.

It was officially announced on September 28 that the bondholders' plan of reorganization of the Westinghouse Electric and Manufacturing Company, involving a foreclosure sale of the property, has been abandoned and in its place the so-called merchandise creditors' plan has been adopted.

It appears that the creditors' committee was unable to induce the stockholders to subscribe to the full quota of $6,000,000 of stock which was agreed upon last spring. There is, however, $4,500,000 of the new stock subscribed. The following official statement was issued recently by Joline, Larkin & Rathbone, counsel of the Jarvie committee, familiarly known as the Bondholders' Committee:

"The Readjustment Committee of the Westinghouse Electric and Manufacturing Company, of which James N. Jarvie is chairman, after a session lasting two days, adopted substantially the so-called merchandise creditors' plan, notwithstanding the fact that the cash subscriptions to the new assenting stock of $6,000,000 contemplated in such plan do not at this time exceed $4,500,000, and although the assent of a considerable amount of the bank debt and a portion of the merchandise debt still remains to be secured.

"This substitute or modified plan was adopted, however, with the distinct understanding that the plan will not be declared operative unless the full $6,000,000 of cash subscriptions and the assents of the bank creditors are in hand by October 27, 1908.

"The formal announcement of the plan and of its terms and conditions will be made the early part of next week."

THE FALK COMPANY'S PLANT.

THE FEATURES OF INTEREST OF A MODERN STEEL FOUNDRY AND MACHINE SHOP.

The Falk Company, of Milwaukee, Wis., operates the largest steel foundry and machine shop in the West. This plant has many features of special interest, particularly as concerns the economical arrangement and operation of the works.

The business of the Falk Company was started in an establishment devoted especially to the manufacture of street railway motor gears and track appliances. This department still constitutes an important division of the works, but the features of particular interest at this time are the foundry and power plant, the former a building 625 feet long and 295 feet wide at its largest part, having a capacity of 1,500 tons monthly. Steel castings of any size required up to forty tons capacity or more, and varying widely in character, are turned out.

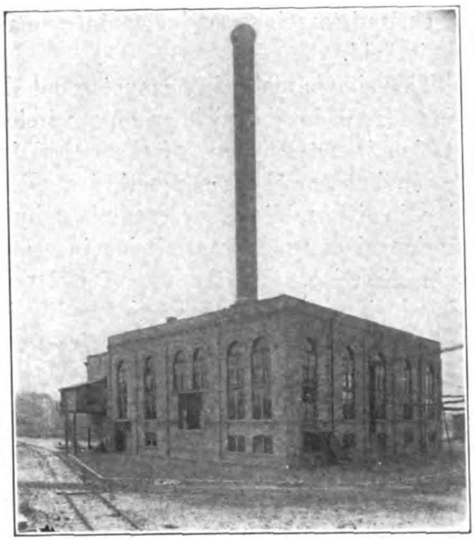
Pig iron is brought to the works over the Chicago, Milwaukee & St. Paul Railway, and left standing in cars on any one of the network of tracks which occupies a considerable portion of the company's ground. The cars are unloaded by means of a Cutler-Hammer two-ton lifting magnet at the end of a locomotive crane, and placed in piles between the tracks. An average analysis of each pile of pig iron or scrap is made, and the magnet is again called into play to load the iron directly into charging buckets carried on small industrial trucks. A record of the weight and contents of the buckets is then made, and the buckets are drawn up an incline to the charging floor of the furnaces. Charging machines feed the contents to one of two open-hearth furnaces, which are heated by oil fuel, which, after delivery in tank cars, is stored in three underground steel tanks, each with a capacity of 15,000 gallons.

The foundry is served throughout its length by eight traveling cranes built by Pawling & Harnischfeger, of Milwaukee.

The floor of the foundry is lighted in the daytime by side windows and a monitor extending the entire length of the building. At night arc-lamp illumination is used. The shops are heated in winter by means of the National Blower Company's system, which consists of forcing hot air through pipes running along the top of the building.

Unusually successful results have been obtained in this foundry by the use of electric welding. Bars welded by this method have stood tests of tensile strength up to 58,000 pounds per square inch.

The railway department of the Falk Company turns out cast-steel gears and forged-steel pinions, girder rail and high T-sections for city railways, low standard sections of from fifty-six to 100 pounds for steam and interurban lines, and a great variety of special work. This department has an exceedingly well-equipped machine shop.



Power Plant of the Falk Company, Milwaukee, Wis.

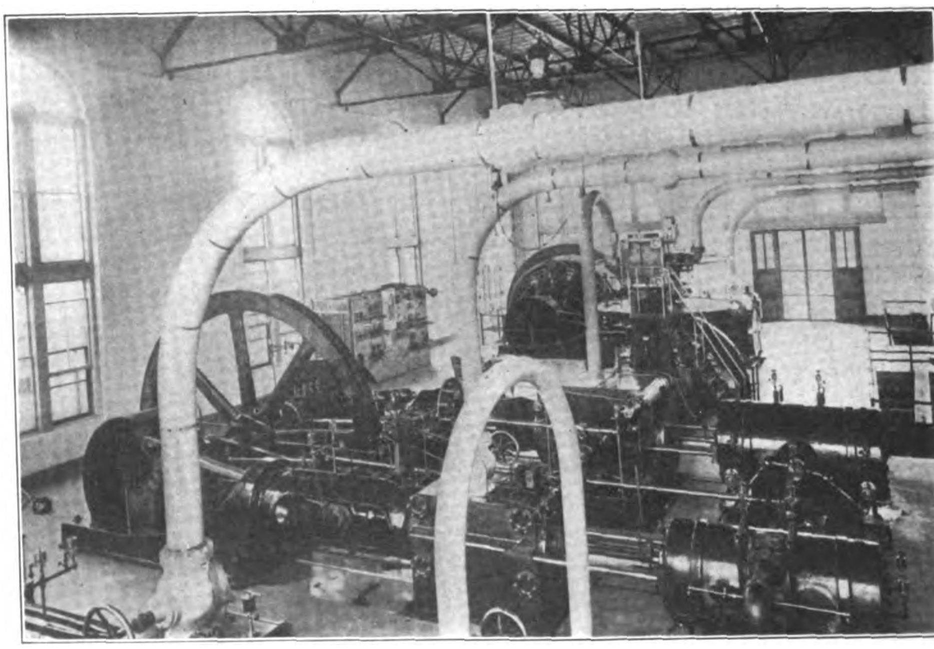
All of the work of the railway department is laid out and assembled before shipment. The laying out of the work is greatly facilitated by means of a special revolving crane of five tons' capacity.

All of the machinery in the entire works of the company which does not depend upon compressed air for its operation is electrically driven, principally by individual motors. In some instances short lines of shafting are used in such places as the pattern shop, cleaning department of the foundry, etc., where numbers of light-running machines make this arrangement most advantageous.

Electricity and compressed air are supplied from a new central power station, which is one of the most interesting features of the works. The equipment in all of its main details, including engines, generators, compressors, circulating pumps, etc., was furnished by the Allis-Chalmers Company, of Milwaukee, Wis.

The machinery consists of a cross-compound, condensing Reynolds-Corliss engine, twenty inches and forty-two inches by forty-two-inch stroke, operating at 100 revolutions per minute, and coupled to a 550-kilowatt, direct-current, 250-volt generator; an eighteen-inch and twenty-four-inch simple condensing Reynolds-Corliss engine of the vertical pattern, direct-connected to a 125-kilowatt, direct-current, 250-volt generator; and two air-compressors, one two-stage and the other single-stage, having capacities of 2,500 and 1,800 cubic feet of air per minute.

Lubrication is provided for the cylinders by sight-feed oil pumps and a gravity system. The oil flows after use to a five-chamber Turner filter, situated in the basement, and is pumped back to a 200-gallon tank located under the ceiling of the engine room.



Engine Room, Falk Company, Milwaukee, Wis.

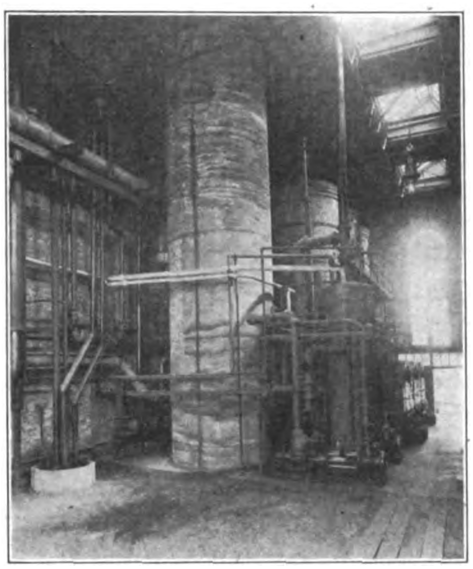
Three Wickes vertical water-tube boilers, designed for a working pressure of 150 pounds, and rated at 300 horse-power each, are located in the boiler room. These boilers are connected to a twelve-inch header, which divides into six-inch feeders serving the several engines. Steam is supplied at fifty pounds' pressure through large separators connected with Squire's traps.

All water for boiler feed is taken from the city mains, and first passed through the jackets and inter-coolers of the air-compressors before flowing to an open Crowley heater. Thence it is lifted to the boilers by one of two Burnham outside-packed plunger pumps of the Union Company's design, the second unit being used to work the turbine flue cleaner and for boiler washing.

Each furnace has independent dampers between it and the breeching, which connect with a reinforced concrete stack 180 feet high, having natural draft through an eight-foot flue. Each of the engines is connected to one of four Tomlinson barometric condensers built and installed by the Allis-Chalmers Company. The water flows from a nearby river to a deep well, where it is lifted to the condensers by means of steam-driven centrifugal pumps, one pump supplying two condensers.

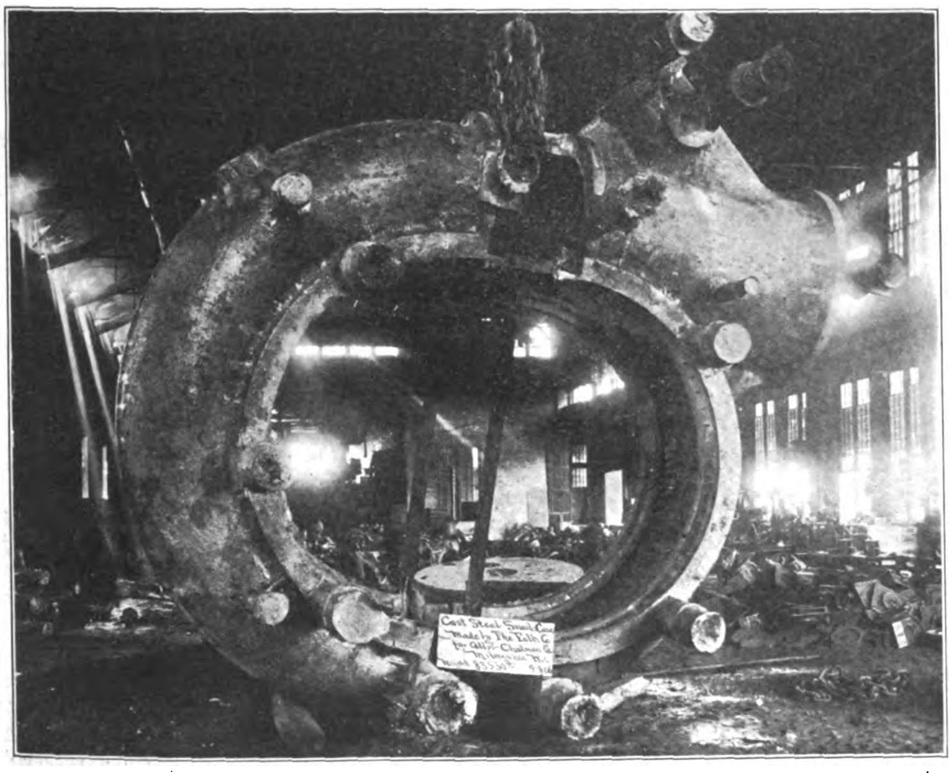
Coal is brought in on an inclined track and dumped over enclosed bunkers having a capacity of 400 tons, the cars being pulled by means of an electric hoist.

The switchboard was built by George F. Rohn, of Milwaukee, and is equipped with standard apparatus, including Cutler-Hammer switches. The distribution of current to the shops is through insulated underground cables, which feed a network of wires run in iron piping to the various departments where power is needed.



Boiler Room of the Falk Company, Milwaukee, Wis.

The plant is thoroughly equipped with modern appliances for conducting efficiency tests and gathering daily records, all of which are kept in constant service. This has had a very appreciable effect on the operating economy.



Cast Steel Snail Case, Made by the Falk Company for the Allis-Chalmers Company.

The company started in 1899 at its present site with a plant extending over less than a quarter of an acre. The present works have now an area of fifty acres, including a covered floor space of nearly ten acres. This rapid extension of the business is due to the efficient management of the works themselves, an interesting feature of which is the treatment of the employés and their relations to the officers and heads of departments. The company has demonstrated its ability to produce satisfactory castings, not only of a general character, but also those of the most difficult nature. In this way it has established itself with the largest and most particular users of steel castings in America.

The officers of the Falk Company are: Herman W. Falk, president; Otto H. Falk, vice-president; Charles L. Jones, second vice-president; E. A. Wurster, secretary and treasurer; Clarence R. Falk, works manager; Harold Falk, general superintendent; W. Frank Carr, chief engineer.

Annual Meeting of the Rejuvenated Sons of Jove.

The sixth annual meeting of the Order of the Rejuvenated Sons of Jove will be held at the Iroquois Hotel, Buffalo, N. Y., October 14, 15 and 16.

The meeting will open with a reception at 8 o'clock on Wednesday evening, October 14, at the Iroquois Hotel. At 10 P. M. there will be a special event for the entertainment of the Jovians.

At 9 A. M. on Thursday a trip will be made to the plant of the Roycrofters, at East Aurora, N. Y. At 10.30 A. M. an address will be made by Elbert Hubbard. At 12.15 o'clock luncheon will be served.

A business meeting will be held on Thursday at 2.30 P. M., at the Hotel Iroquois. Reports will be made by the auditing, financial and reorganization committees, and the officers of the sixth Jovian congress will report.

At 8 P. M. there will be an illuminated Jovian parade. At 9 P. M. there will be a grand rejuvenation at the cathedral of the Scottish Rite Masons. At 11 P. M. there will be a joviation, including a Dutch lunch, music, songs and speeches.

On Friday, October 15, a general meeting will be held at 10 A. M., when unfinished business will be taken up, and there will be a general discussion as to the needs of the order.

At 1 P. M. there will be a standing luncheon, and at 2.30 P. M. election and installation of officers.

The annual banquet will be held on Friday evening, at 7 o'clock.

Electrification of Steam Roads.

At the meeting of the Electric Club, of Chicago, Ill., on September 23, F. A. Sager, of the Arnold Company, delivered an address on "The Electrification of Steam Railroads."

"The railroads," he said, "will have to spend approximately $5,000,000,000 within a few years to keep up with the increase of traffic. By electrification at a cost of $4,000,000,000 they would increase their capacity to such an extent that no new trackage would be needed."

The meeting of the club was the first of a series which will be held for the purpose of throwing light on the electrification problem, and especially that of the Illinois Central suburban service.

In his address Mr. Sager took into consideration the work which had been done by the New York Central, the Baltimore & Ohio, the New York, New Haven & Hartford, the Erie and the New Jersey lines in the East, and at the St. Clair tunnel near Detroit.

The paper was followed by a general discussion in which the local situation was discussed, consideration being given to the difficulties which probably would be encountered, but the general opinion expressed was that the work offered no insurmountable obstacles.

"Electrification of the steam lines has been made slow chiefly for one reason," said Mr. Sager. "The men who have been trained by the old lines to high positions have a thorough knowledge of steam engineering, but little information as to electricity. On the other hand, the electrical engineers have been thoroughly trained in their specialty, but have not given their attention to the problems of the steam roads.

"The result is that the steam roads have had to call in electrical experts whose knowledge, as far as the old transportation went, was theoretical. They were unable to give past examples and experiences to add weight to their promises. But in practically every instance things have turned out, as to economy and efficiency, as the electricians said they would.

"It always has been thought that electricity could be applied with best results where the passenger traffic was large and broken up into frequent trains. Doubt was expressed as to the feasibility of applying electricity to the moving of freight. But the experiments have gone far enough to show that electricity far exceeds steam in economy and efficiency in three ways, as follows:

"At terminals where there are an unusual number of trains to handle. It is possible that legislators will come to realize this to such an extent that terminal electrification will be required by law.

"In mountain regions where there are heavy grades. Electricity will move trains more rapidly, with lessened cost of operation.

"At interior points where there is congestion due to large freight yards, junctions and unusual local traffic.

"It has been shown that electricity will very considerably reduce the cost of operation in suburban service. A very large economy has been shown in the eastern experiments, ranging from twelve to twenty-seven per cent. These savings were made when the initial expense of installation was still hanging on. As the extent of installation is increased the economy will be more marked.

"Necessity, however, will be the great factor in driving the roads to electrification. If money is still as hard for them to obtain when traffic starts to move again as it was a year ago, they will be driven to electrification in self-defense.

"It has been proved that the electric locomotive is forty per cent more efficient than the steam engine. It starts more quickly, moves more rapidly and will increase the capacity of switching yards on through tracks fully two-fifths. In other words, the installation of electricity would save millions and millions of dollars in new trackage and car equipment."

The Meeting of the Colorado Electric Light, Power and Railway Association.

The sixth annual meeting of the Colorado Electric Light, Power and Railway Association was held at Glenwood Springs, Col., September 16, 17 and 18. The first session was held at 4 o'clock, Wednesday, September 16, when a paper by S. E. Doane, chief engineer of the National Electric Lamp Association, was read. The next session was held at 8 o'clock Wednesday evening, when a paper entitled "The Operation of Hydroelectric and Steam Plants in Parallel" was read by J. C. Lawler, of Colorado Springs.

The third session was held at 10 o'clock Thursday morning, and papers were read by George Raymond Hall and John M. Mulvihill entitled, respectively, "The Electrification of Steam Railroads Operating in Mountainous Districts" and "The Popularizing of Public Utility Corporations by Careful, Painstaking Office Management."

The last session was held on Friday morning, when a paper by Clarence Renshaw, entitled "Some Notes on Single-Phase Railway Systems," was read.

The entertainment features of the meeting consisted of a trip on a special train on Friday afternoon to the works of the Central Colorado Power Company at Shoshone. The members made a thorough inspection of the dam, tunnels, building sites and tower construction.

On Thursday evening there was a rejuvenation of the Sons of Jove.

About thirty-five members and thirty-five associate members of the association were in attendance at the convention.

The following officers and committees were elected:

J. F. Dostal, Denver, Col., president.

W. T. Wallace, Cañon City, Col., vice-president.

J. C. Lawler, Colorado Springs, Col., secretary and treasurer.

Additional members of the executive committee—George B. Tripp, Colorado Springs, Col.; W. G. Matthews, Denver, Col.

Advisory committee—John A. Beeler, Denver, Col.; W. J. Barker, Denver, Col.; John F. Vail, Pueblo, Col.; C. K. Durbin, Denver, Col.; J. A. Cooper, Denver, Col.

Membership committee—L. M. Cargo, Denver, Col.; J. C. Davidson, Denver, Col.; C. H. Williams, Denver, Col.

Finance committee—Irving Hale, Denver, Col.; John A. Clay, Silverton, Col.; W. P. Eyre.

The Southern Idaho Irrigation Project.

J. G. White & Company, Incorporated, engineers and contractors, 43-49 Exchange Place, New York city, have commenced work on their contract to construct for the Idaho Irrigation Company, Limited, a complete irrigation system for about 150,000 acres of land situated in Southern Idaho. The water supply for this project will be obtained from Big Wood and Little Wood rivers. The lands to be irrigated are in the vicinity of Shoshone, Richfield and Gooding.

The irrigation system will consist of a storage dam, four diversion dams, four main channels, each leading to one of the tracts of land into which the project is divided and the complete system of distribution and drainage ditches necessary for the irrigation of these lands. The storage dam, which will form a reservoir of more than 150,000 acre-feet capacity, is to be built in the channel of Big Wood River in a lava cañon and is to be about 115 feet high, of rock-fill type with concrete core.

The diversion dams, two of which will be in the channel of Big Wood River and two in the channel of Little Wood River, are relatively small structures of sufficient height to raise the water to the level of the canals.

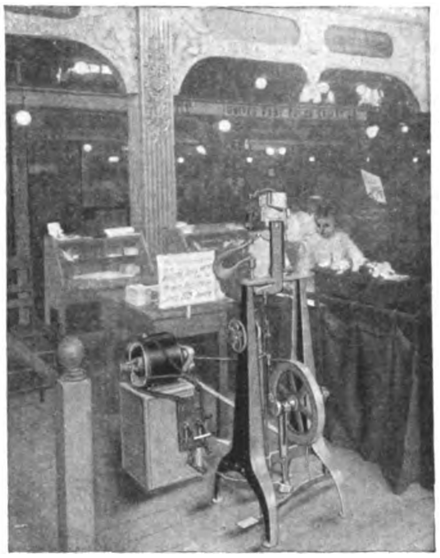
Electrical Machinery at a Shoe and Leather Exhibit.

The third annual National Shoe and Leather Market Fair, held at the Coliseum, Chicago, August 26 to September 2, was the most successful fair of its kind ever held. An idea of its size may be had from the fact that the huge Coliseum—the home of the Chicago Electrical Show—was completely filled with shoes, leather, machinery used in the shoe and leather industry and supplies. The decorations this year were even more elaborate than last year and, as they were uniform throughout, the effect was particularly pleasing. This applied not only to decoration but to the general arrangement of the booths as well. Each booth, being of a standard size and furnished throughout with mission furniture, gave each exhibitor an even chance to display his products.

Shoes were much in evidence of course, every kind from fine ladies' to men's high-top hunting boots being shown. This gave the retailer an opportunity to compare them side by side and get a line on the merits of each. To the average individual, however, this part of the display was not as interesting as the shoes in different stages of manufacture. Shoemaking and repairing machinery was shown in the Annex and it was here that the crowds lingered, watching some labor-saving machine do the work formerly done by hand. All these machines were driven by electric motors, both individual and group drive being used.

Booth of the Western Electric Company at the Shoe and Leather Fair.

Although the shoe and leather industry is a comparatively new field for electrical apparatus, great interest was shown by both exhibitors and visitors in the exhibit of the Western Electric Company. This company occupied a large booth in the Annex. Here both direct and alternating-current motors, arc lamps of various designs, exhaust and desk fans, and intercommunicating telephone sets were displayed. In addition to the motors shown in the Western Electric exhibit, Western Electric motors were seen in operation driving the shoemaking machines of other exhibitors. The arc lamps, too, on account of their brilliancy, brought a good many inquiries as to their adaptability to store and factory lighting and their superiority over the gas arc and



Bragg Automatic Shoe Nailer Driven by Western Electric Motor.

other forms of illuminants. This was particularly true of the Hawthorne "Short Arc" lamp, which, on account of its compact design—it being only twenty inches over all—met with general favor from those who, up to this time, had been unable to use arc lamps because their factories had low ceilings. The intercommunicating telephone sets for store and

Champion Shoe-Repairing Outfit Direct-Driven by Western Electric Motor.

factory use also came in for their share of attention from those interested in saving the time lost by the old walking-talking method of handling business. Many people were impressed with the advantages of an electric fan when they walked into the draft made by a sixteen-inch desk fan placed on a table near the aisle. The effect was particularly pleasing, however, for during the fair the Coliseum was uncomfortably warm and this booth was the one cool place in the building. Bulletins showing electrical apparatus designed especially for the shoe and leather market were distributed as well as general publications relating to lighting, power and telephone apparatus.

The Western Electric Company was very much in evidence throughout the fair and attracted quite a bit of favorable comment for its aggressive advertising. In the exhibits of four of the shoe-machinery companies whose machines were operated by Western Electric motors, namely, the Champion Shoe Machinery Company, the Puritan Manufacturing Company, J. E. Bragg & Company and the Dayton Last Works, were hung placards calling attention to the fact that the motors used were of Western Electric manufacture and that other electrical apparatus could be seen at the booth of the Western Electric Company in the Annex. This idea was further carried out by a placard hung in the Western Electric Company's booth explaining that Western Electric motors were in operation at the booths of these other companies.

A striking example of the efficacy of the moving exhibit was evidenced by the crowds which gathered around the booths where machinery in actual operation was exhibited. One of the best examples of this was the exhibit of the Champion Shoe Machinery Company. This exhibit showed a shoe-repairing outfit and harness-sewing machine. The repairing outfit consisted of a shoe stitcher, an edge trimmer, an edge cutter and a dust collector, all mounted on a common base and driven by a small, 110-volt Western Electric motor. The outfit was fitted with friction clutches which enabled the operator to put in operation any one part or the entire equipment at will, thus saving power and making this repairer a very economical machine. The dust collector is of much importance to the retailer because without it he would not be able to install his repairing outfit on the same floor with his shoe stock on account of the dust and dirt common to shoe repairing.

The entire equipment requires but one horse-power for its operation and runs at 500 revolutions per minute. The electric motor being a cheap, clean, reliable source of power, easily available at all times, is an ideal source of power here.

The Puritan Manufacturing Company also had an interesting exhibit of sewing machines. These were driven from a line shaft under the table on which the machines were mounted. A one-and-one-half-horse-power Western Electric direct-current motor was belted to this shaft and from the shaft a short belt ran up to each machine. This was an excellent example of group drive as applied to a number of similar machines.

The only moving sign at the fair was that in the booth of the Dayton Last Works. This sign, which was driven by a small direct-current Western Electric motor, was used to call attention to a line of shoe lasts known as the "Tread-strate."

J. E. Bragg & Company showed a new automatic nailing machine which, on account of the rapidity with which it operated, attracted a great many people to the booth of this company. This machine, known as the Crowe automatic shoe-nailing machine, is very simple in operation and at the same time very efficient. The nails are placed in a hopper and automatically fed down into a slot. The machine was driven by a small Western Electric direct-current motor similar to the one used by the Champion Shoe Machinery Company.

From every standpoint the fair was a success, as it brought together all the prominent shoe dealers and manufacturers and gave them an opportunity to study new methods of manufacture and see in actual operation the very latest labor-saving machines. The interest shown by the exhibitors and visitors at the fair in the electric motors and supplies showed that the shoe and leather field is one offering great opportunities to the manufacturer of electrical equipment.

To Discuss Railway Topics.

The executive committee of the National Association of Railway Commissioners has arranged for special addresses to be delivered at the meeting to be held at the rooms of the Interstate Commerce Commission in Washington, on October 6, as follows:

"Government Mediation in Railway Labor Disputes," by Martin A. Knapp, chairman Interstate Commerce Commission; "Regulation of Railway Capitalization," by Frank W. Stevens, chairman Public Service Commission, Second District, New York; "Car Efficiency," by Arthur Hale, chairman Committee on Car Efficiency of American Railway Association; "Uniform Rules Governing the Shipment and Carriage of Explosives and Other Articles Dangerous to Transport," by Dr. C. B. Dudley, president, and Colonel B. W. Dunn, chief inspector Bureau for the Safe Transportation of Explosives and Other Dangerous Articles.

Public Service Commissions.

At the recent meeting of the Vermont Electrical Association, in Bennington, Glenn Marston delivered an address on "Public Service Commissions," making some very interesting points, among which may be quoted the following:

"Every broad-minded person recognizes that in the main the interests of the public service corporations and the public are identical and that the object of a public service commission is to preserve this identity. A public service commission must protect the public and the corporations alike. The public is looking for the best possible service at the lowest possible rates; the corporation is looking for the most profitable business and realizes that it can only do its maximum amount of business by meeting to the fullest extent the wishes of the public. A public service commission should have the power to regulate rates, the quality of service, prevent competition, enforce satisfactory accounting and exercise a general supervision over the public utilities of the state.

"State regulation is far superior to any other method yet devised, because it removes the oversight of public utilities from local authorities. In the first place local regulation, and by that I mean either municipal ownership or municipal regulation of private companies, can not be provided by men familiar enough with the operation of the plants so regulated to make it trustworthy. The result is either an unfortunate laxity or a degree of municipal interference that sometimes goes so far as to put the company out of business.

"I want to emphasize the importance of a reasonable appeal to the courts from the decision of any commission which may be formed in this state. There should not be an unlimited appeal, because then a company might run to the courts at any time and tie up the decisions of the commission indefinitely. On the other hand, if no appeal is provided for, a corrupt or arbitrary commission would have powers which would put the companies absolutely at their mercy and the commission would not operate for the benefit of the public at large. It seems to me that the best way to provide for an appeal from the acts of the commission is to specify that the appeal shall be made within a certain time limit, say thirty days, and that it should be granted preference over all other cases in the court to which the appeal is taken.

"As to the duties of the commission, one of the most important is the enforcement of a uniform system of accounting, not only for the municipal plants but for the private companies. Municipal ownership has been consistently opposed by private companies for many years, not so much because the companies are opposed to municipal ownership in itself, but because they are opposed to the false and misleading accounts which are given out by the municipalities and which claim to show that the municipalities can manufacture electricity for less money than is possible under private ownership. A uniform system of accounting is just as valuable to the small company as to the large company—perhaps it is more so. I often hear the manager of a small company object to uniform accounting on the ground that his company can not make a good showing. That is the very reason why he should favor a commission which would enforce uniform accounting, because if it can be shown that his company does not operate profitably under the same accounting system as is used by the larger companies, he would be fully justified in going before the commission and asking that his rates be increased, so that he could operate at a reasonable profit.

"State regulation makes municipal ownership unnecessary. It makes it unnecessary for a city to invest a large sum, when the money could be used for other purposes more advantageously. It makes competition unnecessary for it takes the place of competition. All that can be looked for from competition is a desire on the part of each competing company to give better service and lower rates than the other, in fact, the rates can not be at their lowest when there are two competing companies because fixed charges must be met on unnecessary duplicate equipment.

"You may say, 'Why not competition in this business the same as in the grocery business?' The answer is that the grocer does not have to make a huge initial investment in complicated machinery and equipment with which to serve his customers, but buys his manufactured commodity from the wholesaler and acts as a distributing agent only, while the lighting company has to spend thousands of dollars before it can secure a single customer. It is the huge wastefulness of competition in public utilities that makes some other form of public regulation necessary, and it is only through the most generous co-operation of the public and the company that the lighting business can be made to attain its greatest usefulness and become the standard of enlightened business progress before the world."

A Modern Lamp-Making Works.

The New Factory of the Westinghouse Lamp Company at Watsessing, N. J.

WHAT do good light, pure air and pleasant surroundings mean to an employé? Whatever the answer may be, they mean just the same thing to the manufacturing business itself. These and the continuity of to work in rooms always filled with a plentiful supply of pure air. Although these new works of the company have been operating but a few months the reports of output in quantity and quality of the product stand as conclusive evi- strength to permit the addition of one or more stories when desirable.

All buildings are designed to be as nearly fireproof as possible, being constructed throughout of reinforced concrete.

GENERAL VIEW OF FACTORY AND GROUNDS OF THE WESTINGHOUSE LAMP COMPANY, AT WATSESSING, N. J.

operations in lamp manufacture are what the architects and engineers had in mind when they designed and constructed the works of the Westinghouse Lamp Company at Watsessing, N. J. A visitor to the works is struck by the unusually favorable condition under which the employés work. Tidiness is noticeable in every department. There is no crowding of employés; no foul air to make them drowsy and inefficient long before the day is done. High ceilings and plenty of windows make it possible for all dence that an employé will do more work and better work if placed amid surroundings that are healthful and inspiring.

The plant, which occupies a level site comprising fifteen acres of land, consists essentially of three structures—main manufacturing building, 521 by 100 feet, three stories high, with a floor-to-floor height of seventeen feet four inches; storehouse, 140 by eighty feet, four stories high, and power-house, eighty-three by sixty-six feet. The foundations of the buildings have been made of sufficient

Lighting and heating are supplied from a central power plant, which furnishes current for elevators, pumps, fans and for manufacturing operations.

The power-house is directly back of the storage house and is designed to contain 1,000 horse-power of Stirling boilers. The following installation furnishes the necessary power for the operation of the works at the present time:

One 250-kilowatt, alternating-current, direct-connected Westinghouse unit, with one twenty-five-kilowatt exciter; one fifty-kilowatt, alternating-current, direct-connected Westinghouse unit, with ten-kilowatt exciter; one ninety-kilowatt belt-driven generator; one forty-horse-power Westinghouse motor-generator set to supply direct current; one steam-driven air-compressor supplying air at from three to five pounds pressure for blow-pipe work; one motor-driven air-compressor, belt-connected, to supply air at 100 pounds pressure for distribution through the manufacturing building.

As a part of the power equipment, although placed in the manufacturing building, in the south end of the first floor, electrically driven, are seventeen vacuum pumps.

All mechanical processes are operated by electric drive, and the latest and best appliances used in lamp manufacture have been secured. Many of the machines used in these new works have been developed by the company's engineers and the company has built the machines at the works.

The buildings are heated by indirect radiation, large stands of heating stacks being provided on the ground floor, through which the outside air is drawn by electrically driven fans and distributed in galvanized-iron ducts through all parts of the buildings. Hot water is circulated through the heating stacks by an electrically driven centrifugal pump located in the boiler room of the power-house, where the water is heated by exhaust steam.

Special attention has been given to the matter of fire protection, and the entire plant is equipped with automatic sprinklers, which are supplied with water from a steel tank of 100,000 gallons capacity placed on a tower 100 feet high. Further fire protection is provided by a system of underground piping in the yard connecting with fire hydrants. This system is fed by a 1,500-gallon Underwriters' fire pump, which draws its water from an underground reservoir of 200,000 gallons capacity. A reserve water supply is secured by connection with the regular water service system of the town of Bloomfield, N. J.

Fire-escapes are located on three sides of the main building, and one on the storage house. All stairways in the building are constructed entirely of cement and iron, so that these may be relied upon as safe exits in case of fire. On every floor the stairways are separated from the working sections by fire doors.

A volunteer fire department is organized among the employés, and there are stations on every floor with a full equipment of fire-fighting apparatus, including hand chemical extinguishers, fire buckets, axes, hose, etc. These stations are clearly indicated by red lights. The fire department has a further equipment of a chemical wagon, with a capacity of ten gallons.

In the manufacturing building all rooms are made especially, light, large and airy, and are finished in light gray. Toilet accommodations, carefully designed and equipped with a view to health and comfort, are provided at convenient points on all floors.

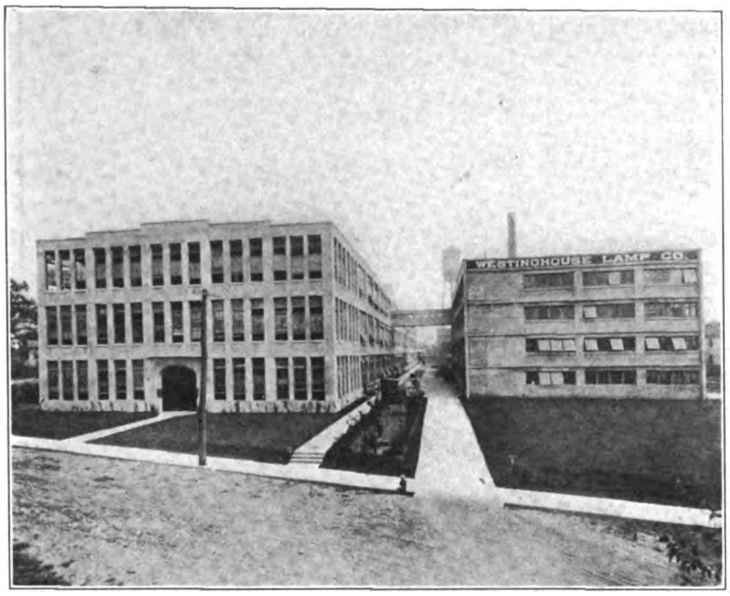
Drinking water is furnished on all floors at convenient intervals, from a well drilled to a depth of 550 feet on the company's property. This well supplies all the water needed for manufacturing purposes and fire protection.

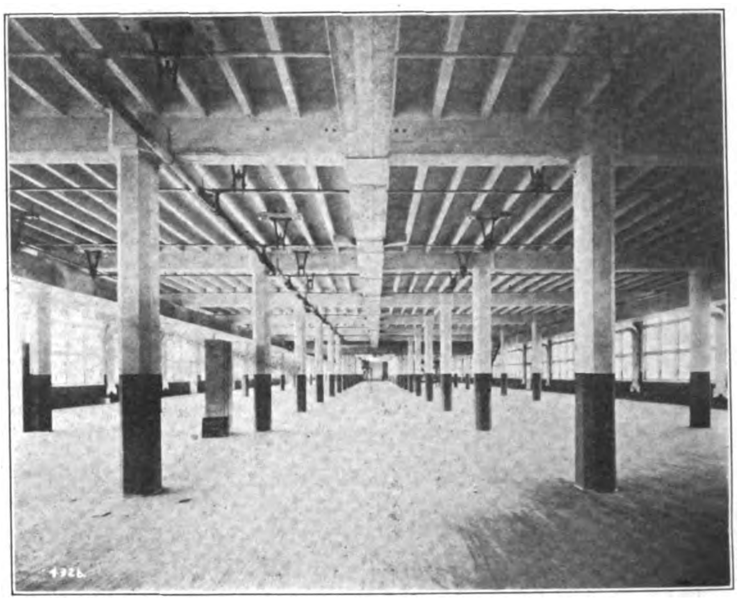
The storage house is the first building to be seen, coming from the railroad station. It was purposely placed adjoining the tracks of the Delaware, Lackawanna & Western Railroad and the Erie Railroad to facilitate the loading and unloading of material.

In the storage house are received and stored all the raw materials required in lamp manufacture. Starting at the storage house and ending in the same building is the best system of shop routine known to the art of lamp making. There is no back action to impede the work and every step is in one forward direction. There is interwoven with the manufacturing process so closely as to be part and parcel of it, a system of inspection and accounting, by means of which every important operation is inspected and approved by an expert before it is permitted to pass on to the next operation. A space on each floor of the main building nearest the storage house, about thirty feet wide and running almost its entire length, is reserved for the stores and inspection department.

It will be seen at a glance that this means to the customer a very high grade of product, and at the same time effects a tremendous saving to the manufacturer in preventing further operation on pieces once found defective.

It also makes it possible to operate the factory on the premium piecework system. Careful record being kept of the grade of work turned out by each operative, the inspector once a month is able to prepare for the management a statement showing clearly the quantity and grade of work turned out by each employé, as well as





View of Main Building and Storage Building, and Interior View of Factory Floor Before Occupancy, Westinghouse Lamp Company Factory, Watsessing, N. J.

the standing of one employé with another in the same class of operation.

The process of making the filament begins on the first floor of the main building. Here the filament undergoes fourteen operations, beginning with the preparation for the brew, the squirting into fibre, its washing, and later the winding of the fibre on drums which are electrically driven, each drum having one attendant to feed the fibre. Other operations include the forming of the filament on frames, then the packing, first for the preliminary furnaces and later for the final furnaces, then the sizing, cutting and counting. The counting, which is done by weight, is most interesting to the visitor, who is naturally surprised to learn that this method of counting is correct within two per cent, and is far more accurate than counting by hand.

The treating of the filament takes place on the second floor at the south end of the main building. Here there are four long treating tables, each providing room for eight operatives. Each operative has facilities for treating simultaneously four filaments in separate chambers of hydrocarbon gas. After this, inspection is made as to the length and cross-section of the filament, and check inspection is also made for resistance, shape, etc.

Reference should next be made to the process necessary to make the stem through which the leading-in wires are inserted before being sealed in the glass bulb. Glass in long tubes is cut into short lengths and fed into what are known as flanging machines. In point of economy of operation these are most interesting, being entirely automatic and requiring but one attendant to keep them filled and in adjustment. The hoppers at the top of the machines are kept filled with these short lengths, which, as they pass through the apparatus are heated on one end by gas flame and mechanically flanged.

After the insertion of the platinum-tipped leading-in wires, the anchor wire and the forming of the seal by an automatic clamping attachment which is a part of the stem-making machine, the finished stems pass through an inspection and stores department to long tables for the mounting of the filament. Here the stems are arranged in frames and the filament attached preparatory to the straightening of the leading-in and anchor wires. From this point the mounted stems, containing the leading-in wires, anchor wires and filament are passed through an inspection department to the sealing-in machines. However, we should now give some attention to the glass bulbs which, after having been washed and placed in the stores and inspection department, are taken to the tubulating machines, where by means of a needle gas-flame a tube is welded to the end of the bulb, which later provides a connection through which the lamp is exhausted. A large number of special tubulating machines are arranged

Lamp Basing Department, New Factory of Westinghouse Lamp Company, Watsessing, N. J.

on tables and there is one operator to each machine.

At the sealing-in machines the bulbs which have been tubulated meet the finished stems whereon the filaments have been mounted. These machines are equipped with holders for both the bulbs and stems, which are brought together in the proper position by the operator, and by mechanically rotating in an eight-flame gas blast the steam is sealed in the bulb, the joint being air-tight.

The special machines which are used for creating the vacuum in the bulb are provided with two-cylinder exhaust or vacuum pumps. Each operator has two lamps on the machine at once so that no time is lost during the process, as while one lamp is being subjected to the action of the exhaust pumps the other is being sealed off, that is, the tube which has been attached to the bulb in the tubulating process and through which the exhaust pump is drawing on the bulb, is fired off by hand into a symmetrical tip.

The bulbs which have been sealed in and exhausted pass through the stores and inspection department for examination and counting and then go down to the second floor for photometering. Here a force of experts test the lamps in darkened rooms to determine the rating, which is marked on the bulb in each case. From here the lamps pass to the first floor, where they meet the bases and where by means of rotating machines in which the bulbs are placed the bases are affixed and soldered by gas fire.

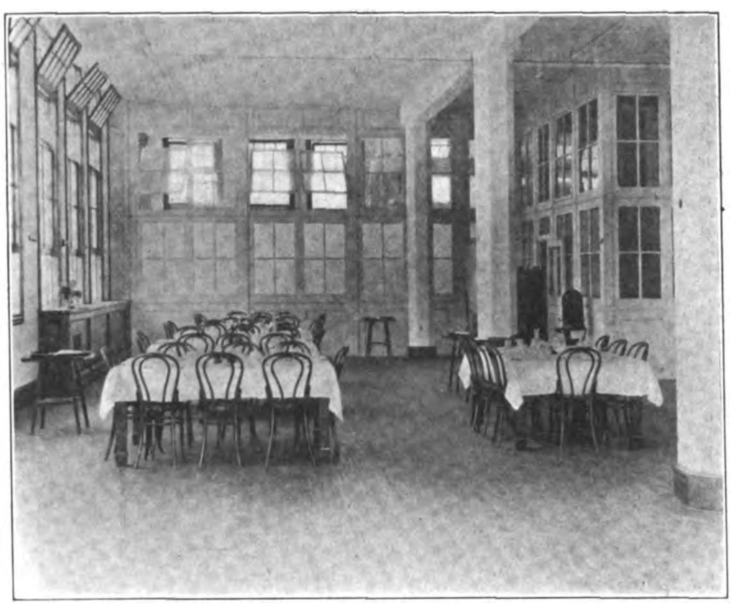
Such of the lamps as are packed for immediate shipment pass over to the shipping room. Stock lamps are carried to the upper floors of the storage house and held subject to order.

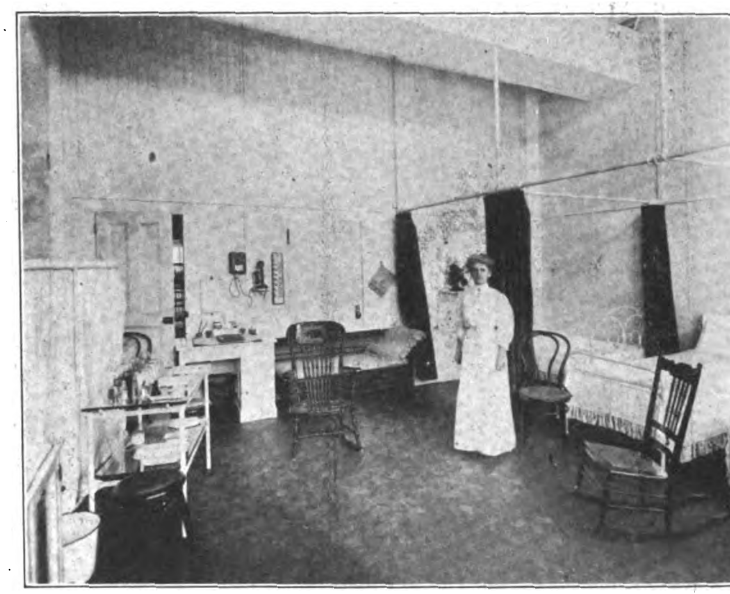
A special branch of manufacture not yet mentioned is the tungsten lamp manufacturing department, which occupies most of the second floor in the main building of the works and is devoted entirely to the manufacture of tungsten lamps, the larger quantities of which are made in the forty, sixty and 100-watt sizes. In the manufacture of tungsten lamps it has been the aim of the company to produce a highly efficient lamp which should be known everywhere for quality. The operations through which the tungsten lamps pass are too numerous and varied to explain in this article. However, it may be mentioned in passing, that for the operation of this department a large generating station has been provided for the making of hydrogen and nitrogen gases, and close beside this station is a large holder in which these gases are stored.

In the front of the building (the north end), on the first floor, are the private offices of the general manager and the assistant general manager; also of the correspondence and general offices, as well as the telephone exchange connecting with all departments.

Immediately above these offices on the second floor, and reached by means of a double stairway built of concrete, are the offices of the treasurer and auditor, the engineering department and the manager of works.

On the third floor, and also in the front of the buildings, are the dining rooms. There is a large dining room for the office employés, the foremen and their assistants, and private dining room for the officials of the company. Both dining rooms are directly connected with the kitchen.





Employé's Dining Room, and Medical Room, Westinghouse Lamp Company Factory, Watsessing, N. J.

Within the organization has been voluntarily formed by the foremen and their assistants, an organization known as the Westinghouse Foremen's and Assistants' Association. This organization has the hearty endorsement of the management of the company and is encouraged in every way in its endeavor to foster and develop a spirit of co-operation, one with the other, in the work of the various departments.

Meetings for the discussion of subjects pertaining to the interests of the company and employés are held at regular intervals, and outings are frequently held during the summer months.

In the near future it is the intention to equip, close by the works, a club, the building for which is now available. A library, reading room, shower baths, bowling alleys, billiard and pool, and other requisites of a modern social industrial club, will be provided.

Close by the works, on the company's property, is a baseball ground, upon which many of the employés play at noon and spare hours.

A unique feature in the organization of the Westinghouse Lamp Company is a dispensary and a rest-room for the employés. A regular physician has entire charge and gives undivided attention to this work, being on hand at all times to render medical advice or assistance when needed. Every needful thing is provided for the care of an employé who may be injured while in the performance of work, and other less important ailments are attended to and the medicine furnished without charge to the employés.

The entire work of designing and constructing was done by Westinghouse, Church, Kerr & Company.

THE DISCOVERY AND DEVELOPMENT OF THE LAWS OF THERMODYNAMICS.[1]—II.

BY DUGALD CLERK.

(Continued.)

Rankine, as early as 1849, arrived at the general equation of thermodynamics which expresses the relation between heat and mechanical energy and indicated the result of his investigations to the Royal Society of Edinburgh in February, 1850. Rankine thus arrived independently at the same result as Clausius about the same time. Both Rankine and Clausius, however, adopted certain theories as to the molecular structures and motions of gases, and their demonstrations to some extent depended upon their theories. To Thomson and Joule we are deeply indebted for the rigid proof of the two laws and for the rigid deduction of the modern scale of temperature and the determination of absolute zero in its modern form. Thomson now thus defines temperature:

"The temperatures of two bodies are proportional to the quantities of heat respectively taken in and given out in localities at one temperature and at the other, respectively, by a material system subjected to a complete cycle of perfectly reversible thermodynamic operations, and not allowed to part with or take in heat at any other temperature; or, the absolute values of two temperatures are to one another in the proportion of the heat taken in to the heat rejected in a perfect thermodynamic engine working with a source and refrigerator at the higher and lower of the temperatures respectively."

This definition leads to an absolute scale of temperature which is independent of the substance operated on, and Joule and Thomson's experiments have shown that this scale differs but slightly from that of the ordinary air-thermometer. Joule had suggested to Thomson, in a letter to him in 1848, that the probable value of Carnot's function is the reciprocal of the absolute temperature, as measured on a perfect gas-thermometer.

Thus Clausius appears to have anticipated Thomson, not in the suggestion of an absolute scale of temperature, but in the idea of an absolute zero founded upon the combination of Carnot's law and Joule's law. Thomson, in his papers, very modestly attributes the second law—the law of the transformation of heat—to Carnot and Clausius; but in this he undervalued his work, because Clausius appears to have assumed what Thomson and Joule proved—that is, the coincidence of the absolute scale with the air-thermometer scale.

It will thus be seen that the position usually assumed by the engineer at 1850, of the quality between heat given to the engine and heat given to the condenser, was fundamentally untrue. Without this deduction, however, no determination of values of the Carnot function could have led to the determination of an absolute zero. According to the material theory, as seen in the light of Carnot's cycle, a heat unit could give an indefinitely increased amount of work with lowering of the temperature. Nothing in the theory sets a limit to this increase and, accordingly, there is nothing to suggest an absolute zero. Immediately, however, we accept the dynamical theory of heat we find that one pound of water requires the exertion of 1,390 foot-pounds of work to heat it through one degree centigrade. We also know from the Carnot cycle that, under ordinary conditions of human existence, only a portion of this work can be returned; but as no conditions could conceivably exist in which a greater amount of work could be obtained from one pound of water than the 1,390 foot-pounds put into it to heat it through one degree centigrade, it follows that, inasmuch as the Carnot function increases with diminishing temperature, the limit of temperature is reached when, according to the Carnot cycle, the whole of that work, put into one pound of water, can be got out again as work. This limit is the absolute zero of temperature. No lower temperature is conceivable without introducing the idea of the creation of energy. So far as human beings are concerned, this idea is as inconceivable as the idea of the creation of matter. The determination of this limit with the close accuracy necessary for a well-founded constant is to be entirely attributed to Thomson and Joule. In his 1851 paper Thomson thus succeeds in answering the question which he put to himself in his 1849 paper and he supplies a quantitative method of connecting the amount of the thermal agency necessary with the amount of work which can be performed under varying conditions.

Engineers dealing with motive powers are thus deeply in debt to Thomson and Joule for the secure position occupied by them to-day.

The brilliant work of Meyer, published so early as 1842, is held by some to have anticipated to a large extent both the work of Thomson and of Joule. Undoubtedly Meyer formulated true ideas and carried his generalizations through a wide range. Helmholtz also very early arrived at similar conclusions to those of Joule and Thomson; but it has been thought better to discuss the work of Thomson and Joule separately in order to illustrate the transition period through which many distinguished minds were passing about that time. Undoubtedly, great credit is due to Meyer, Helmholtz, Clausius and Hirn, and Thomson himself recognized this in the most generous way.

The ideas of Thomson and Joule now form so much of the basis of all reasoning upon motive-power engines that there is some little danger to the present generation of forgetting what they owe to these two great men. To appreciate the step made by them it is necessary to consider the position of motive power produced by heat at about the middle of the last century. At that time many attempts had been made to displace the steam engine as a heat engine by air engines in various forms—both engines heated externally and those heated internally, now known as internal-combustion engines. Papers read at the Institution of Civil Engineers in 1845 and 1853, and the discussion of those papers by eminent men of the day, supply an accurate measure of the knowledge possessed by the engineer of the principles of action of his heat engines. Many distinguished names occur in these papers and discussions, including James Stirling, Robert Stephenson, Sir George Cayley, Charles Manby, James Leslie, C. W. Siemens, Hawksley, Pole, W. G. Armstrong (afterward Lord Armstrong), Edward Woods, E. A. Cowper, D. K. Clark, Benjamin Cheverton, Goldsworthy Gurney, George P. Bidder, Professor Faraday, Isambard K. Brunel, Captain Fitzroy and F. Braithwaite. At the date of the later of these discussions Brunel had already designed the Great Eastern, in 1852, with her engines of 11,000 horse-power. Armstrong was a Fellow of the Royal Society, and had started the Elswick Works and invented the Armstrong gun. Robert Stephenson was at the height of his fame. He was then a member of parliament, president of the Institution of Civil Engineers and a Fellow of the Royal Society. Siemens was a young man, but was busy on the regenerative furnace; he had considered regeneration as applied to steam engines, although his work on the air engine was still to come. All were distinguished men in their day, and their opinions may be taken as representing the very best scientific knowl-

[1] Presidential address delivered to the Engineering Section of the British Association for the Advancement of Science, Dublin, September 3.

edge of the leading engineers of the day. The first of the papers to which I refer is called "Description of Stirling's Improved Air Engine," by James Stirling, member of the Institution of Civil Engineers. It was read on June 10, 1845, with Sir John Rennie, the president of the institution, in the chair. The engine described was the later form of the well-known Stirling air engine, invented by the Rev. Dr. Stirling, a Scottish clergyman, in the year 1815. The development considered was the invention of the reader of the paper, a brother of Dr. Stirling. The main improvement consisted in the use of air at a greater density than the atmosphere, and the engine at that date had so far succeeded that two had been used at the Dundee Foundry Company's works, one giving about twenty-one horse-power and the other about forty-five horse-power. Practically, therefore, some success had been attained. Mr. Stirling claimed that the twenty-one-horse-power engine consumed fifty pounds of coal per hour, which is about two and one-half pounds per horse-power per hour. This was an extraordinarily good result for the time. At present, however, we are not interested in the practical result, but only in the opinions of the engineers of the day as to the fundamental principles of heat engines.

It is clear from the paper that the theory of the regenerator was entirely misunderstood. It was imagined that with a perfect regenerator no heat would be required to perform work. This is evident from Mr. Stirling's answer to Sir George Cayley. Sir George Cayley described his engine, which was of the internal-combustion type, acting with solid fuel under constant pressure, and showed that, owing to dust and heat in the cylinder and valves, his experiments proved abortive. He stated, however, that his engine had consumed six and one-quarter pounds of coke—equal to nine pounds of coal—per horse-power. To this Mr. Stirling answered: "It must be remarked that Sir George Cayley in following an entirely different object had overlooked the great leading principle of repeatedly using the same heat," and "he was of opinion that, except on that principle, the air could not be economically used as a moving power." Another speaker, Mr. Cottam, said: "It was evident that, if it was practicable to arrive at the theoretical condition of the absorption of all the caloric by the thin laminæ during the upward passage of the air, and the giving it out again during the downward passage, there would not be any loss of heat." Robert Stephenson did not appear to understand Stirling's air engine at all, because he made the following remarks: "He understood the process to consist of heating the air in a vessel, whence it ascended to the cylinder between numerous thin laminæ, by which the caloric was absorbed, to be again given out to the descending air. Now it appeared to him that, though the ascending process was natural and easy, the reverse action would require a certain expenditure of power, in the depression of the plunger." This remark clearly showed that Stephenson, notwithstanding his eminence as an engineer, at that date had not appreciated the essential conditions of the hot-air engine.

In the year 1853 the subject of the air engine again came up before the Institution of Civil Engineers, interest being excited evidently by the building of the large engines of the hot-air ship Ericsson in America, the engines having air cylinders of no less than fourteen feet in diameter. Four papers were read in this year: "On the Use of Heated Air as a Motive Power," by Benjamin Cheverton; "On the Caloric Engine," by Charles Manby; "On the Principle of the Caloric Air-Heated Engine," by James Leslie, member of the Institution of Civil Engineers, and "On the Conversion of Heat Into Mechanical Effect," by Charles William Siemens, associate member of the Institution of Civil Engineers.

Cheverton evidently considers, from his paper referring to Stirling and Ericsson, that "both parties also rest the efficiency of their engines on the repeated use of caloric. They contend that in recovering from the ejected hot air the caloric which gave it superior tension, and employing it in heating the injected air, 'it is made to operate over and over again.' Mr. Ericsson aspires to embody a new principle in motive mechanics—no less, to use his own words, than 'that the production of mechanical force by heat is unaccompanied by the loss of heat,' except such as arises from radiation, or other practically unavoidable waste." Cheverton rejects this idea, but, strangely enough, does not appear aware of the work either of Carnot or of Joule. He comes to the conclusion, however, that "caloric, doubtless, is in all its aspects a manifestation of force, and unquestionably, as a mechanical agent, of a dynamic force, and therefore is directly amenable to the third law of motion." He appears to think that heat is accompanied with molecular activity, but is puzzled by what he accepts to be a fact, that in the steam engine the whole of the heat of the steam as it comes from the boiler is found in the condenser. With regard to the steam he says: "Undoubtedly, in respect to the materiality of caloric, if it be material, it is transferred intact to the condenser, yet in its passage it may have parted with force, which it can not communicate again." He comes to the conclusion that the change may take place not in the quantity, but in the intensity of heat. Here he resembles Carnot; but it appears to him impossible to arrive at any useful theory of the heat engine, because he states: " . . . for every investigation leads to the conclusion that the effect of caloric is independent at least of the chemical, if not also of the physical, constitution of bodies. But economy of fuel is a different question from the economy of caloric; it is altogether a practical matter, and can only be determined by experiment; for this, and, indeed, most other points of practice, are too intractable to come within the grasp of the most powerful calculus." In the discussion a communication was read from Sir George Cayley, in the course of which he states, with regard to the regenerator: "There can exist no doubt of the effective reapplication of heat to an almost unlimited extent by this beautiful invention, due originally to Mr. Stirling, and now carried out to a greater extent by Captain Ericsson." Sir George Cayley discussed the difficulties of Ericsson's engine, but he accepts the principle that heat may give work and yet be used over and over again practically undiminished. Armstrong did not express himself upon the theory at all but he was doubtful as to the advantage of the air engine compared with the steam engine, although he believed that it was practicable to recover and use over again a large proportion of the heat applied, and he thought the balance of economy, so far as heat was concerned, would be found in favor of air. Siemens agreed to some extent in the advantages of a regenerator, but he showed clearly that expansion doing work was accompanied by a diminution of temperature, and stated that this heat had to be replaced by the fire. Bidder was of opinion that "no theoretical advantage was obtained in using heated air instead of vaporized water as a motive power, and it was incapable of being applied practically with as much convenience." It is most interesting to note that Dr. Faraday joined in this discussion. He said very little, and I will give his remarks complete. Dr. Faraday said: "Twenty years ago he had directed his attention to this question, and from theoretical views he had been induced to hope for the successful employment of heated air as a motive power; but even then he saw enough to discourage his sanguine expectation, and he had, with some diffidence, ventured to express his conviction of the almost unconquerable practical difficulties surrounding the case, and of the fallacy of the presumed advantages of the regenerator. He still retained his doubts as to the success of the innovation, and feared the eventual results, even of Captain Ericsson's spirited and ingenious efforts." Brunel considered the use of the regenerator to be an entire fallacy, and did not believe that the power derived from the expansion of air by heat could be used effectively and then be recovered and used again. Mr. Hawksley considered that the machine involved a mechanical fallacy and that the regenerator produced no mechanical effect whatever. Mr. Rendel was the president at the meeting which dealt with Mr. Cheverton's paper, and, in view of the great difference of opinion on the subject, he stated that "he would not have the meeting arrive at a hasty or erroneous conclusion on the question of this engine, and he therefore suggested that Mr. Siemens should draw up a paper on the subject, and that the members should collect, for a future meeting, all the information within their reach, in order to bring about the calm and deliberate discussion of the question." This resulted in the further meeting of May 17, 1853, when papers were read by Manby, Leslie and Siemens. The paper by Manby consists of the summary of a discussion by M. Galy-Cazalet, which took place in Paris in 1853. M. Galy-Cazalet comes to the conclusion that the regenerator involves a fallacy, and he concludes: "There appears to be at present so much doubt of the utility of the regenerator that it would be wise to abandon its use for a time, and by trials with a more simple form of caloric engine establish the fact either of the superiority or of the inferiority of heated air in comparison with steam as a motive power." Mr. Leslie, on the contrary, in his paper upholds vigorously the accuracy of the principle of the regenerator or economizer. He comes to the conclusion that it is based on true principles and is attended in practice with real economy of heat, and consequently of fuel. In this conclusion he is doubtless correct; the regenerator is useful and does economize heat. But Leslie goes much further than this; he appears to support Stirling in the fallacy that the regenerator may be made indefinitely useful. Stirling states:

"And thus it appears that by applying air successively to a series of bodies regularly increasing in temperature, and moving alternately from one end of the series to the other, it may be heated and cooled ten times, with an expenditure of caloric which would barely have heated it once, if it had been applied at once, to the hottest body—*i. e.*, beyond the series. It is evident, also, that if the series had been composed of twenty points, or bodies, having a difference of temperature of five degrees, the air might be heated and cooled twenty times at no greater expense of caloric. Nay, it is evident that by multiplying the members of the series indefinitely air could be heated and expanded and made to do work at no appreciable expense. But let no mathematician be alarmed with the idea of a perpetual motion, or the creation of power. There are many enemies to contend with in the air engine besides friction, which alone prevents perpetuity in some mechanical motions. We have no means, without consuming a part of our power, of applying the air so closely to the apparatus as to make it absolutely assume the temperature of the bodies to which it is applied. There is, therefore, a loss in the very act of heating and cooling."

Leslie comes to the conclusion that Stirling is right, but that an air engine without a regenerator would be a much less effective and economical application of heat than the steam engine. Leslie gives some interesting particulars of the later air engines of James Stirling. He states that an engine of forty-five horse-power was started in March, 1843, at the Dundee Foundry; that in December, 1845—two years and nine months after starting—one air vessel gave way, and in May, 1846, another failed, and in January, 1847, a third failed. This information was supplied to him by David Mudie, one of the lessees of the foundry.

(To be concluded.)

Explosion of the Gas-Bag Balloon at the Franco-British Exposition.

At the investigation, in the Hammersmith's coroner's court, to discover the reason for the explosion of the Lovelace gas balloon which occurred at the Franco-British Exposition some weeks ago, interesting information, says the *Electrical Engineer*, London, September 11, concerning the liability of sparks from electrical connections was brought out. The airship was kept in a tent open at both ends and with two openings on each side for ventilation. The interior of the tent was illuminated by electric lamps. A continuous wire ran along the poles and incandescent lamps were suspended from this wire. The wires were conducted through the ground to prevent short-circuiting, and the additional precaution of using cutout plugs had been taken. The envelope of the balloon was seventy-five feet in length and sixteen feet in diameter, cylindrical, and had a net over it for the purpose of suspending the machinery. An electric fan was used to circulate the air in the bag when the gas had expanded through the heat of the sun and to expel the foul air from the tent. The condition of the bag was tested by blowing air in by means of the fan for the detection of the presence of holes. In his evidence before the coroner, the owner of the air-ship, Captain Lovelace, stated that after the explosion he had examined the electric fuses and also the cutout plugs, and they were all right. The fan was driven by means of a wire run to a lamp socket. There was a switch on the fan, and unless the fan were turned over there would be no sparking. The assistant balloonist, in his evidence, said that when the bag was about two-thirds full of hydrogen gas, and for the purpose of distending it, another assistant sat on the ground and held the neck of the bag over the electric fan. The flames from the burning balloon, rushing down the neck, set fire to his clothing. Another witness stated that he saw the balloon being filled by the electric fan. Expert witnesses testified that the electrical arrangements were excellent, and that sufficient precautions had been taken so that if the tent were blown down the current would have been shut off. The fan was of good make, and was of a kind that frequently sparked. There was sometimes a spark in the brushes, but there was always a small spark at the switching off. If there was dust in the fan there would be some likelihood of sparks. The spark, though very minute, if formed in an atmosphere of hydrogen and oxygen, would be sufficient to cause an explosion. The jury, after some deliberation, returned a verdict to the effect that the deaths were caused by burns through the accidental explosion of the gas bag due to the use of an electric fan for pumping air into it. It added a rider to the effect that it considered the use of the fan to have been dangerous under the circumstances.

Breakdown of Electrical Machinery.

The report of M. Longridge, chief engineer of the British Engine, Boiler and Electrical Insurance Company, always forms interesting reading, and from the abstract of this report, published in the *Electrician*, London, we have been pleased to extract the following paragraphs:

The rate of breakdown was 1 in 11.7 among steam engines and 1 in 11.1 among gas and oil engines, as compared with 1 in 8.1 and 1 in 12.4, respectively, last year. It is interesting to observe that in both types of engine the valves and valve gear are believed to have failed more frequently than any other part, and that whereas the percentages of failures due to this cause in the twenty-four years previous to 1906 were twenty-one per cent for steam engines and 32.5 per cent for gas and oil engines, these figures stand at twenty-eight and 43.3 per cent, respectively, for the year 1907. Also in the case of gas and oil engines the next highest percentage of failures—*viz.*, only 13.5 per cent—was attributed to cylinders and cylinder ends, thus showing apparently that the weak point of this type of engine is its valves.

The chief engineer's remarks on this subject are as follows:

"The increase in the number of breakdowns of steam engines traceable to failures of valve gears is probably the result of increase in speeds and number of parts. The reduction in the number of breakages from spur gearing is the natural consequence of the substitution of rope and direct driving for the older system of transmission. The steady increase in the number of broken cylinders and pistons is due principally to the use of steam at temperatures and pressures higher than the parts can safely bear. The reduction in the number of main shafts broken is remarkable and inexplicable.

"In gas and oil engines the increase in breakages of valves and valve gears is not satisfactory, and demands the serious attention of makers of these engines. If all side shafts were fitted with ring lubricators and levers made of wrought iron or good cast steel the percentage in the table would be reduced. The reduction in broken cylinders and pistons is encouraging and marks the progress which is being made. Connecting rods proved less destructive than usual, probably because of improvement in design, particularly as regards strength of bolts. Breakages of crank shafts were fewer than in 1906."

An increase is again reported in the electrical branch of the business, and the number of breakdowns of dynamos and motors in 1907 exceeded the number in 1906 by 18.1 per cent, so that insurance is proving a benefit to the users of electrical machinery. The rate of breakdown was rather lower among dynamos and rather higher among motors than in 1906. The exact figures are 1 in 18.7 among dynamos and 1 in 7.9 among motors. The corresponding figures for 1906 were 1 in 16 and 1 in 8.2. Again, as in 1906, the rate among continuous-current machines was much higher than among alternating, but, on the other hand, the average cost of each breakdown was much less, so that the company's practice of charging practically the same rates of premium for both types of machine is fully justified. The proportions in which the various parts of the machines are thought to have caused or initiated the breakdowns of 1907 are tabulated below:

Part Which is Believed to Have Failed First.	Dynamos. 1906. Per Cent.	Dynamos. 1907. Per Cent.	Motors. 1906. Per Cent.	Motors. 1907. Per Cent.
Armatures and rotors	50	35	44	38
Magnet coils and stators	11	7	14	14
Commutators and brush gear	20	34	28	30
Miscellaneous	19	24	14	18
	100	100	100	100

Starting Switches and Controllers.	1906. Per Cent.	1907. Per Cent.
Resistance coils	48	60
Contacts and switch arms	10	8
Automatic apparatus	17	18
Miscellaneous	25	19
	100	100

The causes of these breakdowns were probably as follows:

	Dynamos. Per Cent. 1906.	Dynamos. Per Cent. 1907.	Motors. Per Cent. 1906.	Motors. Per Cent. 1907.	Starters. Per Cent. 1906.	Starters. Per Cent. 1907.
Accidental	15	8	9	4	22	9
Dirt and neglect	14	25	19	28	11	16
Age and deterioration	21	23	25	23	23	27
Bad work or design	23	21	18	18	9	8
Overloading	0	0	2	1	7	5
Unascertained	27	23	27	26	28	35
	100	100	100	100	100	100

The following interesting and typical examples of breakdowns during the year have been selected from the report:

1. Protected three-phase, alternating-current fifty-horse-power motor, one year old, taking current at 500 volts and running at 750 revolutions per minute. The breakdown can be well described in the inspector's own words. "This motor," he says, "broke down and I examined it today. I found that six of the stator coils have been completely stripped and about fifteen of the rotor coils are badly damaged. I can only suppose that some foreign substance got into the machine when it was running and simply demolished all the coils which were in its path, for the case was full of small bits of copper. The rotor is damaged just in one place, and from the nature of the damage great force has been expended at that point, so I can only surmise that something has caught in the rotor winding and gone round the coils. As is frequent in such cases the driver of the machine swore that the current was switched off and the rotor at rest when the accident occurred, so he evidently knew more about it than he would tell, but I could get nothing further out of him." The motor, as stated above, was protected, but the inspector said it was quite possible for things capable of doing the damage to get in. There is little doubt that something did get in, but what it was was not, and probably will not be, discovered. There is no question of the rotor windings having been lifted by centrifugal force, as the binders were intact.

2. Four-pole, totally enclosed, series-wound eight-horse-power motor, two years old, driving a winch in a shipyard with current at 480 volts; speed, 700 revolutions per minute. The fuse, a No. 16 Standard Wire Gauge, tin wire, having melted, one of the company's inspectors was sent for to examine the motor. He found the solder all around the end connections of the armature conductors partly melted and, on taking out the armature, four coils were seen to be completely burnt out. Wedged into the space between two of the conductors and the end of the core was a piece of cinder which, no doubt, was the cause of the trouble. How it got there in an enclosed motor is a mystery. The only suggestion the writer can make is that the armature must have been set down upon it or rolled over it at some time when taken out and that movement of the conductors while the motor was running had caused it to rub through the cotton covering and short-circuit the coils.

3. Semi-enclosed, two-pole, centre-hung, shunt-wound two-and-one-quarter-horse-power continuous-current motor, taking current at 500 volts, and driving a fan in a smithy at a speed of 2,400 revolutions per minute. According to the statement of the attendant a belt of flame ran around the commutator when he started the motor. When he stopped it he found the remains of two rats wedged between the armature and the frame, but could discover no injury to the conductors. By testing, however, the company's inspector, who had been sent for, found a break in one of the end connections, close to the commutator, which had, no doubt, caused the sparking. Whether one of the rats was accountable for the breakage was uncertain.

4. Two-pole, totally enclosed, shunt-

wound, four-horse-power Lundell motor, taking current at 230 volts, and running at 1,100 revolutions per minute. The company's inspector was sent for because smoke was issuing from the joints of the carcass. He examined it, ran it, and tested the insulation without discovering any fault. He then had it opened and discovered that the smoke had come from the ignition of a quantity of oil, dust and dirt which had accumulated upon the bottom of the circular magnet coil by sparks from the brushes, and that the sparking had been caused by one of the carbon blocks getting jammed in its brush-holder. The insulation of the magnet coil was also slightly charred. This was patched up, the brush-gear put in order, and the motor cleaned and started. Since then it has given no further trouble. This is quite a typical case. Fires inside motors started by the ignition of collections of fluff and dust are not uncommon.

5. Four-pole, shunt-wound, semi-enclosed motor, about two years old, giving eighty horse-power at 500 revolutions per minute with continuous current at 500 volts, and protected by two No. 16 Standard Wire Gauge, copper wires fusing with 332 amperes, or two and one-half times the maximum current supposed to be carried by the machine. The fuse melted and, on examination, two of the armature coils were found burnt. The remaining coils were saturated with oil and very dirty. The insulation of the commutator segments was also burnt close to the spokes through oil and dust settling between the spokes and short-circuiting them. This insulation, instead of being carried up a short distance, say, one-quarter inch or so, between the spokes, ceased at the ends of the bars, leaving very narrow wedge-shaped openings between the edges of the spokes to hold oil and dust. The machine was so damaged by dirt and neglect that the armature had to be entirely rewound, and the commutator rebuilt and reinsulated. It was only accepted for insurance about eleven months previous to the breakdown, and was then in good condition. It seems, however, that it had then just had the benefit of a thorough repair in consequence of a similar breakdown at the end of its first year's work.

6. Two-pole, continuous-current, shunt-wound motor-transformer working in a substation of a lighting supply, receiving forty-four amperes at 1,080 volts and transforming to 110 volts. Normal speed, 470 revolutions per minute. When started from the central station on the evening of the breakdown the armature gained sufficient speed to break one of the steel binders at the high-tension end and spread the conductors until they jammed themselves fast between the pole-pieces. On examination it was found that one end of the shunt winding had slipped out of its terminal. One of the attendants who had cleaned the machine in the morning declared that the wire was then in place, and suggested that it must have been shaken out of the terminal by vibration when the machine was started. It is far more likely that he pulled it out with the duster or waste he was using, for the wire had simply been slipped under the binding screw, and not bent around or over the terminal block. The case is mentioned because the number of shunt wires broken or pulled out of their terminals proves that such wires ought to be better protected and more efficiently secured than they generally are.

7. Four-pole, compound-wound dynamo, three years old, giving ninety amperes at 250 volts when running at 850 revolutions per minute. The commutator contained 153 segments insulated, with one exception, by mica plates. The exception had micanite. The two coils in connection with this segment were burnt out and had to be replaced. The cause was a short-circuit across the micanite insulation, produced by carbon dust and oil which had penetrated into the micanite. The other segments were quite as dirty, but the mica plates between them had kept up the insulation. The company's experience undoubtedly is that pure mica is to be preferred to micanite or made-up mica for insulating commutator bars.

8. Seven-horse-power, three-phase motor of foreign manufacture driving the hoisting winch of an overhead crane with alternating current at 190 volts. The three leads to the slip-rings were fused. On examining the rotor it was found that the core plates had been treaded upon the shaft and a ring shrunk on at each end to hold them. There was no key or feather to prevent them turning. The conductors were led over the ends of the core through a hole in the shaft, which was hollow, and out at the end to the slip-rings. This hole had sharp edges and was not bushed with insulating material. The consequence was that the rotor got loose and rocked upon the shaft, rubbing the insulation of the leads where they entered the shaft and short-circuiting them.

9. Four-pole, shunt-wound, ventilated motor, seven horse-power, fourteen and one-half amperes, 400 volts, 1,000 revolutions per minute, driving machine tools. Fuse when insured, one No. 16 Standard Wire Gauge, tin wire, subsequently replaced by a cartridge "Mordey" fuse of twenty-five amperes. On receipt of a message by telephone that the motor had broken down an inspector was sent to examine it. He found that the armature had been taken out and sent to the maker's works, whither he followed it. There he found that two of the conductors were broken, one close to the commutator lug and the other so close to the core as to necessitate lifting the coil, and as this could not be done without lifting the other coils the repair meant rewinding the armature. He also learned that the makers had been sent for some months before on account of bad sparking, and had then warned the owner that the machine was overloaded. With this information the inspector went back to the owner's works as soon as the armature had been repaired and replaced, and measured the current required to run all the machinery which the motor drove. He found it to be twenty to twenty-one amperes. The owners then admitted that they had added some machines since the insurance was effected, and promised to make inquiries as to the price of an additional motor.

The Railway Signal Association.

The twelfth annual convention of the Railway Signal Association will be held at the New Willard Hotel, Washington, D. C., October 13, 14 and 15.

On October 13 sessions will be held at 10 A. M. and at 2 P. M. The morning session will be devoted to the president's address, the report of the secretary-treasurer, and reports of standing committees. The afternoon session will be devoted to considering amendments to the constitution, and papers on electric interlocking, mechanical interlocking and storage batteries.

On October 14 a session will be held at 9 A. M. to take up a discussion of signal practice, standard design, automatic stops and cab signals, and subjects and definitions.

On October 15 a session will be held at 9 A. M., taking up automatic blocks, rubber-covered wire and manual blocks. The selection of a place for the next annual meeting and the election of officers will be consummated at this session.

LETTERS TO THE EDITOR.

State Branches of the National Electric Light Association.

To the Editor of the Electrical Review:

The editorial in your issue of the nineteenth on the Pennsylvania Electric Association becoming a state branch of the National Electric Light Association I have no doubt was inspired by the best of motives, yet I feel it would form in some minds a wrong impression, and hasten to correct same.

One might gather from reading it that the scope of the state branches of the National Electric Light Association might be restricted, or the policies dictated, by the parent body. Such is not the case. All the individuality of the state association is retained. While all the members of the state branch will be necessarily members of the national association, on the other hand, any member of the national association can be refused admittance to, or expelled from, the state branch.

The centralizing of the clerical work has some economic value, but is of minor importance in affiliating with the national. The real advantage to the state branches will be the co-operation of their committees with those of the national; the use of the greater facilities for data and guidance in preparing papers and carrying on such work as needs influence and superior council. Besides, its acts will have greater prestige if backed up with all the power of the National Electric Light Association.

The national, on the other hand, gets a larger membership, and is fulfilling its mission more thoroughly by keeping closer in touch with the whole industry at large, by closing in a lot of loose ends, becoming the connecting link between all these associations, thus increasing both its power and prestige.

L. H. Conklin.

Connellsville, Pa., September 21.

[And this is exactly what we said, or thought we said. And we are glad to publish Mr. Conklin's letter, so that there will be no misunderstanding.—Ed.]

Symbols for Physical Quantities.

To the Editor of the Electrical Review:

Now that there has been some opportunity for discussing this question, may I be permitted to summarize the arguments that have been raised for and against the creation of new symbols?

The most common objection is, "They are like Chinese characters; we could never remember them." But there will be no necessity to remember them. How many of us can remember what symbol Rankine uses for kinetic energy? Is it not sufficient for us if we see it when we refer to his book? Every considerate writer to-day gives a list of the symbols he uses. If all writers used the same symbols we should soon become familiar with those with which we are most concerned, and for the rest, we could refer to the list just as at present.

Some objectors do not see why the letters we have at present are not sufficient. Let them try to make a list of symbols for the 200 physical quantities for which symbols are wanted. After they have made up a list to satisfy themselves (if such a thing is possible) let them try to convince some one else to adopt that list.

There are about twenty letters such as m for "mass" t for "time," etc., upon which there is almost universal agreement. One or two dozen more stand a fair chance of being agreed upon. Beyond these there is hopeless confusion, simply because all the good letters are exhausted.

As to the difficulty of printing new symbols, it is of interest to know that twenty-five of the leading technical journals of the world published an article containing five new symbols given as examples without any difficulty. Several of them have expressed the view that there is no difficulty from the printer's point of view. The types supplied to them—which, by the way, cost two cents for thirty—were all of one size, and yet each paper used for the text of the article its usual standard type. The publisher of the *Elektrotechnische Zeitschrift* thinks that there would be no difficulty in arranging with a type founder to make matrices, from which all printers could be supplied with type. Each printer would keep in stock those types which commonly occurred in his paper, and could get others on short notice. About thirty new symbols would be sufficient for articles on electrotechnical science.

Two papers have objected that the symbols can not be set up on a linotype machine. It is, however, usual at the present time to set up mathematical expressions by hand.

Several critics have pointed out that the new symbols should be simple and bold in outline, so that they can not be easily mistaken for one another. This, of course, is an important matter to bear in mind.

I agree with M. Galliott that the name of the symbol should be, where possible, the name of the physical unit represented. Where the name of the unit can not be employed, a word of one syllable might be chosen, as for instance, "stroke" for the length of a piston stroke.

Some critics say that the number of symbols required would be too great. As to that, we can make just as many as convenient. The symbol became universal almost as soon as it was printed. Let us have a few more as good as that one; we are badly in need of them.

Jules Walker.

Hale, Cheshire, England, September 19.

The Edison Rate Decision.

To the Editor of the Electrical Review:

In your editorial on the Edison Rate Decision, you say that the Massachusetts Gas and Electric Light Commission has gone squarely on record against the modified Wright demand system used by the company.

I do not interpret the decision this way at all. The recommendations of the board are three:

First, that the company should establish a maximum rate of twelve cents.

Second, that it should not make any special rates in the form of personal discounts.

Third, that it should not make any special rate to municipal customers, as such.

All the company's other rates are tacitly approved, though the hope is expressed that ultimately the maximum rate may be made low enough so that the various long-hour and wholesale discounts made by the company for various classes of service, may no longer be necessary.

The latter, as you will note, is what the lawyers call *obiter dictum,* as with most of the criticisms made by the board on the Wright demand system.

The board states that it is impossible to compute exactly the cost of supplying individual customers, and that it is desirable that all these costs should, for the small customer, be averaged into a uniform rate, but speaks with approval of the differential rates on the Wright demand and wholesale basis, as developing business that enables the rate to the small customer to be lower than it would be if these systems were not in use.

If you will look back through various other decisions of the board you will find that they have been along much the same line; that the board would like to see a uniform flat rate and has in many cases recommended a uniform flat rate as a maximum. Except when recommending a uniform flat rate, as a maximum, the board's remarks have invariably been *obiter dicta* and there are numerous cases on record where the board has clearly recommended differential rates, sometimes on the basis of wholesale and sometimes on the basis of long-hour.

It is obvious that this must be the case. For instance, the Boston arc lights are to-day being supplied at a price of approximately $120 a year for a use of approximately 2,000 kilowatt-hours a year.

On the basis of the twelve-cent rate as recommended by the board for the Boston Edison Company, the Boston Edison Company would be entitled to charge the city of Boston, approximately $240 per year per arc lamp. Can any one imagine the board endorsing such a price for street arc lamps in Boston, or justifying an order for a lower price on anything else than the principle of the Wright demand system?

BOSTON.

September 21.

A New Scale for Incandescent Lamp-Measuring Instruments.

The ingenuity which German manufacturers exercise in their efforts to develop the use of electric light is evidenced by a new scale put on the market by the firm of Nadir, Berlin, says *L'Electricien* (Paris). This scale makes it possible to read directly, in tenths of pfennigs (one pfennig equals one-quarter cent), or even in smaller fractions, the cost price per hour of operating any type of lamp. The same apparatus, which thus gives to the inexperienced consumer more tangible and definite information than any explanation regarding electrical units, also makes it possible to read the consumption in watts and amperes. The standard instrument is applicable to 220-volt circuits, where the current costs ten cents a kilowatt-hour.

Magnetic Club Anniversary.

The twentieth anniversary of the Magnetic Club will be celebrated at the regular fall dinner, to be held at the St. Denis Hotel, New York city, on November 18. On this occasion it is expected that delegates from the Telegraphers' Mutual Benefit Association will be in attendance as guests, as has been the custom for the past fifteen years.

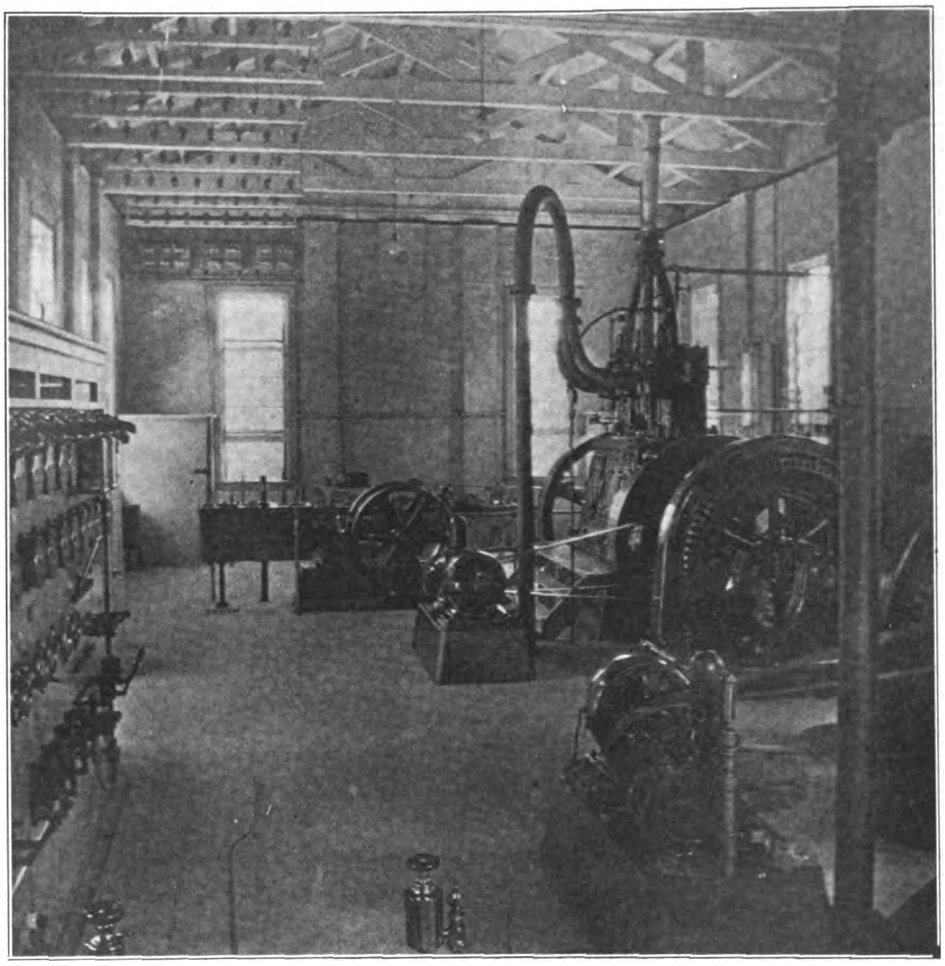
Electric Plant at Coeymans, N. Y.

The Atlantic Light and Power Company, Coeymans, N. Y., was organized in response to a popular demand for better lighting service than that formerly furnished by the Upper Hudson Electric Company. As a municipal plant was not legally possible, the leading citizens of Coeymans, Ravena and New Baltimore organized this company. It has so satisfactorily fulfilled its purpose as to very nearly drive its competitor from the field in these villages (about twelve to fourteen miles south of Albany), and has the moral support of the inhabitants of Coxsackie where the competing plant is located.

The Coeymans plant supplies street and commercial lighting in Coeymans, Ravena and New Baltimore, and lights the station and yards of the West Shore Railroad at Ravena. The street-lighting system consists of over two hundred forty-candle-power tungsten lamps on a series circuit, which are carried on a contract at $20 per lamp per year. The railroad uses twenty-one arcs and 200 incandescents on multiple circuits. The present commercial lighting load is about 200 tungsten lamps, which the company furnishes to consumers at cost, and about 1,500, fifteen-candle-power incandescents. The lighting rate is twelve cents per kilowatt-hour with a sliding scale of discounts.

The power service has not yet been developed as the plant has been in operation only since February 29, 1908. Preparation has been made on the switchboard, however, for a power circuit. The power rate will be from ten cents down to two and one-half cents per kilowatt-hour.

The power plant contains two duplicate eighty-five-kilovolt-ampere sets, making a total capacity of 170 kilovolt-amperes. It is intended, however, that only one set shall be used at a time, the other being kept as a spare. In case of an increase of the load beyond the capacity of one set, duplicate additional sets will be installed. This provision has secured many customers for the concern as it assures continuous service. The fact that the Crocker-Wheeler generators used are easily paralleled obviates the sudden fluctuations which were had with the old service when throwing the load from one generator to another.



ENGINE ROOM, ELECTRIC LIGHT PLANT, COEYMANS, N. Y.

The power-house consists of a brick and cement structure thirty-two feet by sixty-six feet and eighteen feet high at the eaves. The roof is of wood, covered with corrugated iron, and the floor of cement.

The generating sets consist of Crocker-Wheeler generators coupled direct to Diesel oil engines. The engines, each rated at 120 horse-power and having three cylinders, twelve inches by eighteen inches, were built by the American Diesel Engine Company, of New York. They burn crude oil, which is injected into the cylinders by means of compressed air at a pressure of 900 pounds. For this purpose each engine has belted to it an Ingersoll-Rand nine and one-quarter by three by ten two-stage compressor. Cooling water is circulated by a Pyramid four by five pump, belted to each set.

Two 7,500-gallon oil tanks are located about thirty feet from the building. These are buried in the clay soil to exclude water due to sweating. In addition a 10,000-gallon tank is provided at the railroad, from which the oil is carried to the storage tanks in a tank wagon.

A 14,000-gallon cooling tank is installed at the rear of the building. This is of wood, supported on a concrete foundation. The water is delivered as a spray at the top of a series of wooden steps down which it is allowed to drip to the tank.

The generators are thirty-two-pole, eighty-five-kilovolt-ampere, 2,300 - volt, two-phase, sixty-cycle machines, at 225 revolutions per minute. They were built by the Crocker-Wheeler Company, of Ampere, N. J., and are of the same general type as the larger machines built by the company, which operate particularly well in parallel with each other or with machines of other types. The winding of the revolving field consists of strip copper wound on edge, which affords radiating surface for each turn of the winding, thus insuring cool running. The ventilated type of core and housing also insures thorough circulation of air. The use of magnetic wedges in the core slots is a feature of these generators. It permits the use of form-wound and pre-insulated coils and solid pole-shoes.

The exciter belted to each generator is a Crocker-Wheeler Form I, 6.5 kilowatt, compound-wound generator, running at 1,100 revolutions per minute.

The switchboard is composed of six panels of blue Vermont marble, ninety inches high and with a total length of about twelve feet. The panels are Crocker-Wheeler type 12. The first two panels at the left are combined generator and exciter panels. The next two are feeder panels, each containing two single-phase circuits. Of these, one circuit is provided for commercial lighting in each of the villages of New Baltimore, Coeymans and Ravena, and the fourth circuit supplies the railroad lighting. Each of these circuits contains a Crocker-Wheeler single-phase feeder regulator, capable of regulating the voltage of the circuit ten per cent above or below the bus-bar voltage. The fifth panel contains three 150-light series incandescent systems for street lighting, with Wood regulators situated behind the board. Integrating wattmeters are provided on this panel, to check up the cost of the street and commercial lighting.

The pole line is of such height that the wires are suspended above the lines of the telegraph and telephone companies and above the lines of the old lighting company, some of which still remain. All lines are provided with lightning arresters at the switchboard, at the first pole and at various points along the lines. All guy wires are provided with strain insulators to protect pedestrians, and pole transformers are grounded. Street lamps are permanently suspended from the poles on six-foot and eight-foot arms of one-inch pipe, from the ends of which the lamps are insulated by means of glass petticoat insulators in Philadelphia fixtures, with General Electric sockets and receptacles.

The cost of fuel and lubricant for the engines is very low, not exceeding forty gallons of fuel and one and one-half gallons of lubricant per day; the station output being about sixty horse-power for ten hours and very light for the other fourteen hours.

The president of the company is John N. Briggs, of Coeymans, and the consulting engineer for the plant is H. B. Sweet, of Utica, N. Y.

BOOK REVIEW.

"Electrical Contracting." Louis J. Auerbacher. New York. McGraw Publishing Company. Cloth. 156 pages. 5½ by 8½ inches. Illustrated. Furnished by the Electrical Review for $2.

In this book the author has gathered together a goodly amount of very practical information, especially for the wireman and contractor. While it is a good thing to be possessed of considerable technical information in undertaking to carry out the work on the excellent lines which the author has laid down, the instruction is given in so clear and lucid a manner that the book will be found of great value to the man on the street who is desirous of making a minor installation. Mr. Auerbacher has had a great deal of experience in the field as a workman, foreman and employer, and his capability is reflected in the presentation which he has made in the present volume.

Meeting of the American Association of Electric Motor Manufacturers.

The fall meeting of the American Association of Electric Motor Manufacturers took place at Frontenac, Thousand Islands, N. Y., September 9, 10 and 11. During the meeting the following papers were presented, with a view to bringing forth discussion, thus enabling the various committees to incorporate in their reports recommendations for the adoption of uniform practices in the manufacture of electric motors, to the end that the highest quality of electric motors may be manufactured by the members of this association:

"Ratings and Guarantees on Direct-Current Motors," by J. M. Hipple. Presented by W. T. Hensley.

"Ratings and Guarantees on Alternating-Current Motors," by C. S. Reno.

"Ratings and Guarantees on Variable-Speed Motors for Elevator Service," by W. J. Warder, Jr.

"Freight Traffic," by W. B. Everest.

The various committees appointed at the former meeting have collected considerable information of value for dissemination among the members of the association.

At this meeting W. H. Tapley was regularly installed as the permanent secretary of the association, J. C. McQuiston, who has acted as temporary secretary since the formation of the association, retiring.

The association has provided permanent headquarters in the Engineering Societies Building, 29 West Thirty-ninth street, New York.

The next meeting will be held about the middle of January, 1909.

A considerable amount of business was transacted during the three days of the meeting, but time was found, however, on Thursday afternoon, September 10, for recreation, there being three contests: one for golfing, one for bowling, and the third for fishing. The golfing trophy, a cup, was won by Charles Robbins, of Pittsburg; the bowling prize, a silver cup, was won by W. S. Kemp, of Brookline, Mass. The prize for the largest fish caught—a rod, line and reel—was captured by F. M. Kimball, of Boston.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

MEXICAN TELEGRAPH COMPANY.

The Mexican Telegraph Company reports for the quarter ended September 30 (partly estimated) as follows: Traffic receipts, $160,000; operating expenses, $42,000; net earnings. $118,000; interest accrued, $26,000; total income, $144,000; less Mexican Government's proportion of earnings for current quarter, $7,500; balance, $136,500; to provide for October dividend, $71,752; surplus, $64,748; previous surplus, $2,559,850; total surplus, $2,624,598.

CENTRAL & SOUTH AMERICAN TELEGRAPH COMPANY.

The Central & South American Telegraph Company reports for the quarter ended September 30 (partly estimated) as follows: Traffic receipts, $365,000; operating expenses, $165,000; net earnings, $200,000; interest accrued, $4,500; total income, $204,500; amount required for October dividend, $143,565; surplus, $60,935; previous surplus, $1,279,133; total surplus, $1,340,068.

BROOKLYN RAPID TRANSIT.

Gross earnings of the Brooklyn Rapid Transit Company since the beginning of the new fiscal year on July 1, show a decline of between six and seven per cent compared with the same period last year. Comparison is being made, however, with record-breaking earnings, the September quarter in 1907 being the biggest in the company's history. Practically all of the falling off in gross has been in beach traffic, upon which the company has never been able to make any show of net earnings, so that net earnings for the current quarter are not likely to fall materially behind those of last year.

MINNEAPOLIS GENERAL ELECTRIC COMPANY.

The report of the Minneapolis (Minn.) General Electric Company for the month of July and twelve months ended July 31, is as follows: July gross, $73,889; expenses, $32,025; July net, $41,864; charges and taxes, $32,400; July surplus, $9,464, as compared with $10,666 for July, 1907. Twelve months' gross, $961,506; expenses, $435,638; twelve months' net, $525,868; charges, $354,422; twelve months' surplus, $171,446, as against $219,518 for the preceding year.

SEATTLE ELECTRIC COMPANY.

The Seattle Electric Company, of Seattle, Wash., reports as follows for the month of July and twelve months ended July 31: July gross, $366,481; expenses, $209,950; July net, $156,531; charges and taxes, $87,515; balance, $69,016; sinking fund, $7,344; surplus, $61,672, as compared with $77,205 for the same period of 1907. Twelve months' gross, $4,381,787; expenses, $2,592,139; twelve months' net, $1,789,648; charges and taxes, $944,087; balance, $845,561; sinking fund, $88,451; surplus, $757,110, against $784,517 for the preceding year.

GALVESTON-HOUSTON ELECTRIC COMPANY.

The report of the Galveston-Houston (Tex.) Electric Company for the month of July and twelve months ended July 31, shows as follows: July gross, $93,374; expenses, $52,004; July net, $41,370; charges and taxes, $17,476; balance, $23,894; sinking fund, $2,609; July surplus, $21,285, compared with $26,968 for July, 1907. Twelve months' gross, $1,063,622; expenses, $624,497; twelve months' net, $439,125; charges and taxes, $208,063; balance, $231,062; sinking fund, $31,305; twelve months' surplus, $199,757. This compares with a surplus of $190,796 for the preceding year.

RAILWAYS COMPANY GENERAL.

The Railways Company General (New York) annual report for the fiscal year ended June 30, 1908, is as follows: Total income, $167,071; net profit, $5,679; previous surplus, $280,203; net surplus, $285,882, comparing with $280,203 for the preceding year.

The balance sheet as of June 30, 1908, is as follows: Assets—Cash, $37,874; due from subsidiary companies, $292; bonds of subsidiary companies and capital stock subsidiary companies, $675,754; other securities owned, $155,818; furniture, fixtures and sundry securities, $507; notes receivable, $128,136; total, $998,382. Liabilities—Capital stock, $700,000; accounts receivable, $12,500; net surplus, $285,883.

President T. D. Rhodes says: "While the showing would seem to compare unfavorably with that of previous years the board feels that under the financial conditions prevailing during the period covered, the company is most fortunate in the actual returns made."

TOLEDO RAILWAYS AND LIGHT.

The Toledo (Ohio) Railways and Light Company's report for August and eight months compares as follows: August gross, $212,318; expenses, $113,811; August net, $98,449; other income, $136; total income, $98,585; charges and taxes, $71,879; August surplus, $26,706, comparing with $34,930 for August, 1907. Eight months' gross, $1,641,930; expenses, $907,923; eight months' net, $734,007; other income, $3,011; total income, $737,018; charges and taxes, $563,766; eight months' surplus, $173,252, as against $198,248 for 1907.

NORTHWESTERN ELEVATED RAILROAD.

The Northwestern Elevated Railroad Company's report for the year ended June 30 shows as follows: Gross, $2,463,188; expenses, $965,118; net, $1,498,070; charges, taxes, etc., $1,147,183; surplus, $350,887, which compares with $347,578 in 1907 and $280,499 in 1906, and is equal to seven per cent earned on the $5,000,000 preferred stock. The rate of operating expenses to earnings (excluding loop net earnings) was 50.22 per cent. The ratio of operating expenses, loop account and taxes to earnings (excluding loop net earnings) was 66.64 per cent. President Starring, of the Northwestern Elevated, tells of the satisfactory purchase of forty coaches now in service and twenty combination motor-cars ordered from the Pullman Company for this fall's delivery. The company's total capacity is 28,800 horse-power, or sixty-seven per cent increase. The Ravenswood extension is completed and a satisfactory contract made with the St. Paul, under Chicago and Evanston ordinances, to operate the Evanston division for thirty-seven years. The Sunday business shows big gains. Total passengers carried for the year numbered 37,419,286, a daily average of 102,238. The average daily increase was 17,245, or 20.29 per cent.

Galvanic Battery.

A recent patent, says *Centralblatt für Accumulatoren und Galvanotechnik*, was issued for a galvanic battery in which an increase of capacity and a decrease of internal resistance is attained by replacing the negative electrode by metal shavings placed in closest proximity to the positive electrode. The latter is surrounded in the usual way by a layer of powdered or kerneled material for depolarization. A ring of zinc with a zinc strip, forming the pole, is embedded in zinc shavings. The battery is filled with a solution of NaCl, which furnishes in the chemical process a soluble zinc salt, so that a bright metal surface is always maintained.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Copper Production and Industry in Russia.

The copper production of Russia in the year 1907 amounted to 962,354 poods (one pood being equal to thirty-six pounds) and was greater than that of any preceding year. In 1906 the production was 639,000 poods.

The increase was principally brought about by the mines in the Urals, which almost doubled their output; in fact, from 260,288 poods in 1906 it rose to 436,918 poods in 1907. The next largest producers were the mines in the Altai and Caucasus Mountains and in the Kirghese steppes.

Taking into account the import, the consumption of copper in Russia during 1907 may be estimated as 1,122,000 poods. The price fell continually during the whole year; from twenty-three rubles a pood (for copper ingots) at the beginning of January it descended to fourteen rubles in December.—*Translated and abstracted from L'Elettricista (Rome), August 1.*

Thomshavn to Lokken Electric Railway.

The first single-phase line in Norway, running between Thomshavn and Lokken, is described by A. C. Kelly. The railway is situated about twenty miles west of Trondhjem, from which town a steamer now runs twice daily in connection with the railway. The line runs inland a distance of about seventeen miles. The water-power station is located at Skjenald Fossen. This station supplies power for lighting to Thomshavn and the villages on the line of the railway, to the mining machinery at Lokken, and to the railway itself. The railway load is supplied from a substation at Thomshavn, which contains a motor-generator plant for transforming the 15,000-volt, fifty-cycle, three-phase supply to 6,600-volt, twenty-five-cycle, single-phase current, which is delivered direct to the overhead trolley wire. The Westinghouse single catenary system of trolley suspension is employed, carried on bracket arms on wooden poles. The rolling stock at present consists of three locomotives, one saloon motor-car, four passenger vehicles and twenty-one freight vehicles. Each locomotive weighs twenty tons and carries four motors mounted on two bogies. The high-tension current is collected by a pantograph bow collector mounted on the roof of the locomotive, and passes by an insulated cable to an automatic circuit-breaker, and then to the transformer, which is suspended inside of the cab. The whole of the high-tension apparatus is enclosed in an earthed metal screen. Several tappings are brought out from the low-tension end of the transformer and are connected to the two hand controllers, one at each end of the cab. The four motors are arranged permanently in two groups, with two motors in series in each group. The motors are of the Westinghouse single-phase, series-compensated type, having a rating of forty horse-power for one hour. The pinions have fourteen teeth, and the gear wheels seventy-six teeth, the diameter of the driving wheels being thirty-three inches. The locomotives are capable of exerting a tractive effort of 6,500 pounds at ten miles per hour and a maximum tractive effort at starting of 8,000 pounds. The saloon motor-car, which has been provided for the use of the directors of the company, is a fine specimen of the car-builders' art. It is thirty-nine feet four inches over the headstocks, and eight feet six inches wide at the waist rail, and weighs, in running order, 22.8 tons. The interior is divided into a vestibule and driver's compartment at each end, and two saloon compartments, separated from each other by a short passage, from which a lavatory opens. One saloon compartment is provided with a writing table and swinging arm-chair, and the other is furnished with cross-seats and a central gangway. The body is framed with oak and sheathed with teak. The floor has been made as sound-proof as possible. The body is carried on a substantial underframe of rolled steel which, in turn, is supported by two swing bolster trucks. One of these trucks is equipped with two forty-horse-power motors similar to those used on the locomotives. The interior of the car is upholstered throughout in crimson buffalo hide, the woodwork being of special figured oak. The ceiling is covered with panels of artistic design relieved by narrow gold lines and delicately tinted border. The floor, which is made up of two thicknesses of tongued pine, is covered with felt and cork carpet, on top of which is laid a heavy Axminster carpet. Electric heaters and electric lighting are, of course, provided throughout the car. The car was built by the United Electric Car Company, Limited, of Preston, England.—*Abstracted from the Tramway and Railway World (London), September 3.*

A New Variable-Speed Single-Phase Motor with High Starting Torque.

A modification of the repulsion type of single-phase commutator motor has been developed by H. C. E. Jacoby for fulfilling the requirements where a motor has to have a variable speed, together with a high starting torque. In this motor commutation difficulties are reduced to a minimum by eliminating, in a simple manner, the chief source of commutator troubles inherent with this type of motor. When an ordinary continuous-current winding connected to a commutator is employed in alternating-current work the coil undergoing commutation is in such a position that it encloses the whole magnetic flux, which, being alternating in character, introduces a considerable electromotive force in the short-circuited coil. This electromotive force is out of phase with the main rotor current and causes large surging currents to flow in the coil. Attempts have been made to reduce this short-circuit current by inserting resistances between the windings and commutator bars. In order to obtain sparkless commutation it is necessary that an electromotive force shall be provided in the short-circuited coil of just sufficient value to reverse the current. This is generally done in continuous-current motors by the use of carbon brushes, which, by introducing a gradually increasing contact resistance at the leaving bar, produce a drop of potential across the contact. By a suitable choice of carbons and constants excellent results are secured. In the new motor the rotor winding is so arranged that the coil short-circuited by the brush encloses little or no magnetic flux—that is, it is parallel to the transformer flux. The consequence is that commutation is brought under similar conditions as obtain in continuous-current motors. This is accomplished, furthermore, without complicated connections. The rotor coils are wound across a particular fractional pitch, and the brushes are placed in a position so that the short-circuited coils are parallel to the transformer flux. With this arrangement there are zones on the rotor in which the current flows in opposing directions in adjacent wires. At first sight it would appear that this method of winding would result in considerable loss of torque, and if it were employed on a continuous-current motor the resulting torque with equal currents would be less than half what it would be with an ordinary winding. In this case, however, it is claimed that this mode of winding actually increases the resulting torque. In the first case, by eliminating the heavy currents in the short-circuited coils, a troublesome source of back torque is eliminated. The effects of the currents in the rotor conductors causes a displacement in phase of the magnetic flux in a portion only of the polar face, and to obtain the best results it is necessary that the coils doing motor work should be designed with shortened step to suit this. It is claimed that with this winding equally good commutation is obtained with any brush position between maximum and minimum torque. This makes it possible to govern the speed of the motor by shifting the brush position only. The fact that the friction of the brushes causes the brush rocker to tend to revolve in the direction of rotation makes it necessary to exert only sufficient force to overcome the friction of the brushes, and the slightest deviation from this amount causes the brushes to advance or recede. It is stated that tests taken on a five-horse-power motor at 900 revolutions per minute, on a single-phase circuit, operating at 200 volts, fifty cycles, showed the machine to have a full-load efficiency of eighty-five per cent, and a half-load efficiency of seventy-seven per cent; a power-factor of 0.85, and a starting torque of one pound per 100 volt-amperes at one foot radius.—*Abstracted from Electrical Engineering (London), September* 10.

A Rotary Converter for 2,000 Amperes.

The rotary converter does not enjoy the same favor in Europe as in America; nevertheless it is superior to the motor-generator from the triple point of view of efficiency, expense of maintenance and cost price. On the other hand, it possesses the advantages and disadvantages of synchronous motors without, however, quite equaling the latter in regard to the increase of the power-factor by the over-excitation of the electromagnets. The almost general adoption of a frequency of fifty periods per second in alternating-current lines, which is a little high for a rotary converter, is perhaps the reason for the limited success of these machines. However, in view of the scarcity of actual applications, the details of two identical rotary converters installed recently by the Felten-Guilleaume-Lahmeyer Company in the works of the Chemische Industrie Gesellschaft may be of interest. These two machines, each of 800 kilowatts, have eight poles and a regular velocity of 750 revolutions per minute, which corresponds to a frequency of fifty periods per second. They are fed by three-phase, alternating-current at seventy to eighty volts, and deliver on the direct-current side 2,000 amperes at 110 volts. The movable secondary is 310 millimetres in length and 700 millimetres in diameter. The continuous current is collected by eight rows of six brushes bearing on a commutator 450 millimetres in diameter and 400 millimetres in width, consisting of 168 segments. The position of the brushes is regulated once for all, as the machine works without sparking under all loads. The arrangement for supplying current on the alternating side consists of three copper rings, 100 millimetres wide and 400 millimetres in diameter, on each of which bear nine pairs of brushes. The winding of the secondary is comprised of 168 coils arranged in slots containing four conductors each. The stationary indicator carries eight poles with massive extensions, which are the seat of parasitic currents, having the effect of killing the pendulum movement (pumping) when the converters work in parallel. This construction is simpler and cheaper and just as effective as providing the laminated pole-pieces with compensating windings. It need scarcely be stated that the pole extensions are ventilated in order to prevent overheating. Two cylindrical frames surround the machine completely. Its ventilation and cooling are assured by a ring of vanes fastened on the shaft between the collector rings and the secondary. Fresh air is drawn in at the height of the rings, traverses the converter and is finally blown out over the commutator and brushes. It is well known that, although it is not impossible to start the converter by the alternating current, it is undesirable to do so on account of the heavy flow of current thereby produced, and for this reason an auxiliary asynchronous motor of fifteen horse-power has been arranged at the end of the shaft for starting the machine. It has only six poles, in order to be able to bring the converter to the speed of synchronism in spite of the slip, and is itself started by means of a regulatable resistance in the primary circuit fed by three-phase current at 220 volts from a special transformer.—*Translated and abstracted from L'Electricien (Paris), September* 12.

The Senlecq-Tival Method of Phototelegraphy.

A method of transmitting photographs to a distance has been introduced by Messrs. Senlecq and Tival. This method is distinguished from those of Korn, Carbonelle and Belin by the fact that the actual transmission is a matter of a few seconds instead of thirty or more minutes. The Senlecq-Tival process starts with a bichromate gelatine photograph. This is impregnated with a metallic powder in such a way that the variations of light and shade in the picture correspond with variations in electric resistance of the conducting surface of the picture. A variable resistance is made to cause the current from a constant pressure local battery to vary. These current variations are recorded magnetically on a steel wire, as in a telegraphone. The magnetic record can then be stored away for any desired length of time, and can be employed to reproduce the current variations in a suitable circuit when required. The speed at which the magnetic picture on the steel wire can be transmitted is considerably greater than that at which it can be impressed on the wire in the first case. The receiving instrument consists essentially of a sensitive galvanometer, the deflections of which are magnified by a lever arrangement. The galvanometer actuates a small, thin film screen, which is shaded off from complete opacity to complete transparency by a microphotographic process. In this way the light falling on a rotating disc from a Nernst lamp is varied in intensity in accordance with the deflection of the galvanometer. The disc through which the light passes is perforated with holes lying on a spiral and running from the edge of the disc toward the centre. If the disc in the receiving station rotates synchronously with the telephone drum in the transmitting station, the variations in illumination finally received on a photographic plate correspond with those in the original photograph. It is not stated whether any actual working results have been obtained with this process. It is claimed, however, that if it were possible to reduce the time of transmission to, say, one-tenth of a second, owing to the persistence of vision it would be possible to dispense with the photographic fixing of the received picture, and to view the picture direct on the screen while it was being produced by the rapidly moving spot.—*Abstracted from the Electrical Review (London), September* 7.

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

The Moloney Variable-Voltage Transformer.

The accompanying illustration shows a practical variable-voltage transformer manufactured by the Moloney Electric Company, St. Louis, Mo. This instrument fills a long-felt want in the electrical world, and was designed to meet the demands for a transformer of this kind. The transformer has two rotary dials, one of which increases or decreases the voltage in ten-volt steps. The other dial increases or decreases the voltage in one-volt steps. With this arrangement any voltage from one volt to 150 volts can be secured in one-volt steps.

This type of transformer can be used on the primary (low-tension side) of a high-tension transformer, and will give an increase or decrease of voltage on the high-tension secondary according to the ratio of the high-tension transformer.

Moloney Variable-Voltage Transformer.

This type of variable-voltage transformer is now being used by the largest laboratories in the country, and is a necessary auxiliary to the equipment of every central station using alternating current. It is an almost indispensable aid in properly testing lamps, transformers, meters, cables, etc.

The Columbia Meter.

The Columbia Meter Company, Indianapolis, Ind., has placed on the market an integrating wattmeter, an illustration of which is shown herewith. This meter is of the motor class, being equipped with commutator and brushes. All parts are made by tools, rendering each interchangeable, and giving a light, stiff construction and a good appearance to the meter. The armature is of the open-coil type, having three coils of the same size and shape, symmetrically arranged around the shaft and connected with a three-part commutator. The full current flows through the coils, giving the full effect of the shunt current.

Owing to the small number of commutator segments, a considerable reduction of commutator diameter and brush friction is secured.

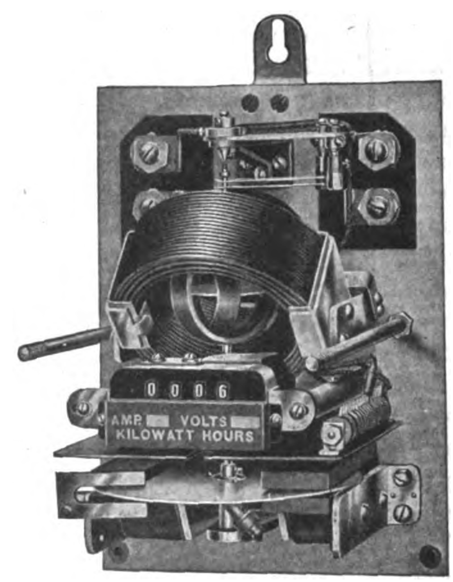
The meter has one series coil, which is placed in an inclined relation with the armature, giving a symmetrical proportion and design. The shunt resistance is a small spool on one side of the meter, easy of inspection and accessible for adjustment or repair. The shunt loss is about two watts at 100 volts.

The two damping magnets are placed at the bottom of the meter, and are interchangeable, and may be taken off and replaced in a few seconds, always going back in the same position. The damping magnets are not moved in calibrating, but a light and easily adjustable armature regulates the damping by shunting more or less of the magnetic flux around the disc. These magnets are protected by a light iron shield between them and the series coil.

The meter is provided with cyclometer counting register, reading in direct kilowatt-hours. The compensating coil is stationary and is regulated by a small rheostat on one side of the meter. The meter has a removable pivot of a grade of steel which experiment has proved to affect the jewel very slightly.

The brushes are of wire, and the brush-holders are easily detachable and in a position for easy inspection and adjustment.

In order that the meter may be sensitive and accurate on low load, it is overcompensated by the compounding coil, made to run fast on low load. If an accuracy of three per cent is desired on fifty watts, the meter is adjusted three per cent fast, thus giving the necessary accuracy as desired. When in service, as the friction increases by long-continued use, the meter will correct itself to a certain extent and show a better agreement between the constants at high and low loads. The adjustment is made by an iron screw, which is magnetized by contact with one of the damping magnets. Three iron studs, fastened to the damping disc, are attracted more or less by the magnetized iron screw. If the screw is adjusted so that a balance is obtained between the rotation of the disc by pressure only, when over-compensated, and the attraction of the magnetized iron screw and studs on the disc is effective, the meter will not rotate, but will start on the smallest load put on it, depending on the adjustment of the screw. This leaves the meter in a very sensitive condition.



Type A.B. Columbia Meter, High-Torque Form for Large Sizes Only.

With the meter so adjusted, it will run fast on low load, and this over-speed can be made of any percentage by the screw adjustment.

Foreign Trade Opportunities.

The Bureau of Manufactures, Washington, D. C., announces the following foreign trade opportunities:

Bids will be received until November 2, by the Direccion General de los Ferrocarriles del Estado, San Eugenio, Chile, for the supply of three 300-kilowatt generators and other equipment for a 900-kilowatt station.

The Ministry of the Interior, Cairo, Egypt, will receive bids until October 29 for the necessary equipment for the installation of electric light in the town of Zagazig. A guaranty equal to ten per cent of the amount of the bid will be required.

The Directoria Gerál de Obras e Viação, Rio de Janeiro, Brazil, will receive bids until October 14 for the supply of material and for construction work upon the Oeste de Minas Railway. In addition to the railway construction work there will be the erection of buildings and offices and the installation of the telegraph line, and the supply of machinery, motors, turntables, etc. A deposit will be required with tenders on this project.

A New Twenty-five-Watt Tungsten Lamp.

The accompanying illustration shows the latest addition to the line of tungsten incandescent lamps for standard lighting circuits (100 to 125 volts) that is being placed on the market by the General Electric Company. This is a twenty-five-watt, one to one-and-one-quarter-watts-per-candle lamp made in a practically identical bulb to that used for the ordinary sixteen-candle-power carbon lamp. The illustration shows the exact size of the lamp, which has the same diameter and base and approximately the same length as the familiar sixteen-candle-power unit.

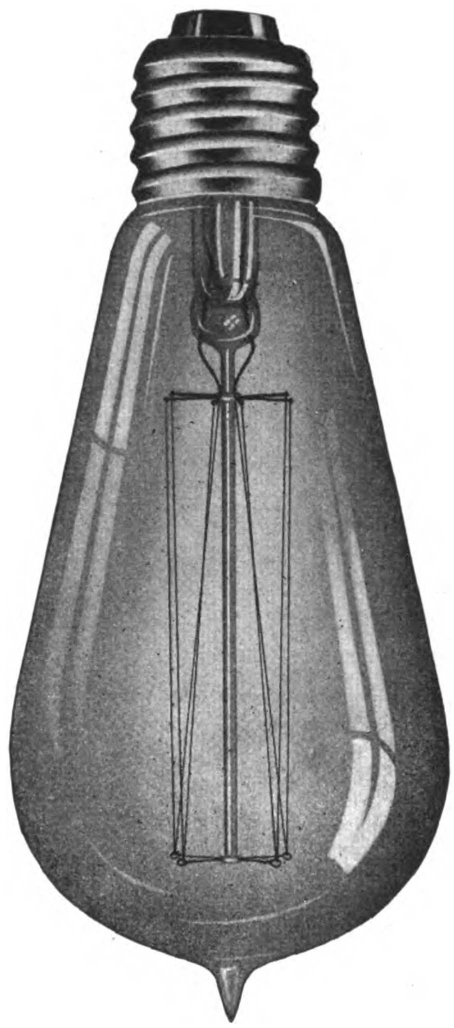
This lamp will burn in any position and its size adapts it for use in any shade or fixture suitable for the sixteen-candle-power carbon lamp. It can be substituted, therefore, lamp for lamp, in all present installations.

At one and one-quarter watts per candle the twenty-five-watt lamp gives twenty candle-power or twenty-five per cent more light than the ordinary sixteen-candle-power lamp. The energy consumed is one-half that of the best sixteen-candle-power carbon lamp and considerably less than one-half the energy consumed by a sixteen-candle-power carbon lamp of similar life—800 hours.

The General Electric Company, as previously announced, has been greatly increasing its manufacturing facilities and is now prepared to manufacture this lamp, together with the forty, sixty, 100 and 250-watt lamps, at the rate of 35,000 lamps total output per day.

Ample stocks of the larger lamps are carried at the main lamp sales office in Harrison, N. J., and at the various local sales offices throughout the country. The stock of the new twenty-five-watt tungsten is at present somewhat limited, but the factory capacity is ample to maintain a reasonable delivery on all ordinary orders.

As the lamp will burn in any position and can be substituted in the regular course of renewals, it will undoubtedly find a large market among isolated plants with the accompanying saving in the coal bill and the opportunity of doubling the number of units and nearly trebling the candle-power with the same equipment.



Twenty-five-Watt Tungsten Lamp.

It should also be gradually introduced on the circuits of central stations as rapidly as customers can be educated to appreciate its advantages.

Standard Tungsten Low-Voltage Lamps for Battery Service, and Tungsten Miniature Lamps.

The Buckeye Electric Company, Cleveland, Ohio, has developed a line of standard tungsten low-voltage lamps for battery service and tungsten miniature lamps for industrial and decorative service. The advantages of these lamps over the carbon-filament types of miniature and low-voltage lamps are not generally understood. About sixteen types are now standardized and the line is rapidly being increased.

These low-voltage tungsten-filament lamps are peculiarly adaptable to automobile and motor-boat service. They are safer, cleaner, more economical and operate more conveniently than either oil or gas lamps, which have had a monopoly of this field. A number of automobiles equipped with the new lamps have demonstrated that the latter give a large volume of light just where illumination is most needed. They are being used with great satisfaction for headlights, side lights and tail lights. These lamps are operated on ignition storage batteries, on low-tension ignition magnetoes or ignition generators. There is very little cost involved in changing over from the gas lamps or oil lamps to the use of the electric lamps. The lamps are used with special parabolic reflectors, which will give any required distribution.

For automobile and motor-boat work the six-volt lamp is generally the standard. Four-volt and eight-volt lamps are giving satisfaction, and these lamps can be secured in sizes ranging from two to twenty-four candle-power. The lamps operate at approximately one watt per candle.

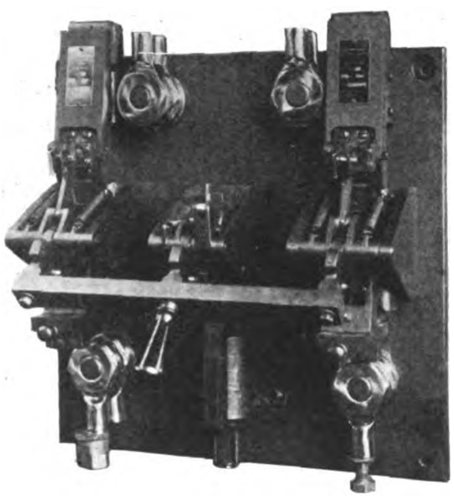
These lamps are also adaptable to train-lighting service, and effect a saving of two-thirds of the current, the best results being obtained with lamps operating on thirty-volt circuits. The breakage is not any greater than that involved with carbon-filament lamps when the thirty-volt sizes are used. Train-lighting lamps are being designed in various types in sizes from twelve to forty-eight candle-power, and in bulbs from one and one-half inches in diameter to three inches in diameter, operating at from one to one and one-quarter watts per candle.

For dental and medical use the low-candle-power miniature tungsten lamps present an entirely new outlook to the operator. It will be hard to secure a better proposition for the dentist or medical practitioner, as these lamps may be operated on dry batteries or small storage batteries, and burn approximately three times as long on a dry battery as a carbon lamp of equal candle-power. The tungsten lamps also operating at lower temperature are decidedly advantageous in dental and medical work.

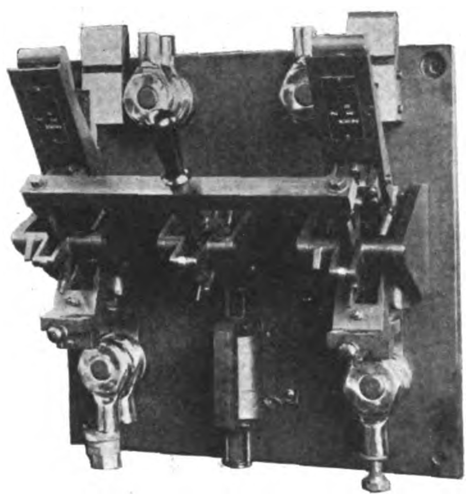
The tungsten miniature lamps, especially in the low-voltage forms, are adaptable to, and will be largely used for, pocket flashlights, for decorative theatrical work, and for Christmas-tree decorations and other novelties.

Special Application of Standard Circuit-Breakers.

In the development of new applications of machinery of various kinds conditions often arise which call for special apparatus or certain applications of old apparatus. Standard apparatus, if properly designed, can be readily adapted to suit these special conditions, with slight changes, and the better the design the more special applications it will fit in on. A notable example of this is shown in a recent application of circuit-breakers, illustrations of which are shown herewith. In this case a large mining company desired a circuit-breaker which would open the circuit of a motor on overload, which could also be opened from a distance by the operator at the machine and which could absolutely be held open by the operator at the machine regardless of the man in charge of the motor. Inasmuch as an absolute interlocking of the machinery was necessary, no chances could be taken of the motor being started when men were working about it.



Circuit-Breaker in Closed Position.



Circuit-Breaker in Open Position.

The illustrations show this breaker in the open and closed positions and illustrate clearly the flexibility of the standard design of the type "CC" circuit-breaker, manufactured by the Westinghouse Electric and Manufacturing Company. This breaker consists of two single-pole breakers and a dummy pole, all closed by the same handle. Each of the single-pole breakers is equipped with an overload coil and the operation of either overload coil opens the breaker, as in the standard type "CC" design. In addition, the breakers can be instantly opened by throwing the handle up. This is a regular feature in the standard design.

In addition to these two overload coils there is placed on the dummy pole a shunt-tripping coil suitable to be left in circuit continuously. Upon closing the circuit through this shunt-closing coil, the middle pole is tripped out and this in turn trips out both of the active poles, thus opening the breaker. In addition to this the handle is locked down by an auxiliary latch in such a way that it can not be closed down until current is taken off the shunt-tripping coil, allowing the core to drop. It is thus impossible for any one to close the circuit-breaker so long as this coil is energized.

In the particular applications small knife-switches were placed at various points, each switch closing the circuit through this shunt-tripping coil. Whenever it is desired to stop the machine and hold it in a stationary position, one of these small switches is thrown in, which immediately opens the breaker and locks it permanently open until the line switch is opened. The breaker is controlled entirely from alternating-current circuits, no direct current being necessary, and it operates large three-phase motors, opening two legs of the three-phase circuit. The breaker is adapted for mounting directly on the wall, the connections being on the face of the panel.

Many other attachments and special applications of this breaker, to satisfy various special requirements, have been developed.

Trigonometric Slide Rule.

M. J. Eichhorn, an electrical engineer, of 5,759 Aberdeen street, Chicago, Ill., has developed a slide rule for solving the various trigonometric functions involved in plane trigonometry. This slide rule is applicable to both the law of cosines and the law of tangents, and other logarithmetrical functions involving the unknown side of a triangle when two sides and the included angle are given.

Two New Pass & Seymour Specialties.

The accompanying illustrations show two new devices placed on the market by Pass & Seymour, Incorporated, Solvay, N. Y. Fig. 1 shows the No. 3010 feed-through switch. This designation comes from the fact that the cord passes through the switch. The uses for such a switch are numerous, as oftentimes in certain work, such as connecting up small sewing-machine motors, stereopticons, heating devices, etc., it is desirable to connect a switch into the cord circuit instead of placing the switch at the end of the cord or using a wall switch. The device is wired by simply passing the cord into the upper bushing, connecting one wire to the terminals, and passing the cord out through the lower bushing. Only one wire is cut, the other passing straight through. This is a National Code device.

Fig. 1.—P. & S. Feed-Through Switch.

Fig. 2.—P. & S. All-Metal Key Socket.

Fig. 2 shows the No. 460 socket. This is equipped with an all-metal key, the mandrel at all times being "dead." The demand for this socket comes principally from the manufacturers of fixtures, portables and similar devices where it is desired to have a socket with a key to match the finish of the fixture. Any "P. & S." brass-shell socket or receptacle may be equipped with this key, for which a slight additional charge is made.

Current Electrical News

DOMESTIC AND EXPORT.

CAROLINA POWER AND LIGHT COMPANY FILES MORTGAGE—A mortgage from the Carolina Power and Light Company, of North Carolina, to the Standard Trust Company, of New York, has been filed in the office of the clerk of the Superior Court. The board of directors of the Carolina Power and Light Company has authorized the issue of bonds aggregating $5,000,000, payable August 1, 1938, each of said bonds to be of the principal amount of either $500 or $1,000, as the mortgagees may from time to time determine, and all of said bonds to bear interest, payable semi-annually, at the rate of five per cent per annum. This mortgage is signed by John D. Mortimer, vice-president of the Carolina Power and Light Company, and by L. L. Stanton, vice-president of the Standard Trust Company.

LONG ACRE ELECTRIC LIGHT AND POWER COMPANY APPLIES FOR REHEARING OF PRIOR APPLICATION ON STOCK ISSUE—The New York State Public Service Commission has received an application from the Long Acre Electric Light and Power Company for a rehearing on its prior application for permission to issue $10,000,000 preferred stock and $50,000,000 in mortgage bonds which was denied by the commission last June after a series of hearings. The petition for a rehearing is signed by John C. Sheehan and Graham & L'Amoreaux, attorneys for the company. It presents twenty reasons for asking for a rehearing. The last reason is an allegation that the action of the commission is null and void for the reason that the Public Service Commission law was unconstitutional. The commission has taken the matter under advice.

NEVADA-CALIFORNIA POWER COMPANY EXTENDING ITS SYSTEM—By the middle of October the third plant to be installed by the Nevada-California Power Company at Bishop Creek, Nev., will be ready for operation. This third plant has a capacity of 6,000 horse-power, which will make the total capacity of the company 17,000 horse-power. This will be ample for the districts of Bishop, Goldfield, Tonopah, Silver Peak, Millers and Rhyolite. The new mill of the Consolidated Mines Company at Goldfield will require from 700 to 800 horse-power and there are other projects in view which indicate that the company's increased capacity will be fully utilized. Next spring the company expects to equip still another plant with a capacity of 6,000 horse-power, and it is not improbable that the light and power system will be extended into Manhattan, Round Mountain and Hornsilver this fall.

MEXICAN ELECTRICAL NOTES—A contract has been closed by Manuel Cuesta Gallardo, of Guadalajara, with the Siemens-Schuckertwerke, of Berlin, for $7,500,000 of electrical machinery. The contract carries the guarantee of the Mexican Government. This was possible under the new law providing for the payment of subsidies for the irrigation of lands and the establishment of a bank for the encouragement of irrigation works and agricultural development. Mr. Cuesta expects to irrigate from 200,000 to 300,000 hectares of land with water from Lake Chapala. Current is to be supplied to the city of Guadalajara and the properties of the Amparo Mining Company by July, 1909. The first hydroelectric plant will be installed by the Berlin concern near the Totolotlan bridge on the Santiago River, about fifteen miles from Guadalajara, where the necessary hydraulic works have been completed. Two turbines, each of 4,200 horse-power, will be put in. It is estimated that the capacity of this plant can be raised to 11,000 horse-power if desired. As soon as the Totolotlan plant is completed work will be finished on the second hydroelectric plant in the cañon of the Santiago River, some distance above the Las Juntas plant of the Compañia de Tranvias, Luz y Fuerza de Guadalajara. In connection with this installation there will be a canal twenty-four kilometres long, nine metres wide and three metres deep, and a fall of 400 metres, or approximately 1,300 feet, will be secured. It is estimated that it will be possible to generate there at least 60,000 horse-power. According to present plans the plant will be ready for operation within four years. Besides sending current to Guadalajara and using it for irrigation purposes, Mr. Cuesta proposes to transmit current to Aguascalientes and other distant points. There is now demand for several thousand horse-power in Aguascalientes. A concession has been asked for the establishment of an electric plant to be operated by water power about 100 kilometres west of Durango. An English company is said to be back of the move. The object is to furnish light and power to the city of Durango. Mexico City capitalists have formed a company to install a telephone system in Guanajuato. The company has obtained the right to erect poles and already a number of local merchants and others have subscribed for the new service. Puebla is to have a second telephone system. Alejandro M. Azan is organizing a company, to be capitalized at $400,000, to install a new underground telephone system. Application has been made for a concession and, as the new company has the backing of the chamber of commerce, it is believed the concession will be granted within a few weeks. It is hoped to begin construction within two months. A metallic-circuit system will be installed with all wires under-ground. In addition to the system in the city of Puebla, the company will construct long-distance lines to Atlixco, Cholulu and Tlaxcala and establish local exchanges in those cities. The company will charge $5 a month for business telephones and $3 a month for residence telephones. It is expected the exchange will begin with 800 telephones in Puebla and 300 in the surrounding towns. The announcement is made by Mr. Azan that he has assurances that the Federal government will construct a long-distance telephone line from Puebla to the City of Mexico. This line, when completed, will be operated by the new telephone company, thirty per cent of the gross receipts being paid to the government for the use of the line.

ELECTRIC RAILWAYS.

EL PASO, TEX.—Citizens have subscribed $45,000 for building an interurban to Valley, thirty miles below this city.

FLINT, MICH.—Work on the extension of the Detroit, Flint & Saginaw electric railway from Frankenmuth to Flint will begin at once.

HOUSTON, TEX.—The Houston Electric Company intends to extend the Harrisburg line of the Houston Street Railroad down the bay shore to La Porte, Seabrook and other points.

NEWARK, N. J.—At an adjourned meeting of the West Orange town council a fifty-year franchise was given the Orange Mountain Traction Company to extend its line across Valley road.

ATTLEBORO, MASS.—The new electric car line connecting this town with Pawtucket and South Attleboro has been opened. This line is to be operated by the Interstate Consolidated Company.

FLORENCE, COL.—Engineers have been investigating the proposed line of electric railway from Turkey Creek through Florence to Cañon City. About seven miles of grading remain to be completed.

NORWAY, MICH.—A project is pending for the construction of an electric railway extending from Norway to the Spread Eagle Lakes, and passing through the village of Quinnesec and the city of Iron Mountain.

AKRON, OHIO—Application to incorporate the Turkeyfoot Traction Company, to connect Turkeyfoot Lake with Akron and Massillon, has been made by Tom L. Childs. The object is to touch the numerous lakes south of Akron.

LAWRENCE, KAN.—The city council has granted a franchise to the Kansas City & Kansas Southwestern Railway Company to construct an interurban line through Lawrence. The ordinance gives the company ninety days in which to accept the terms of the franchise.

HARRISBURG, ILL.—Promoters are contemplating connecting Eldorado, Harrisburg and Carrier Mills with an electric line. The project is backed, it is said, by the McKinley system, and W. A. Hass, of Lincoln, Ill., is having a preliminary survey of the route made.

JOHNSTOWN, PA.—A plan for the revival of the Johnstown, Ebensburg & Northern Railway project is being considered and likely to culminate shortly. This city and Gallitzin will be the terminal points and the proposed line will be thirty-two miles long and cost $1,200,000.

GOLDFIELD, NEV.—Plans are maturing for a trolley railway system for Goldfield. The directors will include George Wingfield, Denny Sullivan, T. F. Manning and Senator H. V. Moorehouse. The system will cost in the neighborhood of $125,000 and should be completed within a few months.

PHILADELPHIA, PA.—Judge Holland, of the United States Circuit Court, at Philadelphia, has issued a decree appointing John A. Riggs and George Blackenstone receivers of Philadelphia, Bristol & Trenton Street Railway Company. The plaintiffs are the Interstate Railway Company and the United Power and Transportation Company.

RED BLUFF, CAL.—The city trustees of Red Bluff have granted a franchise to the Northern Electric Company for the extension of its lines through the main street of the city. Connecting at Chico with the line now in operation, this extension will open up a rich section of the Sacramento Valley which has heretofore been only partially accessible.

MADISON, WIS.—The state railroad commission has granted the Milwaukee Light, Heat and Traction Company authority to extend its line from Waterford to Lake Geneva. There was no opposition to the request. This grant would indicate that President John I. Beggs is about to further extend the East Troy line and to further tap the Fox River Valley territory.

TACOMA, WASH.—The Tacoma Railway and Power Company has begun work on a new substation at Puyallup. The station will have an initial capacity of 500 horse-power. The building will be of brick, forty-five by fifty-five feet. The new station will furnish power for the operation of the short line through the valley and increase the efficiency of the present line.

SALT LAKE CITY, UTAH—At the session of the board of county commissioners an application for a franchise for the building of an electric line through Ogden Canyon was made by David Eccles and associates. The company asserts its desire to build the line through to the Oaks before winter sets in, and by next summer build on to Huntsville and other Ogden Valley towns.

HUNTSVILLE, ALA.—The transfer of the properties of the Huntsville Railway, Light and Power Company to the Huntsville, Chattanooga and Birmingham Interurban Railway, Light and Power Company has been effected. The new corporation has improvements in prospect, one of the first enterprises being an electric railroad to the top of Monte Sano. Electric power will be secured from the Tennessee River.

CARLISLE, PA.—Several local business men, headed by Willis E. Gladfelter, will apply shortly for a charter to build a trolley line running east along the Harrisburg, Carlisle and Chambersburg turnpike from Carlisle to Balfour, Middlesex township, Cumberland County, a distance of three miles. It is surmised that this road will connect with another running from Carlisle to Carlisle Springs, which is in projection.

UTICA, N. Y.—The stockholders of the Utica & Mohawk Valley Railway Company at their annual meeting elected the following directors: Horace E. Andrews, William K. Vandervilt, Jr., John Carstensen, Edward V. W. Rossiter, William C. Brown, Albert H. Harris, John J. Stanley, Walter N. Kernan, Charles B. Rogers, Nicholas E. Devereux and James S. Sherman. Shares to the number of 75,000 were voted.

MILWAUKEE, WIS.—The lines of the Chicago & Milwaukee Electric road are completed to and including connections in Milwaukee, and it is stated by Clement C. Smith, of the Columbia Construction Company, that cars can be operated on the system at any time. Work on the car barn and substation is well under way, as is the work of stringing wires between Milwaukee and Racine. The car barn is to cost $30,000. The site is 248 feet long and 121 feet wide.

DAYTON, OHIO—The Dayton Street Railway Company has increased its capital from $10,000 to $1,200,000. This company is constructing one of the longest city railway lines in Dayton, the route covering southeastern and northwestern Dayton, as well as traversing the central section of the city. Work of construction is being pushed at both ends, and the road will be ready for operation by the middle of November. It has been financed solely by Daytonians.

LOUISVILLE, KY.—A subcompany of the Evansville & Eastern has been incorporated to build an electric line from Rockport, Ind., east to New Albany, and across the Ohio River to Louisville, Ky. The capital stock is given at $10,000, but it is stated that an amendment will soon be filed increasing it to $1,000,000. The directors include: William H. McCurdy, of Evansville; John C. Haines, Marcus S. Sonntag, Albert F. Karges, William A. Kotch, C. H. Battin and William L. Sonntag.

CHICAGO, ILL.—The work of improvement on several sections of tracks of the Chicago Consolidated Traction Company lines has been authorized by Judge Grosscup before whom the receivership proceedings involving the company are pending. The order was entered in compliance with the petitions of the receivers, David R. Forgan and John M. Roach, who are given authority to use funds from the earnings of the lines or borrowed money. The expenditure will amount to $25,000.

KENDALLVILLE, IND.—Incorporation papers have been filed with the secretary of state by Attorney T. A. Redmond, representing a number of capitalists, for a new interurban line connecting Kendallville and Goshen through Ligonier with branches to Albion and Rome City. The capital is $10,000, which will be increased. A number of Kendallville capitalists are interested, among them being: H. I. Park, president of the Flint & Walling Manufacturing Company, and T. E. McCray, of McCray Refrigerator Company.

SEATTLE, WASH.—Stone & Webster, of Boston, have added to their extensive railway system in the state of Washington by purchasing the Seattle-Everett Interurban, a new electric line projected by Fred E. Sander and associates of Seattle, part of which has already been completed. The purchase price is not made public. It will be consolidated with the Seattle Electric Company, which operates the street electric car lines and the Puget Sound Electric Railway, the interurban line to Tacoma. The line will be extended from Everett to Bellingham, where it will form the north end of a proposed through electric line from Portland to the Canadian border in connection with the Puget Sound Electric road from Seattle.

NEW INCORPORATIONS.

COLUMBUS, OHIO—Lemoyne Telephone Company, Lemoyne. Capital increased to $10,000.

ALBANY, N. Y.—Heuvelton Heat, Light and Power Company. Heuvelton. $25,000. Incorporators: E. L. Thornton, E. F. Thornton, Chicago; A. Thornton, Heuvelton.

COLUMBUS, OHIO—Turkeyfoot Traction Company, Akron. $10,000. Incorporators: Thomas L. Childs, Charles J. Carey, Charles Esselburn, Frank E. Ream and D. W. Ruegsegger.

RICHMOND, VA.—Fredericksburg & Wilderness Telephone Company, Fredericksburg. $1,000 to $5,000. T. F. Morrison, president, Spotsylvania County; R. A. Jennings, vice-president, Orange, Va.; M. W. Thornburn, secretary and treasurer, Spotsylvania County. To operate a telephone line in the counties of Spotsylvania, Orange, Culpeper and Louisa.

SALT LAKE CITY, UTAH—The Monroe Light, Power and Milling Company, of Monroe, Sevier County. $25,000. Officers: John Manson, president; J. H. Erickson, vice-president; Jens N. Jeppson, secretary and treasurer. The concern takes over by purchase fifteen acres of land in Sevier County and other property consisting of an electric light plant and a grist mill.

PERSONAL MENTION.

MR. J. R. WILLIAMS, of Lisbon, Ohio, has assumed the management of the Bell Telephone Company's office at Meadville, Pa.

MR. PLAYER LITTLEFIELD has been appointed manager of the Knoxville office of the East Tennessee Telephone Company.

MR. F. M. HENKEL, assistant manager of the Bryan-Marsh Company, has left that company to open a branch office at 22 Fulton street, New York city, for the Tungstolier Company, of Cleveland.

MR. L. B. MARKS, consulting engineer, and MR. J. E. WOODWELL, recently engineer in the United States Government service, Washington, D. C., announce that they have opened offices in the Terminal Building, 41st street and Park avenue, New York city. Mr. Marks will continue his work in illuminating engineering and Mr. Woodwell will devote himself to power problems.

MR. E. J. KULAS, vice-president and general manager of the Tungstolier Company, of Cleveland, has just returned from a visit to the various Tungstolier branch offices at Boston, New York, Philadelphia, Pittsburg, St. Louis, Chicago, Kansas City, Minneapolis and Denver. On September 26 Mr. Kulas again left Cleveland, and on this trip will go to the Pacific Coast, where he proposes to establish branch offices in San Francisco, Los Angeles and Seattle.

MR. A. P. CRENSHAW, secretary-treasurer of the Chesapeake & Potomac Telephone Company, was the guest of honor at a dinner given in Washington, D. C., last Friday evening, in celebration of his thirty years of continuous service. Mr. Crenshaw was presented with a fine clock and was the recipient also of many personal appreciations from the officials of the company, about twenty-five of whom, from Washington, Baltimore, Philadelphia and New York, were present.

MR. H. H. CUDMORE has been engaged by the Brilliant Electric Company, of Cleveland, Ohio, as general sales manager. Mr. Cudmore has for the past twelve years been identified with electrical jobbing interests in and near Cleveland. As the product of the Brilliant Company is marketed very largely through jobbers, his knowledge and experience in the supply business will enable him to serve such customers to the best advantage. Mr. Cudmore assumed his new duties on September 1, since which date he has been on an extended trip through the East, making the acquaintance of his trade and studying business conditions.

OBITUARY NOTE.

LIEUTENANT THOMAS E. SELFRIDGE, who lost his life in the aeroplane accident at Fort Myer, Virginia, was buried with military honors at Arlington on September 25. Among the honorary pall-bearers were Major G. O. Squier, Lieutenant R. B. Creecy, Lieutenant G. C. Sweet, Dr. Alexander Graham Bell, Professor Octave Chanute, J. A. D. McCurdy, Percy Bradford, Professor Monroe Hopkins, F. W. Baldwin and W. J. Hammer.

NEW MANUFACTURING COMPANIES.

PHILADELPHIA, PA.—Harry V. Haden and Russell Klem, both of Philadelphia, are among the incorporators of the Turbine Equipment Company, of Trenton, N. J., mechanical, electrical, civil and contracting engineers, with a capital of $50,000.

SPRINGFIELD, ILL.—The International Telephone Manufacturing Company has been incorporated to manufacture telephone and telegraph devices with $60,000 capital. The incorporators are: F. M. Burmeister, H. Shafer and J. C. Burmeister, Chicago.

SPRINGFIELD, ILL.—The Arrow Electric Company, of Chicago, with a capital of $2,500, has been incorporated to manufacture and deal in electrical apparatus and appliances. The incorporators are: William M. R. Vose, Hubert E. Page and William C. McNitt.

ELECTRICAL SECURITIES.

The market is now in a fine state of seething excitement trying to follow the fluctuations of the political campaign. The slump of last week was followed by just as big a rally, and the opportunities to make or lose a dollar seem to be about even. Business, it appears, is beginning to show some improvement, entirely without consideration to campaign or stock market conditions. The long season of drought, which threatened ruin to farmers all over the country and imperiled vast forest reserves, appears to have been broken, and reports indicate that there have been heavy rains in every direction.

Dividends have been declared upon the following electrical securities: United Railways of St. Louis; regular quarterly dividend of 1¼ per cent on the preferred stock, payable October 10. Chicago Telephone Company; quarterly dividend of 2 per cent, payable December 31 to stock of record December 23. Previous dividends have been 2½ per cent quarterly. A circular sent to the stockholders also states that a stock dividend of 20 per cent on October 10 will be paid to holders of record October 3. Rochester Street Railway Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable October 1. Cincinnati & Suburban Bell Telephone Company; quarterly dividend of 2 per cent, payable October 1. Cincinnati Gas and Electric Company; regular quarterly dividend of 1⅛ per cent, payable October 1. Cincinnati Street Railway Company; regular quarterly dividend of 1½ per cent, payable October 1. New York & New Jersey Telephone Company; regular quarterly dividend of 1¾ per cent, payable October 15 to stock of record October 5. Electric Storage Battery Company; quarterly dividends of ¾ of 1 per cent on the common and preferred stocks, payable October 1. Wilkes-Barre Gas and Electric Company; regular quarterly dividend of 1 per cent, payable October 1. Bell Telephone Company of Missouri; regular quarterly dividend of 2 per cent, payable October 1. Central & South American Telegraph Company; regular quarterly dividend of 1½ per cent, payable October 1. Mexican Telegraph Company; quarterly dividend of 2½ per cent, payable October 16. Boston Suburban Electric Company; a dividend of $3 per share, payable in quarterly installments of seventy-five cents, beginning October 15. The first dividend is payable to stock of record October 5. The last previous dividend was at the rate of 3 per cent per annum and was paid October 15, 1907.

ELECTRICAL SECURITIES FOR THE WEEK ENDED SEPTEMBER 26.

ELECTRIC LIGHTING.

NEWARK, N. J.—Garfield is discussing the question of a municipal lighting plant.

HATFIELD, PA.—At a special election it was voted to establish an electric light system at a cost of $4,000.

REHOBOTH, DEL.—Rehoboth capital has organized an electric light company and is soliciting subscriptions.

DENVER, COL.—The Denver Gas and Electric Company is having plans prepared for a modern steel office building, six or seven stories in height.

SPRINGFIELD, MASS.—The Williamsburg selectmen have granted pole locations in the village to the Northampton Electric Lighting Company.

HAMILTON, OHIO—Contracts have been awarded by the board of public service for the extension of the lighting system to Lindenwald and East Hamilton.

IRON RIVER, WIS.—The Iron River water, light and power plant was destroyed by fire on September 17. The loss is about $10,000 covered by insurance.

McEWEN, TENN.—L. H. Hopkins has leased the electric light plant and will operate it. The plant heretofore has been running only half the night, but from now on it will be run all night.

CHESTER, PA.—The Spring Lawn water power and thirty-one acres of land near Lewisville, Chester County, have been sold to the Elk River Electric Light, Heat and Power Company for $3,000.

DELEVAN, WIS.—W. H. Tyrrell has been appointed receiver of the Delevan electric light plant in proceedings instituted by bondholders. The company was organized some ten years ago by local capitalists.

JOHNSTOWN, PA.—The city council has awarded a ten-year contract to the Citizens' Light, Heat and Power Company to furnish street arc lamps for $50 each per year, reserving the right to cancel the contract at the end of five years.

MITCHELL, S. D.—The Mitchell Power Company has awarded the contract for the construction of the new electric light plant to the Goetz Construction Company, of Yankton. Work on the building will be commenced as soon as possible.

ALBANY, N. Y.—The Public Service Commission, Second District, has authorized the Mexico Electric Company, of Mexico, Oswego County, to issue $10,000 in bonds to purchase from Edwin L. Huntington, of Mexico, the electric light plant there.

WAYCROSS, GA.—It is reported that George W. Deen, Burdett Loomis and Harley Pettibone will start work at once on an electric light plant for Waycross, and also build a street railway system, extensions of time having been granted on the franchises granted some time ago.

ALBANY, N. Y.—The Public Service Commission, Second District, has authorized the Cataract Power and Conduit Company, of Buffalo, to issue $125,000 five per cent bonds to be secured by a first mortgage dated January 1, 1907. The bonds shall not be sold at less than ninety per cent of par value.

GOSHEN, IND.—Injunction proceedings have been filed against the city of Goshen, Ind., to prevent the rebuilding of the municipal lighting plant at an expense of $45,000. The suit is based on the contention that the municipality is breaking the legal limit of its indebtedness; that the question was not submitted to taxpayers at special election.

MARLBORO, MASS.—According to a statement the Marlboro Electric Company has made a contract with the Connecticut River Power Company to furnish the Marlboro company additional power for use in operating its business in Marlboro, Southboro and Northboro. The power to be furnished by the Connecticut River Power Company will be transmitted to Marlboro from Clinton.

BATH, N. Y.—The Public Service Commission, Second District, has authorized the Citizens Electric Service Company, of Bath, to issue $75,000 bonds and to issue $50,000 common stock. None of the bonds shall be sold for less than eighty-five per cent of their par value. Ground for the company's plant has already been broken. At a meeting Charles I. Davison, village treasurer, was elected treasurer of the company, and S. J. Richard, of Buffalo, vice-president.

PHENIX CITY, ALA.—At a meeting of the Phenix City council an ordinance was read granting a franchise to the Phenix-Girard Power and Lighting Company, a new corporation which proposes to establish a steam plant for furnishing electric light and power. A franchise has already been granted in Girard. The leading spirits in the enterprise are T. W. Butts and B. A. Bass, of Columbus, and I. I. Moses and D. C. Foster, of Girard.

OMAHA, NEB.—An ordinance providing for the construction and purchase of a hydroelectric light and power plant to be owned, maintained and operated by the city of South Omaha, has been introduced in council. The ordinance involves the proposition of the Nebraska Power Company to build a plant for the city. The plant will be built at a cost of $2,500,000. The city will be permitted to pay for the plant in yearly installments out of the proceeds of the sale of light and power. The proposition has met with favor.

ST. LOUIS, MO.—It is announced that the Clayton Electric Company, composed of county capitalists, will push its application for a franchise for furnishing light in the county. The application was filed last spring, but no action was urged on the court. The action of the County Court in granting an extension of territory to electric concerns without any reservation as to the price to be charged has decided the local men, it is said. The Clayton company proposes to furnish current at a price greatly below the figures county consumers are now paying.

BERLIN, MASS.—The franchise granting the Marlboro Electric Light Company the privilege of extending its line from Marlboro to the Clinton line through Berlin, has been signed by the committee appointed by the town. By the terms of the franchise Berlin will have thirty-two electric street lights, to be distributed through the three villages and the intervening streets. They are to be incandescent lamps of forty candle-power. The cost annually will be $17.50 per light. The system is to be put in within six months.

WENATCHEE, WASH.—The Valley Power Company, of Wenatchee, reports that its new power plant will be ready for active operation by October 15. Twelve miles of the transmission line will be completed and the company expects to deliver power to Cashmere and other points along the line. Several pumping plants for irrigation will be installed and will be operated by power from this source. The company expects to extend its line down the Columbia River to Malaga and other points where power will be needed for pumping projects. The company will endeavor to secure a franchise to enter Wenatchee where it will compete with the Wenatchee Electric Company and the proposed Entiat Power Company, now asking for a franchise to enter that city.

DATES AHEAD.

Illuminating Engineering Society. Annual convention, Philadelphia, Pa., October 5-6.

Empire State Gas and Electric Association. Annual meeting, New York city, October 7.

Kansas Gas, Water, Electric Light and Street Railway Association. Annual meeting, Pittsburg, Kan., October 8-9.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J. October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

Railway Signal Association. Annual meeting, Washington, D. C., October 13-15.

Order of the Rejuvenated Sons of Jove. Annual meeting, Buffalo, N. Y., October 15-16.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October 20-23.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Association of Car-Lighting Engineers. First annual meeting, Chicago, Ill., November 18.

National Society for the Promotion of Industrial Education. Annual meeting, Atlanta, Ga., November 19-21.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

INDUSTRIAL ITEMS.

PASS & SEYMOUR, INC., Solvay, N. Y., has prepared a complete new price list and discount sheet, giving entire revised figures on its entire line. Copies may be had upon request.

THE AMERICAN CIRCULAR LOOM COMPANY, Chelsea, Mass., is distributing a folder combining with its advertising of "Circular Loom," "Electroduct" and "Lutz" metal molding, some data of campaign interest.

THE AUTOMATIC ELECTRIC COMPANY, Chicago, Ill., has published a handsome campaign souvenir in the form of a political atlas, giving a compendium of facts and figures, platforms, biographies and portraits of the men and the issues.

THE SIEMENS & HALSKE A.-G., Berlin-Nonnendamm, has published in English a very interesting catalogue and price list, No. 56, devoted to "Testing Instruments and Accessories." The company is represented in the United States by Dr. Karl Georg Frank, Hudson Terminal Building, 50 Church street, New York city.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., announces that a large contract was signed with the firm of Guinle & Cia., Brazilian agents for the General Electric Company, for the supply of electric energy to the Central Railway of Brazil, which is known as the largest enterprise of its kind in that country, for all purposes, which will include the supply of energy as motive power, as soon as the project now pending for the electrification of a section of that railroad is decided upon. To this firm was also granted a federal concession, covering the supply of light and power to the city of Sao Paulo, which aggregates 300,000 inhabitants, and is known as the largest coffee market in the world.

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, Pa., has issued the second section of a new series of sectional price lists. This covers the elements, jars and tanks of the "Chloride Accumulator" for electric railway, central lighting and power, isolated lighting, interlocking switch and signal, telephone, telegraph, fire alarm, laboratory, small motor work and miscellaneous service. This price list will be known as Section A and will be followed by other sections covering the many applications of the "Chloride," "Exide" and "Tudor" accumulators. Copies will be forwarded upon application to any of the sales offices of the company. Section C, covering the "Chloride Accumulator" and "Tudor Accumulator" for car-lighting service, was issued in June.

J. G. WHITE & COMPANY, engineers and contractors, 43-49 Exchange place, New York, has begun the surveys for F. H. Buhl, of Sharon, Pa., on one of the largest irrigation projects ever undertaken, contemplating the reclamation of about 700,000 acres of arid land in Southern Idaho. The project is practically an extension of the noted Twin Falls development. Water supply for the proposed extension will be obtained from Snake River. The lands lie to the west of the Twin Falls tract beyond Salmon River and in part beyond Bruneau River. The surveys in progress include reservoir sites, the enlargement of the present Twin Falls Canal, which was developed by Mr. Buhl, to a capacity sufficient to carry the increased water supply, an extension of the main canals to cover the lands of the project, including a syphon to carry the water supply across Salmon River Canyon, which is about 1,650 feet wide and whose bed is 500 feet below the level of the proposed canal. Five surveying parties are already in the field at work on the various parts of the project.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing its 1909 general catalogue, which is a handsome volume of 1,024 pages. Unquestionably, it has been the company's aim to make this catalogue the most complete electrical supply catalogue ever issued, and one needs only to look through the catalogue to be convinced of this. Considerable space is given to the specialties for which the company acts as sales agents, namely, Columbia incandescent lamps, Pittsburgh transformers, Okonite wires and cables, G-L arc lamps and New Lexington high-tension insulators. One is naturally interested also in the extensive line of fixtures which is shown and which naturally gives some conception of the fixture department, which is the most extensive in the West. The special announcement printed on the last page of the catalogue is also interesting as outlining in a general way some of the company's plans for expansion. The company is desirous of placing a copy of this catalogue in the hands of every individual who is actively engaged in plant operations, or who has anything to do with the specifying or purchasing of electrical material.

Record of Electrical Patents.

Week of September 22.

899,024. PARTY-LINE-INDICATING KEY. Clifford C. Bradbury, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed August 3, 1907. The actuating buttons have reciprocating and rotating means for indicating position.

899,068. APPARATUS FOR DETECTING INFLAMMABLE GASES IN AIR. Arnold Philip and Louis J. Steele, Portsmouth, England. Filed September 9, 1907. Means are provided for actuating a visual signal in connection with a catalytic agent.

899,088. GOVERNOR FOR DYNAMOS. Charles L. Weichelt, Philadelphia, Pa. Filed December 11, 1907. The armature is slidably carried on a shaft which is equipped on one end with a coned pulley.

899,127. MEANS FOR PROTECTING HIGH-TENSION OVERHEAD ELECTRIC CONDUCTORS. Lucian Neu, Lille, France. Filed April 3, 1906. Inductive resistances are included in the circuit to shunt certain sections of the circuit.

899,134. ELECTRIC SIGNALING SYSTEM FOR RAILWAYS. Ara P. Rickmire, Waterloo, Iowa. Filed December 30, 1907. Current is supplied through relays and switch points, one rail forming a continuous circuit; and sectional rails are connected to a source of power through the relays.

899,145. ELECTRICAL SYSTEM OF DISTRIBUTION. William A. Turbayne, Lancaster, N. Y., assignor to Gould Storage Battery Company. Filed February 25, 1907. A multi-voltage booster system.

899,153. BLOCK-SIGNAL APPARATUS. Alexander Bevan, Providence, R. I. Filed December 3, 1906. An oscillatory shaft equipped with a target is actuated by an electromagnet.

899,189. ELECTROMOTOR CONTROLLING AND OPERATING SYSTEM FOR ELECTRIC RAILWAYS AND POWER PLANTS. Johann Sahulka, Vienna, Austria-Hungary. Filed June 1, 1907. A two-motor series-control operating system.

899,193. AUTOMATIC ELECTRICAL MEASURING APPARATUS. Daniel J. Shine, Las Vegas, Nev. Filed March 4, 1907. Resistances of relatively large and small quantities are alternately switched into circuit.

899,205. ELECTRIC SWITCH. Charles A. Clark, Hartford, Ct. Filed May 24, 1907. A quick-break snap switch.

899,209. AUTOMATIC TELEGRAPHY. Patrick B. Delany, South Orange, N. J., assignor, by mesne assignments, to the Telepost Company of Maine. Filed December 15, 1896. Means are provided for transmitting signals corresponding to perforations on a tape.

899,220. AUTOMATIC ELECTRIC SAFETY DEVICE FOR BOILERS, ETC. Charles Kausen, New York, N. Y. Filed March 13, 1908. The movement of a plunger actuates a circuit-closing mechanism.

899,226. ELECTROPLATING APPARATUS. George A. Lutz, Plainfield, N. J., assignor to American Circular Loom Company, Portland, Me. Filed June 6, 1908. Means are provided for supporting articles to be plated within a hollow insulating cylinder.

899,234. MASSAGING INSTRUMENT. Julius B. Wantz, Chicago, Ill., assignor to Victor Electric Company, Chicago, Ill. Filed October 23, 1907. A massaging member is actuated by the motor through a universal joint.

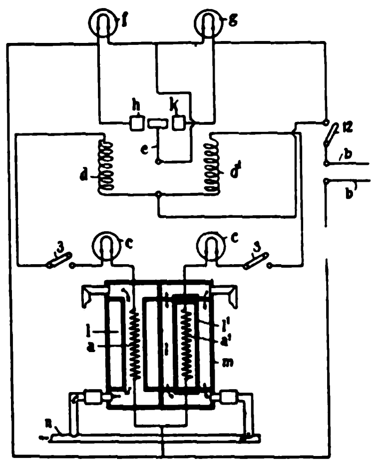
899,239. SIGNALING SYSTEM. Sewall Cabot, Brookline, Mass., assignor to Stone Telegraph and Telephone Company, Boston, Mass. Filed March 10, 1906. A combination of a wireless telegraph system and a wire telegraph system.

899,240. SIGNALING SYSTEM. Sewall Cabot, Brookline, Mass., assignor to Stone Telegraph and Telephone Company, Boston, Mass. Filed March 10, 1906. A combination of a wireless telegraph system and an open-circuit wire telegraph system.

899,241. SIGNALING SYSTEM. Sewall Cabot, Brookline, Mass., assignor to Stone Telegraph and Telephone Company, Boston, Mass. Filed March 10, 1906. An intermediary wire telegraph system is provided with relays adapted to transmit wireless telegraph signals.

899,242. SIGNALING SYSTEM. Sewall Cabot, Brookline, Mass., assignor to Stone Telegraph and Telephone Company, Boston, Mass. Filed March 10, 1906. A combination of a multiplex wireless telegraph system and a multiplex wire telegraph system.

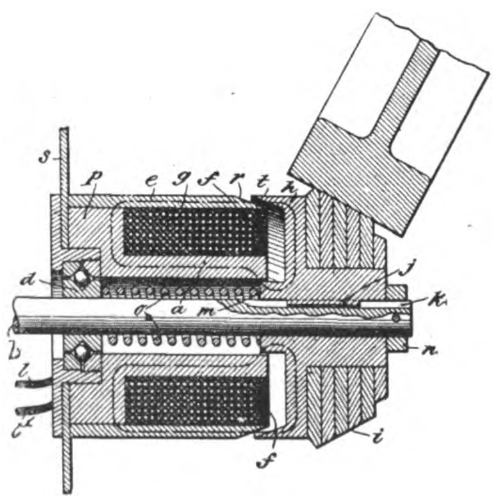
899,243. SPACE TELEGRAPHY. Sewall Cabot, Brookline, Mass., assignor to Stone Telegraph and Telephone Company, Boston, Mass. Filed April 4, 1906. An electromagnetic oscillatory detector.



899,068.—Apparatus for Detecting Inflammable Gases in Air.

899,264. OSCILLATION DETECTOR. Charles E. Russell, Cambridge, Mass., assignor to Stone Telegraph and Telephone Company, Boston, Mass. Filed September 4, 1906. The permeability of the magnetic circuit is varied by the electrical oscillations.

899,272. APPARATUS FOR DETERMINING THE DIRECTION OF SPACE-TELEGRAPH SIGNALS. John S. Stone, Cambridge, Mass., assignor to William W. Swan, trustee, Brookline, Mass. Filed August 17, 1906. The position of the ungrounded elevated conductors is capable of being changed relatively to the direction of motion of the electromagnetic waves.



899,088.—Governor for Dynamos.

899,278. TELEPHONE SWITCHBOARD. Charles E. Wilson, Philadelphia, Pa., assignor to Keystone Telephone Company of Philadelphia, Pa. Filed September 10, 1904. A multiple-position, manually operated switchboard.

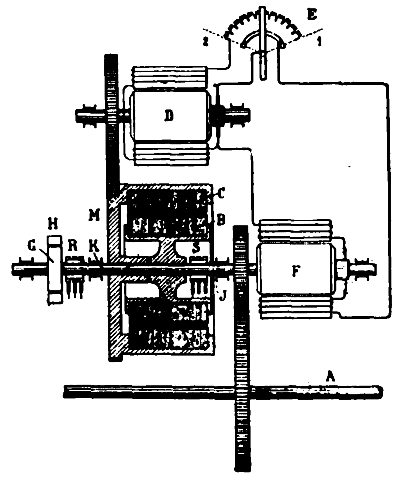
899,307. TELEGRAPH SOUNDER. Lee Kiblinger, Jackson, La. Filed November 18, 1907. Means are provided for equalizing the density of the magnetic field between the armature and different parts of the pole-pieces.

899,348. MAGNETIC ORE-SEPARATOR. Charles E. Stebbins, Iola, Kan. Filed April 17, 1908. A plurality of electromagnets are mounted upon a rotatable spider, a commutator and brushes being provided for supplying current to the magnets.

899,353. ALTERNATING-CURRENT BLOCK-SIGNALING SYSTEM. Jacob B. Struble, Swissvale, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed April 1, 1908. Relays are controlled by sectional track circuits controlling the home signals.

899,358. ARRANGEMENT OF PROTECTIVE APPARATUS. Hermon L. Van Valkenburg, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed September 29, 1906. The actuating members of a multiple switch are enclosed in fireproof chambers.

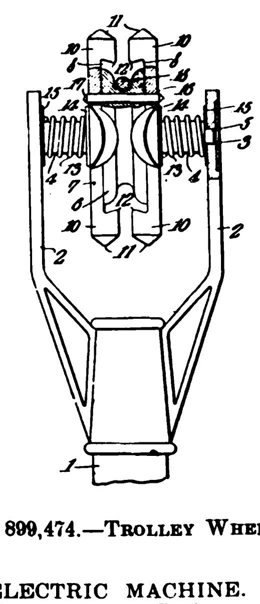
899,364. ELECTRIC SEPARATOR. Henry A. Wentworth, Lynn, Mass., assignor to Huff Electrostatic Separator Company, Boston, Mass. Filed February 3, 1908. The conductive material forms a barrier between the electrodes and is supplied to a rotating cylinder from a hopper.



899,189.—Electromotor Controlling and Operating System for Electric Railways and Power Plants.

899,370. DYNAMOELECTRIC MACHINE OF THE ENCLOSED TYPE. Alfred H. Wouters, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed March 18, 1907. The machine is enclosed in a housing having an air-receiving and an air-admission chamber.

899,379. PARTY-LINE-INDICATING KEY. Clifford C. Bradbury, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed March 11, 1907. The position of the key indicates the last set of switch springs actuated and released.



899,474.—Trolley Wheel.

899,447. DYNAMOELECTRIC MACHINE. Allan B. Field, Norwood, Ohio, assignor to Allis-Chalmers Company and the Bullock Electric Manufacturing Company. Filed November 30, 1906. A low-resistance ring, independent of the lamina and end plates, is embedded in the pole-piece at right angles to the lamina.

899,474. TROLLEY WHEEL. Joseph W. Seibert, Washington, Pa., assignor of one-half to Elias Lewis, Washington, Pa. Filed February 5, 1908. The trolley wheel is held in position by guide members, and is equipped with openings to lock the parts for a rotary movement.

CONTENTS

CONVENTIONS AND MEETINGS.

Every once in a while it seems as though certain psychological forces had impelled those in charge of arrangements for the meetings of the various engineering societies to group their dates as near together as possible. Technical journals, both here and abroad, have often called attention to the activities of the various engineering organizations coming too closely together, and once again we are in the midst of a plethora of conventions and meetings.

From all over the country trooped the Old Time Telegraphers and the members of the Society of the United States Military Telegraph Corps to attend their annual convention at Niagara Falls. Then, down in Chattanooga, Tenn., the American Institute of Mining Engineers held forth the first few days of the month. Philadelphia, with its two hundred and twenty-fifth anniversary and celebration of Old Home Week, was the meeting place of the Illuminating Engineering Society in annual convention for two days on October 5 and 6. The Empire State Gas and Electric Association held its annual meeting in New York city on October 7, and on October 9 our own American Institute of Electrical Engineers held its first fall meeting. The New York Electrical Society opens its season with a meeting on Monday night at the New York Electrical Show, the latter running from October 3 until next Wednesday evening. Flying to the West, the Kansas Gas, Water, Electric Light and Street Railway Association held its annual meeting at Pittsburg, Kan., on October 8 and 9, and, coming again to the East, the whole week of October 12 to 16 is devoted to the conventions of the American Street and Interurban Railway Association and its affiliated organizations. The Railway Signal Association holds its annual meeting at Washington, D. C., October 13, 14 and 15, and the Order of the Rejuvenated Sons of Jove turns Buffalo upside down on October 15 and 16. The American Society of Municipal Improvements holds its annual meeting at Atlantic City, October 20 to 23, and the American Electrochemical Society closes this convention month with its fall meeting in New York city on October 30 and 31.

There are enough engineers and others interested in each particular line to make every one of these meetings a success, but there are a large number of engineers—and these happen to be very prominently connected with the electrical industry—who are interested in more than one branch of the service, and the close proximity of the dates makes it impossible to attend the meetings they would wish to even in these days of easily audited expense accounts and space-annihilating express-train service. The programmes, too, which have been and will be discussed at these meetings are of particular interest at this time. The Papers Committee of the American Institute of Electrical Engineers very wisely announces that for the coming season there will be but one paper presented at each meeting, this to be accompanied by written discussion which must be prepared in advance, and the formal reading of which will be disposed of by ten o'clock, leaving whatever time may be desired for open discussion after that hour. It is expected that because of this decision, engineers will be able to devote more time to the preparation of their papers, and that the papers will be received considerably in advance of their date of delivery. A fuller discussion will be secured, and those who attend the meetings and contribute most brilliantly to their value and importance by extemporaneous suggestions will not be handicapped and embarrassed because of lack of time and the apparent weariness of those listening.

The plans of the American Street and Interurban Railway Association and its affiliated societies, as usual, are being completed in good season, and it is expected that the conventions which will be held next week at Atlantic City will be the most successful which these progressive organizations have ever undertaken. The entire expanse of the million-dollar pier will be covered with exhibits of every character of device which appertains to street and interurban railway service.

THE REPORT OF THE PUBLIC SERVICE COMMISSION FOR THE FIRST DISTRICT OF THE STATE OF NEW YORK.

The report of the Public Service Commission for the First District of the State of New York, covering the six months from July 1 to December 31, 1907, gives us the first coherent and tangible evidence of what this important body has accomplished and of its aspirations for the future. Although we are familiar with the wealth and extent of the metropolis over which this commission holds certain sway, we can not help feeling more than impressed when a perusal is made of some of the figures presented in this report.

The commission for the first district has jurisdiction over the counties of New York, Kings, Queens and Richmond, making up the greater city of New York. The Public Service Commission for the Second District has jurisdiction over the remainder of the state. Each commission consists of five men appointed by the governor by and with the consent of the Senate. After February 1, 1909, each appointee will serve for a period of five years. The Public Service Commissions succeeded to the powers of the Railroad Commissioners, the Commission of Gas and Electricity, and the State Inspector of Gas Meters. The Board of Rapid Transit Railroad Commissioners, of New York city, was also abolished by the act. The commission for the first district thus has dual powers: on the one hand having full and complete powers of regulation over all public service corporations, and, upon the other, having the task of planning and constructing, and possibly also of equipping and operating, rapid transit lines, whether subway or elevated.

Within the first district there are sixteen gas companies, nine electric companies and three companies furnishing both gas and electricity, with 1,011,831 gas consumers and 87,745 consumers of electricity. The total capitalization of these companies on June 30, 1907, was $353,299,533.80. Their gross earnings from operations for the year were $48,363,840.29. Their expenditures for operation were $36,318,494.09. They paid, either as interest on bonds or dividends on stock, $12,370,091.57. The amount of gas manufactured reached the total of 34,656,922,800 cubic feet. The electricity produced amounted to 424,027,824 kilowatt-hours.

The cost of road and equipment of the street surface, elevated and subway railroads under the jurisdiction of the commission for the year ended June 30 was $459,802,017.89. The permanent investment, cash and other assets amounted to $164,274,208.26. The total earnings from passenger operation were $65,568,031.89.

The total number of passengers carried by all the railroads of the state was 1,630,775,156, of which 105,757,957 were carried by steam roads, and the balance by street surface, elevated and underground railroads. Of the latter, 1,249,829,568 were carried by the railroads now operating under the jurisdiction of the commission for the first district.

The commission held 179 hearings between July 18 and December 31, as a result of which 186 orders have been issued. One of the important matters to which the commission gave considerable attention concerned delays in transportation and inadequate facilities for comfortably moving the passenger traffic. A conservative estimate of the increases required of all the operating companies indicates that over 15,000,000 additional seats per annum have been added to the service in New York city under the orders of the commission.

MAGNETIC STORMS AND SUN SPOTS.

One of the departments of astro-physical science which is engaging the attention of the keenest intellects of the day is that branch which undertakes research into the phenomena which we have designated as terrestrial magnetism. It seems peculiar that the studies of one group of scientists and physicists along the lines of terrestrial magnetism have reached so many points of co-ordination with the discoveries made and announced by another group of physicists which has devoted itself to research into the phenomena of the ultimate constitution of matter and the newer theories of electricity and life.

Persuaded of the correctness of Lorentz's theory of the electromagnetic nature of light, Dr. P. Zeeman made repeated experiments to discover proofs substantiating his belief. In 1897 he was able to demonstrate that the magnetic field exerts a remarkable effect upon monochromatic light. Dr. Zeeman placed a flame from a Bunsen burner between the poles of a powerful electromagnet, and placed in the flame a bit of asbestos impregnated with a salt solution of sodium. When the flame, with the burning sodium vapor, was observed through the slit in a spectroscope, Zeeman discovered that what was ordinarily a single line appeared, when under the influence of the magnet, to be a broadened or double spectral line. Various theories were advanced to account for this, but repeated experiment convinced him that he had demonstrated an entirely new effect, and the scientific world, in acknowledging to the doctor its appreciation, designated the phenomenon as the Zeeman effect.

Last June Professor George E. Hale, formerly the director of the Yerkes Observatory, and now conducting special researches on Mount Wilson, in California, made a number of exceptionally clear photographs of the spectrum of a certain disturbed area of the sun's surface. An examination of these photographs showed that one of the lines which is usually single appeared double. Professor Hale has the reputation of being a very careful observer and a close student of astro-physical phenomena. He did not make any announcement himself, but forwarded several of the photographs, together with a statement of his deductions, to Dr. Zeeman. Dr. Zeeman's acknowledgment of this communication and his opinion concerning the importance of Professor Hale's discovery appeared in the issue of *Nature* for August 20, last. Dr. Zeeman expresses the opinion that the division of the line in question shows that the region photographed was a magnetic field. Some other explanation may later be offered for this phenomenon, but the coincidence is remarkable, and until some better authority is given, we must, perforce, be satisfied with the deductions made by Dr. Zeeman and Professor Hale.

It appears that we are rapidly tending toward some very important discoveries in the realm of terrestrial magnetism and the electromagnetic theory of light. That there is a close connection between solar disturbances and terrestrial magnetism has been the opinion of several of the greatest intellects of modern times, and possibly Professor Hale's discovery will prove another link in the chain which is binding the study of these forces together. It is true that there appears to be some material coincidence between solar disturbances, usually manifested as sun spots, and unbalancing of telegraph systems, distortion of terrestrial magnetic forces, eruptions, spasmodic and unseasonable storms and unexpected occurrences of the aurora borealis. These coincidences have not been sufficiently marked to be considered of fundamental value to the forecasters of the Weather Bureau, but much work is being done by government and private observers, tabulating such data as will possibly make future forecasting considerably more definite than it is to-day. Certainly, there seems to be material of great value in the discovery of Professor Hale and in the opinion of Dr. Zeeman. Apparently the same influence which causes the sodium line in the spectrograph of the Bunsen flame to be affected and split up affects the observed line in the spectrograph of the solar disturbance. This would seem to indicate that either there is a powerful external magnetic force acting on the sun at the time of the disturbance, or that the sun is exerting a powerful magnetic force upon some exterior object at the time. An exact knowledge of this phenomenon will help us in weaving together many of the to-day little-understood manifestations of nature, and it is to be hoped that from this new start considerable progress will soon be made.

ACCIDENT ON THE LONDON SUBWAY SYSTEM.

A special cable despatch from London, October 3, states that a breakdown of turbines in the Chelsea station caused the interruption of traffic in the entire London subway system on the afternoon of that day. As this occurred during the rush hours of the Saturday half-holiday, when everybody is trying to get home, and as it was of exceptionally long duration, it caused much distress to the traveling public.

As was but natural many of the trains stopped between stations, the despatch states, and the passengers left the trains, and by the guidance of the train crews with lanterns, reached the nearest stations. Although the congestion in the tunnels and stations was great, no one was hurt. Traffic was again resumed in the evening.

Whatever the trouble was, whether on the mechanical or electrical end, it seems strange that the cause was not located and remedied in a shorter time. In our own Metropolitan traction system, once in a while, interrupted by trouble at the generating station, the delay in traffic usually does not exceed twenty minutes.

It will be remembered that the Chelsea plant is the largest generating station in Great Britain. It contains eight 5,500-kilowatt and two 2,700-kilowatt turbo-generator sets, which feed a single main bus-bar system cut up into five sections by sectionalizing switches.

As has been advocated time and again in the pages of the Electrical Review, the wiring diagram of any station, particularly those for electric traction, can not be too flexible. Usually the feasibility of expending a few dollars for extra apparatus for emergency cases does not become apparent until large sums are lost due to interrupted operation. The foresight, in addition to these precautions, has led large railroad corporations to provide emergency connections with other generating stations so that, in case of a severe accident to one station, the various substations along the line receive current from another source.

Such interconnections between stations not only cut down the duration of delays, but also, to a certain extent, reduce the number of reserve units usually held in a single generating station. Frequently, when the trouble is on the electrical end of the plant, the reserve units can not be thrown on the line until the trouble is located and remedied. When possessing the availability of another source of power the question is a different and an easier one. When emergency power is required from such a station it takes but a few minutes to have the reserve units started, synchronized and thrown on the line. Of course the different generating stations must have separate feeders to the various substations, which is of consequent importance, as otherwise there is the possibility of attempting to send current into a not located disabled section.

Not all railway systems can rely upon power sources of another plant, if such is the case, and continuity of operation is desired, the generating plant must be provided with a double bus-bar system with several sectionalizing switches, and double feeder systems to the various substations. The feeder sections from the substations must also be run in duplicate.

The New York Electrical Show.

THE second annual electrical show held at Madison Square Garden, New York city, was opened on Saturday evening, October 3, at 8 o'clock. This show commemorates the fifty years of transatlantic communication by cable, and the passage of the first quarter century of electrical service in New York. On the opening night the visitors beheld a worthy successor to the very successful show which was held in New York city a year ago. The scheme of decoration was in entire harmony with the brilliant illumination, and the preponderance of metallic-filament lamps, together with the uniform color scheme, created an ensemble of cheerfulness which has seldom been approached in decorative lighting.

The opening exercises, which were held in the concert hall, at 8.30 P. M., were rendered entirely by means of Edison phonographs, the records being taken by the Edison Business Phonograph Company, of Orange, N. J. This is the first time that the entire exercises of a meeting of this character have been conducted by a talking machine. The records were made in different parts of the country, and the programme included an introduction by Thomas A. Edison, president of the New York Electrical Show. Mr. Edison's remarks were as follows:

"Those of us who began our labors at the operator's key fifty years ago have been permitted to see and assist in the whole modern industrial development of electricity. Since the remarkable experiments of Morse in 1844 and the unsuccessful efforts of Field in 1858, there have come with incredible rapidity one electrical art after another, so that in practically every respect civilization has been revolutionized. It is still too early to stand outside these events and pronounce final judgment on their lasting value, but we may surely entertain the belief that the last half of the nineteenth century was as distinct in its electrical inventions and results as the first was in relation to steam.

"The lesson of the jubilee of the Atlantic cable of 1858 is one of encouragement to all who would add to the resources of our race and extend our control over the forces of nature. Never was failure more complete, never was higher courage shown, never was triumph more brilliant than that which since 1866 has kept the old world moored alongside the new by pulsating cables of steel and copper—the "family ties" of the civilized world.

"When I look around at the resources of the electrical field to-day as shown in this exhibition, I feel that I would be glad to begin again my work as an electrician and inventor; and we veterans can only urge upon our successors, the younger followers of Franklin and of Kelvin, to realize the measure of their opportunities and to rise to the height of their responsibilities in this day of electricity."

Mr. Edison's introductory remarks were followed by two-minute addresses by Louis A. Ferguson, Chicago, Ill., president of the American Institute of Electrical Engineers; W. C. L. Eglin, Philadelphia, Pa., president of the National Electric Light Association; W. W. Freeman, Brooklyn, N. Y., president of the Association of Edison Illuminating Companies; E. G. Acheson, Niagara Falls, N. Y., president of the American Electrochemical Society; H. A. Lardner, New York, N. Y., president of the New York Electrical Society.

The show was declared open in a brief phonographic speech by the Hon. Charles E. Hughes, governor of New York.

Following the formal opening exercises, the proceedings in the concert hall were continued by the esperanto societies of New York and vicinity.

Among the more prominent exhibits were those of the New York Edison Company, the United Electric Light and Power Company, the Brooklyn Edison Company, the General Electric Company and the National Electric Lamp Association.

The exhibit of the Campbell Electric Company, of Lynn, Mass., consisted of bell-ringing transformers and other specialties.

The Driver-Harris Wire Company, Harrison, N. J., exhibited resistance wires and wire specialties.

The Eastern Sales Company, New York city, exhibited its instantaneous water heater.

The Edison Electric Illuminating Company of Brooklyn made a very remarkable display. The exhibit was divided into three sections, showing industrial, commercial and domestic applications of electricity. Easily understood practical working exhibits were in operation, and the visitors were afforded a clear demonstration of the advantages of using the electric service. The self-supporting tungsten campaign which the Brooklyn Edison Company has been conducting was graphically described, and the centrepiece of the mural decoration overtopping the Brooklyn exhibit, which extended clear across the Fourth avenue end of the Garden, called attention to the rapid growth of electric service in Brooklyn. The figures for the past decade were given and a promise made of a very great extension in the future.

The Edward E. Cary Company, New York city, made a display of stereopticon apparatus, using the "Fabius Henrion" noiseless carbons working on alternating current, and the Hallberg electric economizer.

The Electric Home Supply Company, New York city, had a live exhibit of electrical appliances for home use, including heating and cooking devices, Shelton vibrators and other small electrical devices.

The exhibit of the Electric Motor and Equipment Company, of Newark, N. J., was the centre of a great deal of attention, a flashing unit electric sign being shown in operation.

The Electrical Testing Laboratories, New York city, made an elaborate exhibit of stationary and portable photometers, and had in operation a 100,000-volt transformer making a spray test for insulation. Another unique demonstration at this booth was the projection on a transparent screen of the arc from a carbon arc, a magnetite arc and a flaming arc.

The Enos Company, New York city, exhibited a number of very handsome lighting specialties.

The Excello Arc Lamp Company, New York city, made a fine display of its flaming arcs and illuminated the entrance to the Garden with ten Excello lamps.

The F. Alexander Electric Company, New York city, displayed its miniature arc lamp, which is claimed to give a quality of illumination closely approximating daylight.

The Federal Sign System, New York city, exhibited its unit letter and panel signs.

The Fox Brothers Company, New York city, exhibited the "Polar," the "Radiante" and the "Radiante Economy" flaming arc and incandescent lamps.

The General Electric Company, Schenectady, N. Y., had a very handsome and complete exhibit of motor applications, and made a comprehensive demonstration of all forms of incandescent lighting for residence and industrial service. A feature which attracted much attention was a machine that applied a two-color sleeving to a pair of twisted telephone cords.

The German-American Electric Company, New York city, exhibited the Grant flaming arc lamps for alternating and direct currents.

The Goulds Manufacturing Company, New York city, exhibited electrically driven pumps.

The Habirshaw Wire Company, Yonkers, N. Y., had a very attractive reception headquarters and made an exhibit of wires and cables for various purposes.

The International Text Book Company, Scranton, Pa., made a very interesting historical exhibit and demonstration of its correspondence courses.

The Manhattan Electrical Supply Company New York city, exhibited a very comprehensive line of electrical specialties.

The Metropolitan Engineering Company, Brooklyn, N. Y., made an exhibit of its panel signs and attraction letters.

The Murphy Rectifier Company, Rochester, N. Y., exhibited a unique mechanical rectifying system.

The engineering department of the National Electric Lamp Association, Cleveland, Ohio, made its usual handsome display. Tungsten multiple lamps from one and one-quarter to thirty, and from 100 to 125 volts, were shown. The tungsten miniature low-voltage regular and meridian types of lamps were on exhibition operating in multiple at 1.25 watts per candle. A sign board was equipped with tungsten miniature lamps, and a showcase contained low-voltage lamps, operating on one and one-quarter to thirty-volt circuits. The arches of the booth and a ball surmounting the whole canopy were outlined with ten-volt frosted sign lamps. This lamp is being largely used for outlining, sign, decorative and show-case lighting. For the first time the twenty-five-watt, 100 to 125-volt tungsten lamp was shown, and was greatly admired for its adaptability to general residence illumination. The tungsten regular forty, sixty and 100-watt lamps were shown on the side arches, equipped with Holophane extensive, intensive and focusing types of reflector. The centre of the booth was illuminated with a tungsten 250-watt lamp equipped with a bowl reflector. The frosted-bulb tungsten meridian lamps in forty and sixty-watt sizes were used as pendants from the centre roof arches. On the side brackets there were mounted different kinds of Gem, tantalum and tungsten lamps, making a very pretty comparison. An attractive setting was given the tantalum forty and eighty-watt regular and meridian styles burning at two watts per candle. The engineering department of the National Electric Lamp Association is maintained by the following companies: The Banner Electric Company, the Brilliant Electric Company, Bryan-Marsh Company, the Buckeye Electric Company, Cleveland Miniature Lamp Company, the Colonial Electric Company, the Columbia Incandescent Lamp Company, Economical Electric Company, the Fostoria Incandescent Lamp Company, the General Incandescent Lamp Company, Munder Electric Company, New York & Ohio Company, the Shelby Electric Company, the Standard Electrical Manufacturing Company, the Sterling Electrical Manufacturing Company, the Sunbeam Incandescent Lamp Company, the Sunbeam Incandescent Lamp Company of Canada, Limited, the Warren Electric and Specialty Company.

The National Vacuum Company, New York city, exhibited its portable motor-driven cleaning machines.

The Numaticon Company, New York city, exhibited its sanitary method of cleaning for residence and industrial purposes.

The Otis Elevator Company, Yonkers, N. Y., made a very impressive exhibit of alternating-current and direct-current elevators for both push-button control and industrial service.

The Simplex Electric Heating Company, under the direction of Roger Williams, of New York city, made a fine display of electric heating and cooking appliances.

The Spencer Turbine Cleaner Company, New York city, exhibited its system of cleaning floors, walls, draperies, etc., by means of its compressed-air and exhaust system.

Stanley & Patterson, New York city, exhibited a very complete line of electrical devices and afforded a timely demonstration of the new Patterson wireless battery holder.

The Tel-Electric Music Company, New York city, equipped a suite of rooms with its electrical piano players.

The exhibit of the New York Edison Company was one of the most decorative features of the show. Elaborate reception headquarters were established, and a host of representatives was on hand to afford information to those seeking knowledge of the utility and desirability of electric service.

The Simes Company, New York city, exhibited a very complete line of fixtures for tungsten lamps.

The United Electric Light and Power Company, New York city, made a very comprehensive display of alternating-current apparatus. This included everything from heavy-duty elevator motors and industrial presses to incubators and brooders. In the company's historical exhibit there were shown a number of very amusing toys which acted peculiarly under the action of the alternating current. There was also in one corner of the booth an induction motor running submerged in water. The alternating-current lighting display was particularly effective, and afforded a very successful demonstration of the adaptability of the metallic-filament lamps to this service.

The Watson-Stillman Company, New York city, exhibited a fine line of motor-driven tools.

The Empire City Subway Company, New York city, made a fine exhibit of poles, cables, manholes and cable runs, and a complete welding and track-laying equipment mounted on a steel-truss truck.

The New York *Times* tendered the use of its searchlight during the show, and also maintained a wireless telegraph service in connection with the Marconi Wireless Telegraph Company. A motor-driven Mergenthaler linotype was used to compose messages as received, and these were taken hot from the machine and placed on a motor-driven printing press and distributed to those in attendance.

The Moore tube light, manufactured by the Moore Electrical Company, of Newark, N. J., illuminating the lobby of the Garden.

One of the features of the show was the historical exhibit and the prize essay competition which was conducted by the Educational Committee and the General Advisory Board in connection with the exhibition.

The show is scheduled to run until Wednesday, October 14.

Electrical Supplies for the Navy Department.

The Bureau of Supplies and Accounts will open bids in Washington, D. C., on October 13 for the following electrical material: Miscellaneous cable, 11,700 feet of telephone cable, miscellaneous electrical supplies, for delivery at Norfolk, Va.; miscellaneous conductor, 8,000 feet of silk and cotton lamp cord, miscellaneous electrical supplies, and 500 porcelain tubes, for delivery at Annapolis, Md.

THE ARKANSAS ASSOCIATION OF PUBLIC UTILITIES OPERATORS.

FIRST ANNUAL CONVENTION, HELD AT LITTLE ROCK, ARK., SEPTEMBER 17 AND 18.

The first annual convention of the Arkansas Association of Public Utilities Operators was held at Little Rock, Ark., September 17 and 18. The association was welcomed to the city by Mayor William R. Duley. President D. A. Hegarty, in his opening address, called attention to the necessity of appointing a committee which could confer with the state legislative committees upon questions affecting the public utilities corporations. Mr. Hegarty also made suggestions concerning meetings of the executive committee, and, in the name of the association, thanked the associate members for their activity and the support which they had given to the work of organization.

A paper was presented by B. C. Fowles, entitled "Source of Supply of Water for Municipalities." This paper described the conditions of water supply in the state of Arkansas, and the author gave a great many practical suggestions with regard to the utilization of driven wells.

A paper entitled "Roadbed Construction and Pavement" was presented by Edwin Hardin. An abstract of this paper follows:

During the past decade the necessity for permanent-track construction for paved thoroughfares has reached the street-car companies of the South and West even in the cities of comparatively small population. Not many years since want of practical experience, with a considerable variety in both material and method to choose from, caused great diversity in roadbeds. In this way every possible manner of construction and character of material has been thoroughly tested.

However, the application of the knowledge gained by actual experience is greatly hindered in many instances by city ordinances, specifying classes of rails, roadbed and tie methods that have proved unsatisfactory. It is the want of accurate knowledge and the want of confidence in the sincerity of street-car companies on the part of the city law-makers that delay the use of methods that have proved themselves superior to all others.

This article will be confined to a brief sketch of the factors that go into building a permanent track suitable for all conditions and which has been generally accepted as the most economical in the long run.

The subgrade should have at least ten inches of ballast, with a bottom course of No. 4 crushed rock, fully six inches in depth, topped to the level for the reception of ties with finer crushed rock, and should be well tamped. The coarse rock at the bottom will assist in drainage, which is very important, and every advantage should be taken of all opportunities to run tile from the subgrade into the city drainage. On account of the necessity for drainage, no concrete should enter into the composition of the subgrade.

Tie construction is always feasible and always reliable, and the tendency is to return to ties after a trial of stringer construction—wherever ordinances do not prevent. The treated tie may now be accepted as the most satisfactory for the permanent bed, especially where paving is used. Not only are treated ties thoroughly satisfactory, but also they are the cheapest in the long run. This is particularly true where tie-plates are used, and their use always is advisable. With ties placed twenty-one inches between centres there is no necessity for tie-rods, except where especially high rails are required.

Only the standard T-rail may be considered as satisfactory for general use. This section presents the best form of rail yet devised. It has the most economical disposition of weight, is thoroughly adaptable to all conditions of traffic and rolling-stock construction, and at the same time does not require expensive factory-made curves.

The use of girder and grooved rails is now almost limited to meet requirements of ordinances enacted without regard for the valuable practical experience of recent years. Even where unusually high rails are specified, the T-rail is still the most satisfactory when considered from every standpoint.

A standard T-rail varying in weight from sixty pounds to ninety pounds, considering traffic and team travel as well as number, weight and speed of cars, will meet all conditions.

The sixty-foot rail is better than the shorter one for obvious reasons—the duration of the rail itself, smooth riding surface, ease on rolling stock and the lesser number of joints.

The bonds are one of the most important factors in construction. The protected bond is the most satisfactory and is the only bond that may be considered permanent. In placing bonds the bond terminals and the reception holes in the rails should both be thoroughly tinned. Next, the terminals should be well soldered and then allowed to cool completely before being compressed. The pressure should be applied until after the soldering because of the vast difference in the relative expansion of copper and steel. In this way only can a perfect contact be effected—one that will allow no space for the formation of verdigris, cause no undue loss in the transmission of current and not require further expense in maintenance.

The under-truss or base-supported joint has largely solved the vexatious problem of joints. In the angle-bar and fish-plate joints, with all the protection of spring nut-locks, etc., bolts will stretch with use and the unavoidable stresses will make themselves evident. With the under-truss or base-supported joint the lost motion is to a great extent taken up as it develops. The joint holds the receiving rail rigid and level, thus preventing the pounding and wear on the ends where the rails are most susceptible to wear and need the most protection.

After the subgrade and track have been completed then the entire surface of the prepared roadbed should be covered with a layer of concrete. The concrete mixture should be made of good standard quality of Portland cement in the following proportions: One part cement, three parts clean, sharp sand and five parts clean, crushed stone. This mixture should be used as wet as possible, but care should be taken that the quantity of water is not so great as to cause the cement to be washed away and wasted. When the cement has been thoroughly tamped and rammed between ties it should cover the entire roadbed to a depth of at least six inches; in fact, to as great a depth as the rail height and dimensions of paving material will permit.

The concrete should be given every possible opportunity to set. Where conditions will permit, two or three days should elapse before the paving is placed and then, if possible, a week longer before traffic is opened. This frequently is not the case, but when full ten days' time is given the cement in which to set then the very best roadbed conditions are assured.

Upon the concrete foundation there should be laid a cushion of fine, sharp, clean sand. This should be from one and one-quarter inches to one and one-half inches deep in the centre, to three-quarter inch to one inch deep at the rails, thus allowing a one-half-inch crown.

These considerations contemplate paving with blocks, brick or stone. In fact, paving between tracks, to be at all satisfactory, must be in the form of blocks because repairs will be necessary from time to time regardless of every care that may be taken. A rigid roadbed also must be guarded against.

Vitrified paving brick is the most satisfactory paving material. If nose brick are used next to the rails inside they should be laid as compactly as possible. Every tenth course should be brought to line and a one-inch expansion joint be placed every fifty feet. When the brick have been laid they should be well rolled with a roller weighing at least 1,000 pounds. This forces them to proper surface. The expansion joints should be filled with a mixture of pitch and sand and the entire surface flooded with cement grouting, thus completely filling every crack and crevice.

No matter how light the traffic may be, hard centre special track work will be the more economical in the long run and much more satisfactory in use.

The relative cost of track with material and methods as here described will compare very favorably with any other method that has been attempted when the permanency of this track is considered and the lessened cost of maintenance and wear on rolling stock are credited to the original cost as time elapses.

A paper entitled "Advantages and Disadvantages of Tungsten Lighting to Central Stations" was presented by T. R. Phillips. Mr. Phillips compared the tungsten lamp with other forms of illumination, and said that, in his opinion, the customers should be fully informed regarding the possibilities of the new lamp. He believed that this information should come from the lighting company, rather than from any outside source. If the lighting companies failed to push the new lamp, the consumer would naturally feel that the company was not in sympathy with the high-efficiency unit and was trying to hold off because of a more attractive revenue which was possible with the older forms of lamps. He thought that the tungsten lamp was very valuable in meeting competition and in getting business which was not heretofore available. He cited examples where, by the introduction of the tungsten lamp, dissatisfied customers had been retained. In one case, where a customer had an installation with a total equivalent of forty-nine sixteen-candle-power lamps, he became dissatisfied and threatened to discontinue the use of the electric service. His installation was replaced with tungsten lamps, which reduced the installation to an equivalent of eighteen sixteen-candle-power lamps. The bill was reduced from $28 to $15 per month. While this looked like a loss of revenue it amounted in the end to a loss of only $13; and, in addition, the customer was so well satisfied that he paid for the entire change in installation.

The entire session on Friday morning, September 18, was given up to a discussion of topics of interest to the public utilities operators. President Hegarty opened the discussion on the subject of charging renewals of incandescent lamps to maintenance expense. Within the last few years bankers buying the bonds of electric lighting companies in Arkansas, and trust companies, in underwriting mortgages, were insisting upon a maintenance expenditure of ten per cent in order that the property might be kept in first-class condition. In a great many installations it was difficult to meet this ten per cent charge unless the cost of renewals and similar repairs could be charged in as maintenance. This matter elicited a vigorous discussion, and the consensus of opinion seemed to be in favor of swinging the item for incandescent-lamp renewals into the maintenance charge. In some central stations the cost of free renewals amounted to two and one-half and three per cent. If this cost were charged to maintenance it would facilitate the figuring in of a ten per cent maintenance charge.

Several of the speakers were of the opinion that the renewal of incandescent lamps was practically of the same order as the trimming of arc lamps and the renewing of carbons. There was, however, a considerable difference of opinion, and it was finally suggested that the matter be referred to the National Electric Light Association at a subsequent annual convention.

Another subject which was given considerable discussion was that of public utility corporations dealing with political matters. Of course, where a municipal plant is involved it is a political issue, and some of the members deplored the fact that political interference sometimes took such a turn that the operators were unable to carry out the demands made upon them by the city council. After a lively discussion it was concluded that the opportunity for successful municipal operation was slight, because of the rotation in office. In some of the towns the matter of the municipal lighting property became a direct issue, one party favoring the continuance of the municipal lighting scheme, and the other party favoring selling the property to private individuals. One instance was mentioned of a town where a municipal electric lighting plant supplies the city lighting. On a moonlight schedule it was claimed that the operating expenses were about $39.50 per light. The corporation in this town could not meet this price because the municipal plant was not charged with taxes nor was anything set aside for depreciation.

It was unanimously voted that the present officers of the association remain in office for the ensuing year. Hot Springs, Ark., was selected as the next place of meeting, the date to be decided by the executive committee.

After extending a vote of thanks to the Marion Hotel Company, of Little Rock, and the Little Rock Railway and Electric Company, for courtesies extended during the convention, the meeting was adjourned.

The officers of the association are: D. A. Hegarty, Little Rock, president; J. E. Cowles, Hot Springs, secretary.

Fall Meeting of the New York Electrical Society.

The opening meeting of the New York Electrical Society for the season 1908-09 will be held in the concert hall of Madison Square Garden on Monday, October 12, at 8.30 P. M.

William Maver, Jr., will deliver a half-hour address on "The Dramatic Phases of the Early Cable Work," giving a succinct account of the early progress of submarine-cable laying, leading up to the making and laying of the cables of 1858 and 1866. This address will be illustrated with lantern slides showing the prominent features of this work and those engaged in it.

Through the courtesy of the Electrical Show, the members of the New York Electrical Society will visit the exhibition after the meeting free of charge, and will be welcomed at the society's headquarters in the northeast corner of the building.

Suit has been brought in Common Pleas Court in Cleveland by the Cleveland Railway Company for $220,134 quarterly rent for the street railway lines leased to the Municipal Traction Company. This rent, tendered September 30 by the Municipal Company under condition that the money be used in declaring a dividend to Cleveland Railway stockholders, was refused by the Cleveland Railway under these conditions, formal demand for its payment October 1 being made.

Seeing by Wire.

The problem of seeing by wire, which has occupied scientists and inventors for many years, seems to be in a fair way of being solved, says the *Umschau* (Leipsic), September 12, by a new method recently devised by Mr. Armengaud, the well-known president of the French Aeronautical Society. The property of selenium in changing its conductivity according to the intensity of light rays striking it is made use of in the electrical transmission of an image. In natural vision an image is produced in the eye by the different light values of an object and the problem is, so to speak, to construct of selenium an artificial retina which will receive its impressions from the electrical current variations in a circuit in which it is connected. At the distant end of the circuit the corresponding light impressions must be reproduced by the current variations; but, in order to create an image in the eye, the different light impressions must be produced simultaneously, while those transmitted by wire succeed each other. This difficulty can only be overcome by subjecting the selenium cell to all the light rays emanating from an object within one-tenth of a second, that is, within the time necessary for the retina to be affected by an image. In the receiver the last light impression must arrive before the first one is extinguished. This necessary speed in the transmission and reconstruction of an image has so far been an unsurmounted obstacle. Armengaud's method was suggested by the cinematograph, and is based on the ingenious mechanism by which the films receive their rapid, intermittent motion. He first produces, on the frosted glass plate of a camera, a real image of the object to be transmitted. Then he divides the image into small squares, the light from each of which is thrown on the selenium cell in rapid succession during definite and equal time intervals. The variation in the electric current is produced exclusively by the light emanating from the exposed square, independently of the duration and effect on the selenium cell; this is of importance. All the squares comprising an image are exposed in less than one-tenth of a second. The process is as follows: Two endless bands move in front of the glass plate in the manner of cinematographic films, one in a horizontal and the other in a vertical direction. Each of them is provided with slots at equal distances. At the point where the slots cross each other a square of the image is exposed to the light, and by the combined movement of the two bands a correct succession of the exposed squares is brought about. One difficulty was the well-known sluggishness of selenium to return to its original condition after illumination, which would cause a distortion of the succeeding light impressions, and, in order to prevent this, a series of elements are so arranged that they will be exposed to the light beam in rotation. For the retransformation of the electrical current variations into light effects Armengaud intends to utilize Belin's method together with a Blondel oscillograph and a color scale; that is, the electrical current variations are transmitted to a small mirror in a magnetic field. Light rays are made to strike the mirror and are reflected by a system of lenses to a screen, where they appear, according to the strength of the electric current, as a series of more or less strong light effects in extremely rapid succession; that is, as an image. At the present time Armengaud is engaged in practically testing his apparatus; but whatever his results may be, it appears certain that his labors indicate the solution of this difficult problem.

The Illuminating Engineering Society.

The second annual convention of the Illuminating Engineering Society was held at Philadelphia, Pa., on Monday and Tuesday, October 5 and 6. Headquarters were established at the Hotel Walton, and sessions were held on the morning and afternoon of both days. The following programme was announced:

Monday, October 5, at 10.30 A. M.—Address of welcome, Hon. John E. Reyburn, mayor of Philadelphia. Presidential address, Dr. Louis Bell—A study of the problem of street lighting in its broader aspects, especially with reference to the choice and placing of lamps in their relation to effective illumination. Report of Committee on Nomenclature and Standards, presented by Dr. A. C. Humphreys, president Stevens Institute.

On Monday, October 5, at 8 P. M., the following papers were presented:

"Modern Gas Lighting Conveniences," by T. J. Little, Jr.

"Illuminating Value of Petroleum Oils," by Dr. A. H. Elliott.

"Street Lighting Fixtures: Gas and Electric," by H. Thurston Owens.

"Structural Difficulties in Installation Work," by James R. Strong.

"Architecture and Illumination," by Emile G. Perrott.

On Tuesday, October 6, at 9.30 A. M., the following papers were presented:

"Intensity of Natural Illumination Throughout the Day," by Leonard J. Lewinson.

"The Integrating Sphere in Industrial Photometry," by Dr. Clayton H. Sharp and Preston S. Millar.

"The Ives Calorimeter in Illuminating Engineering," by Dr. Herbert E. Ives.

"Calculating and Comparing Lights from Various Sources," by Carl Hering.

"The Calculation of Illumination by the Flux of Light Method," by J. R. Cravath and V. R. Lansingh.

On Tuesday, October 6, at 2 P. M., these papers were taken up:

"Street Lighting with Gas in Europe," by E. N. Wrightington.

"Design of the Illumination of the New York City Carnegie Libraries," by L. B. Marks.

"Engineering Problems in Illumination," by Alfred A. Wohlauer.

"Intrinsic Brightness of Lighting Sources," by J. E. Woodwell.

"Some Experiments on Reflection from Ceiling, Walls and Floor," by V. R. Lansingh and T. W. Rolph.

"The Relation Between Candle-Power and Voltage of Different Types of Incandescent Lamps," by Francis E. Cady.

Electricity in Mines.

Kurt Perlewitz is the author of a series of articles in the *Elektrotecnische Zeitschrift,* August 20 and 27 and September 3, treating on the electrical equipment of the "König Ludwig" coal mines in Recklinghausen, Germany. There are several power plants operating in parallel, using reciprocating engines, turbines and waste gas engines. The latter are of the four-cycle type and use coke-oven gas. The steam for the reciprocating engines and turbines is generated by means of coke-oven gas, which passes through fire-brick-lined ducts to a bank of boilers of the combined Lancashire and return tubular type. Steam is generated under ordinary conditions at 115 pounds and 570 degrees Fahrenheit superheat. By using the lower section only (Lancashire boiler) the steam is raised to 175 pounds. The second article treats on the switch gear and transformers. The third article covers the description of power plant No. 2, containing reciprocating and gas engines. (Power plant No. 1 contains turbines.) The generators are 500 kilovolt-amperes, 5,200-volt, fifty cycles. In plant No. 2 the double bus-bar system is used, while in No. 1 the ring system is used.

Street Railway Week.

Conventions of the American Street and Interurban Railway Association, the Accountants' Association, the Engineering Association, the Claim Agents' Association, and the Transportation and Traffic Association, Atlantic City, N. J., October 12-16.

THE annual convention of the American Street and Interurban Railway Association and its affiliated and allied associations will be held at Atlantic City, N. J., October 12, 13, 14, 15 and 16. The American Street and Interurban Railway Manufacturers' Association is making great preparations for a magnificent exhibit, which will cover the entire area of Young's million-dollar pier. One hundred and fifty different companies have already been assigned exhibit space. The association booth for the registration and information of delegates and guests to all of the associations will be located at the Boardwalk entrance to the pier. The Manufacturers' association will also have a booth at the same place, which will take care of similar matters relating to the exhibitors and the members of that organization.

All of the meetings of the American association and of the Transportation and Traffic Association will be held in the Greek Temple, near the outer end of the convention pier. The Accountants will hold their two sessions on Wednesday, at the Chalfonte Hotel, and their Thursday and Friday sessions in the Aquarium Court Hall, near the Boardwalk end of the convention pier. The Engineers will hold their Tuesday and Wednesday sessions in the Aquarium Court Hall, and their Friday session in the Greek Temple. The Claim Agents will hold all of their sessions at the Traymore Hotel.

The following programme has been announced:

ACCOUNTANTS' ASSOCIATION.

Tuesday, October 13—2 to 5 P. M.—Registration and badges.

Wednesday, October 14—9.30 A. M. to 12.30 P. M.—Convention called to order. Annual address of president. Annual report of executive committee. Annual report of secretary-treasurer. Paper—"Organization of the Accounting Department of an Electric Railway and Light Company," by A. R. Patterson, general auditor Savannah Electric Railway Company, Savannah, Ga. Report of Committee on Collection of Blanks and Forms, by Elmer M. White, secretary Accountants' Association, Brooklyn, N. Y. Appointment of Convention Committee. New business.

Wednesday, October 14—1 P. M.—"Get together luncheon."

Thursday, October 15—9.30 A. M. to 12.30 P. M.—Paper—"Interline Accounting of Interurban Railways," by W. H. Forse, Jr., secretary and treasurer Indiana Union Traction Company, Anderson, Ind. Paper—"Accounting Methods of a Holding Company," by P. S. Young, comptroller Public Service Railway Company, Newark, N. J. Report of Committee on Standard Classification of Accounts and Form of Report. Report of Committee on International Standard Form of Report. Appointment of Nominating Committee.

Friday, October 16—9.30 A.M. to 12.30 P. M.—"The Effect of Electrification on the Accounting Methods of Steam Railways," by A. B. Bierck, general auditor Long Island Consolidated Electrical Companies, Long Island City, N. Y. Reports of convention committees. Report of Nominating Committee. Election of officers. Installation of officers. Adjournment.

ENGINEERING ASSOCIATION.

Tuesday, October 13—9.30 A. M. to 12.30 P. M.—Registration and badges.

Tuesday, October 13—2 P. M. to 5 P. M.—Convention called to order. Annual address of president. Annual report of executive committee. Annual report of secretary-treasurer. Appointment of convention committees. Report of Committee on Maintenance and Inspection of Electrical Equipment.

Wednesday, October 14—9.30 A. M. to 12.30 P. M.—Report of Committee on Standardization. Report of Committee on Power Generation.

Wednesday, October 14—2 P. M. to 5 P. M.—Report of Committee on Control. Appointment of Nominating Committee. Report of Committee on Power Distribution.

Thursday, October 15—9.30 A. M. to 12.30 P. M.—Exhibition of exhibits.

Thursday, October 15—2 P. M. to 5 P. M.—Inspection of exhibits.

Friday, October 16—9.30 A. M. to 12.30 P. M.—Report of Committee on Car and Car-House Wiring. Report of Committee on Operating and Storage Car-House Designs. Question box.

Friday, October 16—2 P. M. to 5 P. M.—Report of Committee on Way Matters. Report of Committee on Economical Maintenance. General business. Report of Nominating Committee. Election of officers. Installation of officers. Adjournment.

CLAIM AGENTS' ASSOCIATION.

Monday, October 12—9.30 A. M. to 12.30 P. M.—Registration and badges.

Monday, October 12—2 P. M. to 5 P. M.—Convention called to order. Annual address of the president. Annual report of the executive committee. Annual report of the secretary-treasurer. Appointment of convention committees.

Tuesday, October 13—9.30 A. M. to 12.30 P. M.—Paper—"The Organization of a Claim Department for a Small or Moderately Large Company, Including a School of Instruction as a Means of Preventing Accidents," by Francis J. Ryan, M.D., Syracuse Rapid Transit Railway Company, Syracuse, N. Y. Paper—"The Claim and Its Disposition," by Peter C. Nickel, claim agent New York City Railway Company, New York, N. Y.

Tuesday, October 13—2 P. M. to 5 P. M.—Paper—"Uniformity in Claim Department Records and Accounts," by John J. Reynolds, claim agent Boston Elevated Railway Company, Boston, Mass. Paper—"The Duties of Claim Agents and Other Officials of Quasi-Public Corporations to the Public," by Eugene R. Roberts, attorney Knoxville Railway and Light Company, Knoxville, Tenn. Appointment of Nominating Committee.

Tuesday, October 13—8 P. M.—Social smoker and entertainment. (Place to be announced later.)

Wednesday, October 14—9.30 A. M. to 12.30 P. M.—Question box. Discussion—"The Medical Side of the Prevention of Accidents." General business. Reports of convention committees. Report of Nominating Committee. Election of officers. Installation of officers. Adjournment.

TRANSPORTATION AND TRAFFIC ASSOCIATION.

Monday, October 12—9.30 A. M. to 12.30 P. M.—Registration and badges.

Monday, October 12—2 P. M. to 5 P. M.—Convention called to order. Congratulatory address by the Hon. W. Caryl Ely. Annual address of the president. Report of organization meeting. Annual report of the executive committee. Annual report of the secretary-treasurer. Appointment of convention committees. Reports of special committees. Paper—"How Can a Small Road Best Promote Traffic and Increase Its Revenue?" by Ernest Gonzenbach, general manager Sheboygan Light, Power and Railway Company, Sheboygan, Wis. Report of Committee on Training of Employés.

Tuesday, October 13—9.30 A. M. to 12.30 P. M.—Paper—"Carrying of United States Mail on Electric Railways, Its Advantages and Disadvantages, and the Compensation Therefor," by C. H. Hile, assistant to vice-president Boston Elevated Railway Company, Boston, Mass. Report of Committee on Freight and Express. Paper—"Progress to Date in Carrying Freight and Express Matter by Electric Roads—Some Mistakes that Have Been Made and Their Remedy," by C. V. Wood, general freight and passenger agent New England Investment and Security Company, Boston, Mass.

Wednesday, October 14—9.30 A. M. to 12.30 P. M.—Appointment of Committee on Nominations. Symposium—"The Possibilities of a Well-Conducted Publicity Department," by George Sabin Brush, clerk transportation department Boston Elevated Railway Company, Boston, Mass.; B. R. Stephens, general traffic manager Illinois Traction System, Springfield, Ill.; Charles E. Flagg, department of publicity Inland Empire System, Spokane, Wash.; George H. Gall, publicity manager Washington, Baltimore & Annapolis Electric Railway Company, Baltimore, Md.; Charles W. Lamb, advertising expert, Milwaukee, Wis. Report of Committee on Interurban Rules.

Thursday, October 15—9.30 A. M. to 12.30 P. M.—Paper—"The Operation of Multiple-Car Trains on Interurban Roads," by D. F. Carver, receiver Trenton & New Brunswick Railroad Company, Trenton, N. J. Report of Committee on Passenger Traffic. Report of Committee on Rules for City Operation. General business. Report of Nominating Committee. Election of officers. Installation of officers. Adjournment.

The Manufacturers' association has practically completed its plans for entertainment during the convention, and the detailed arrangements will appear in the official programme. On Monday evening occurs the annual carnival of the Atlantic City Business League. On Tuesday evening the annual reception will be held at the Marlborough-Blenheim Hotel. The amateur vaudeville performance will be given at the Savoy Theatre on Wednesday evening, two theatres have been engaged for Thursday evening and a musical entertainment occurs at the Marlborough-Blenheim on Friday evening. In addition, there will be several afternoon entertainments for the ladies during the convention week.

The Conservation and Use of Water-Power Resources.

In a previous article under the above title, in the *Engineering Magazine* (New York), October, the author, H. von Schon, proposed a plan for Federal, state and corporate action in the conservation and development of water-power resources. In the present article the extent of the influence conservation might exercise on national economic conditions is taken up. Mr. von Schon has designed power plants on some of our southern rivers within recent years where the flood-flow volume is 100 times the normal flow. The adaptation of hydroelectric installations to such conditions presents problems that can be met only by special and costly works and safeguards. Great loss of efficiencies of the generating equipment can not be avoided during the periods of excessive fluctuations of flow, while continuous output can be secured only by the aid of large auxiliary power installations. All stream flow has its origin in so much of the precipitation as is not evaporated, this term embracing the quantity of moisture absorbed by vegetation and that which evaporates. The residue of precipitation runs off the surface immediately or sinks into the ground, whence it feeds gradually into the stream channels. The ratio of surface run-off to ground-storage supply depends entirely upon the surface and subsurface characteristics. A forested area, with its deep layer of leaves, brush and humus, is a sponge which becomes saturated with water, and is a natural storage reservoir. The foliage canopy of the trees breaks the force of the downpouring rain, which reaches the ground gradually; and finally the snowfall remains in the forest to melt gradually, and then sink into the ground. Water waste, with collateral flood destructions of life and property through constantly increasing erosions of fruitful top soil, was recognized and acted upon by some of the European countries hundreds of years ago. Switzerland, in 1680, enacted a forest conservation statute. Twenty per cent of the republic's area is in conserved forests, some 2,000,000 acres. The cost of maintenance and supervision is $1.32, and the net revenue $2.25 per acre annually. Germany's forest area is 35,000,000 acres, and its system of forest preservation was inaugurated 150 years ago. France has 23,000,000 acres of forests, all under admirable preserve laws. The combined population of these two countries exceeds that of the United States by about 15,000,000. They now expend annually on forest preservation some $11,000,000, and enjoy a net revenue of about $30,000,000; while the United States forestry expenditures last year aggregated $1,400,000, and the revenue was $130,000. The total forest area of this country aggregates 600,000,000 acres, of which about 150,000,000 acres are now under federal and state forest reserve protection. The total timber consumption to-day is nearly three times the total annual new growth, and water conservation by the aid of the forests does not look very promising for the near future. Prompt relief can be had only by the storing of the largest practicable flood-run-off per cent and the distribution of this quantity during the dry season. With the conserving of the forests and the water-power resources, the country will naturally come back to the greater utilization of its inland waterways. Railroads can not keep up with the enormous rapidity of progress, and to meet the greater transportation requirements of the future, inland water transportation will have to be developed. Inland waterways and electric traction are destined to become the chief transportation methods of the future, and the development of both of these is a collateral consequence of the conservation of water and of the water-power resources.

American Institute of Electrical Engineers Catalogue of Wheeler Gift.

The bibliographical catalogue of the books, pamphlets and periodicals of the celebrated Latimer-Clark collection presented by Dr. Schuyler Skaats Wheeler to the American Institute of Electrical Engineers has just been completed and is about to go to press. This critical catalogue has been in preparation for the past six years under the direction of W. D. Weaver, with the collaboration of Brother Potamian, of Manhattan College, and a number of other authorities here and abroad. The expense of this unique work has been defrayed by Andrew Carnegie. As soon as the book comes from the press it will be distributed to the members of the Institute, who, according to the deed of gift of the library, are entitled to the catalogue.

THE DISCOVERY AND DEVELOPMENT OF THE LAWS OF THERMO-DYNAMICS.[1]—III.

BY DUGALD CLERK.

(Concluded.)

We now come to Siemens's paper "On the Conversion of Heat Into Mechanical Effect," and for the first time we find the engineer guided by an intelligible principle. Siemens discussed the material theory of heat, and accepted unreservedly the dynamical theory, for which he gives a large measure of credit to Joule. This is the first of the institution papers in which I find the name of Joule. Siemens mentions Carnot, Clapeyron, Holtzman, of Mannheim; Joule, Helmholtz, Meyer, Rankine and Professor Thomson. Curiously enough, although Siemens mentions Carnot and the other philosophers who dealt with the Carnot principle, including Thomson, he does not appear at this date—May 17, 1853—to have realized himself the effect of the law of Carnot upon the theory of the heat engine. He clearly appreciated the first law, and gives the mechanical equivalent of heat as determined by Joule at 770 foot-pounds, and by Thomson's formula as 772 foot-pounds, but in his discussion of the principles of the heat engine he is of opinion that a perfect engine is ideally possible giving 770 foot-pounds for each Fahrenheit heat unit employed. This is clear from a table found on page thirty-three of the paper, which I reproduce:

SIEMENS'S TABLE OF 1853.

Description of Engine.	Theoretical Performance in Foot-Pounds.	Actual Performance in Foot-Pounds.	Actual Performance in Pounds of Coal per Horse-Power per Hour.
A Boulton and Watt condensing engine, low pressure	51.8	29	8
The best Cornish engine	158.8	82	2.38
Combined steam and expansive-ether engine	150	75	3.09
The expansive-air engine	91	35	6.63
Stirling's engine	130	65	3.57
Ericsson's engine	196	65	3.57
A perfect engine	770	385	0.60

He apprehends the mechanical equivalent of heat, but he still appears under the impression that if heat be added to a certain upper temperature and expansion take place until the original temperature is reached, then he has a perfect engine indicating the full result of Joule's mechanical equivalent. He sees, however, that the old theory of the regenerator is quite wrong. He states:

"The cause of the failure of Mr. Stirling's engine in practice may apparently be traced chiefly to insufficiency of heating surface, occasioned apparently from misapprehension of the principle involved, it having been thought that the same heat would serve over and over again to produce power, and that the necessary expenditure of heat consisted only in the mechanical loss by imperfect action of the respirative plates, which were approached to each other to the utmost limits consistent with an unobstructed passage of the air. By the aid of the dynamical theory of heat it has been shown that there is another and far more important expenditure of heat which should have been provided for."

Siemens, in the discussion, rightly upheld the regenerator as useful, but saw that there were limitations to its use. Mr. Hawksley contended that the regenerator was useless. Mr. Pole considered that the regenerator was useful, but he did not definitely adopt the mechanical theory of heat. He stated:

"It must be allowed that the general action of caloric in producing power was still involved in much obscurity. The heat was often considered in reference to its quantity only, but it was certain also that its intensity performed a very important part; and it had even been surmised that power might be obtained by the reduction of intensity alone, without any change of quantity."

Armstrong concurred with Siemens and Pole. He believed in the utility of the regenerator, limited as described by both. Edward Woods certainly understood Siemens to have given 772 foot-pounds as the efficiency of an ideal heat engine, because he stated that this showed there was still great room for improvement in engines. E. A. Cowper had clear ideas. He said:

"Steam, or gases, in expanding, and so giving out power, lost heat. Part of the sensible heat became latent in the production of power, and this heat could only be recovered by expending the power already produced in again condensing the steam back to its original bulk, when the latent heat again became sensible."

This discussion, then, puts us in the position of engineers at the date of the last meeting referred to—May 17, 1853. Of all the distinguished engineers who spoke, Siemens alone had thoroughly apprehended the value of Joule's results, and understood the full bearing of the mechanical equivalent of heat. He had not, however, understood Carnot's reasoning on the Carnot cycle, or Thomson's deductions from Carnot. He was under the impression that heat added in any way to a working fluid, raising the temperature, could be entirely converted into work by a sufficient expansion. He had not appreciated that, even if expansion be carried far enough to reduce the temperature to the original temperature before heat addition, yet complete conversion of the entire mechanical equivalent was impossible. When so able a man as Siemens had at this stage only reached partial enlightenment, it was evident that much hard work and clear thinking required to be done before a well-founded theory of heat motive power could be obtained. The data for such a theory were accumulating; and one of the most interesting circumstances connected with these Institution of Civil Engineers' papers was a communication from M. Regnault to Colonel Sabine, treasurer of the Royal Society, dated April, 1853, which was read at the meeting, in which Regnault stated that:

"He was about to publish immediately a series of elaborate experimental researches on various subjects connected with the effects of heat on elastic fluids, the results of which would solve many questions long in dispute, and by means of which engineers might accurately calculate the effect of a given amount of fuel, in whatever way it was applied. M. Regnault communicated in anticipation that he had arrived at the number 0.237 for the specific heat of air at constant pressure, and at 0.475 for that of steam under atmospheric elasticity, the specific heat of water being taken in each case as unity."

True to his word, Regnault produced his admirable investigations and succeeded in solving many problems; but he did not settle the questions to the extent he had hoped. Even at the present time doubt arises as to the very values he gave for the specific heat of air and steam. The problem proved much more difficult than he had anticipated, and for modern-engine purposes it can not be considered as wholly solved now—fifty-five years later.

This description of the position of the hot-air engine, as shown by the opinions of eminent engineers, is most useful as proving how much practical men were in need of the work of Thomson and Joule. It is not surprising that, of all the engineers present, Siemens appeared to be alone in thoroughly grasping the new ideas. Thomson's own conversion from

[1] Presidential address delivered to the Engineering Section of the British Association for the Advancement of Science, Dublin, September 3.

the material theory of heat to the dynamical theory was not complete until 1851, and although he had then succeeded in reconciling the ideas of Joule and Carnot, it is not to be wondered at that engineers two years later had not quite succeeded in grasping the combination of the two laws. This combination, however, supplied engineers with a new and accurate standard of measurement for studying and improving upon their heat engines, and they were by no means slow in grasping the help thus offered them by the abstract scientific man. The broad laws of thermodynamics have placed the theory of the heat engine in a position of certainty which was much needed. It would be a mistake to assume, however, that even the determination of the mechanical equivalent of heat and the second law of thermodynamics expressed in terms of an absolute thermometric scale had solved all the difficulties of the engineer desiring to determine the efficiency of his heat engines. Thomson, Joule, Rankine and their great Continental colleagues, it is true, settled once and for all the broad laws of thermodynamics, but the Carnot cycle is a cycle which is, as has been repeatedly shown, an impossible one in practice. Accordingly, actual engines have to operate upon imperfect cycles. The theory of these imperfect cycles has been worked out mostly during the last twenty-five years, although Rankine made a beginning in dealing with the theory of the Joule air engine. For the first time he showed the existence of what might be termed a cycle of constant efficiency in the case of the Joule air engine. Assuming constant specific heat for the working fluid, he calculates the efficiency of what we now call a constant-pressure air engine between certain limits of temperature, and he gives the efficiency of the fluid where U = energy exerted, and H_1 = heat received, and r = ratio of compression and expansion:

$$\frac{U}{H_1} = 1 - \frac{1}{r^{0.408}};$$

that is, he indicates in this formula that the thermal efficiency is independent of the maximum temperature as long as that maximum temperature exceeds the temperature of adiabatic compression. He makes no statement, however, that this engine is within a certain range independent of the maximum temperature—that is, that increasing maximum temperature does not increase efficiency. Subsequent work has shown that, on a simple assumption, such as constant specific heat, many engine cycles exist of a practicable nature having high theoretical efficiencies where the theoretical efficiency depends on one thing only—the ratio of compression. Some misunderstanding has arisen with regard to these imperfect cycles, and it has even been thought that such imperfect cycles would be contrary to the second law of thermodynamics. Lord Kelvin himself was of this opinion in 1881. I vividly remember a conversation I had with him at the Crown Iron Works, in Glasgow, over the results I had obtained from one of my early gas engines. I had then come to the conclusion that the Otto cycle, as ordinarily operated, was a cycle of constant efficiency, and I explained this to Lord Kelvin. He had not followed such cycles, and his view then was that no such cycle could exist, because he thought it was contrary to the second law of thermodynamics. Some idea of this kind has been held by many scientific men and has prevented the minute investigation of imperfect cycles of different kinds because of the feeling that the whole question of efficiency was entirely settled by the nature of the temperature limits—that is, by the maximum and minimum temperatures at the disposal of the engineer. It is true that these values, as has been shown, must always determine the extreme limit of possible efficiencies between certain temperatures, and in cycles of constant efficiency the particular efficiency of the cycle is always less than the efficiency of a Carnot-cycle engine working between the same limits of superior and inferior temperatures. The investigation, however, of these imperfect cycles is much more difficult than the broad investigation of the general thermodynamic laws because it requires accurate knowledge of the properties of the working fluid dealt with under conditions rendering observation extremely difficult. The modern internal-combustion motor is the successor to the air engine so fully discussed by eminent engineers of fifty-five years ago; and the forebodings of even so eminent a man as Faraday as to its ultimate success have proved unfounded. Great difficulties have been encountered and many discrepancies have had to be explained, but a minute study of the nature of the working fluid has rendered it more and more possible to calculate the efficiencies to be expected under practical conditions. At the present time we can deal with almost any cycle or any working fluid with some fair approximation to an accurate result. Much work, however, is required before all problems of the working fluid can be said to be solved with regard to any heat engine. Indeed, it may be said that under modern conditions of the use of steam even the properties of the working fluid—steam—have not yet been satisfactorily determined. The mere question of specific heat, for example, of steam and its variations of temperature and pressure is now under review, and important experiments are in progress in Britain and on the Continent to determine those properties. The properties of the working fluid of the internal-combustion motor are also the subject of earnest study by many Continental and British investigators. Notwithstanding all the perplexities involved in the minute study of the imperfect heat-engine cycles, we are in a very different position to-day compared with the engineer of 1853. We know all the broad laws as to the conversion of heat into work or of work into heat; and, numerous as are the problems yet to be solved, we at least profit by the guiding light set out for us by Kelvin, Joule and Rankine.

Proposed Extension of Electric Railway in Tokyo.

Consul-General Henry B. Miller, of Yokohama, reports the following notice of a proposed extension of electric railway in Tokyo, Japan, which should be of interest to American manufacturers of electrical railway materials:

It is stated that the Keihin Electric Company has practically succeeded in obtaining from London capitalists a loan of 1,000,000 yen ($996,000) wherewith to build a line from Aoyama terminus of the Tokyo Railway to Shingawa. Official permission was obtained some time ago, and the only question that remained was that of finance. The loan is to carry six per cent interest and the company will receive ninety-one yen ($86.27) per bond. It is said that this company intends to double its Omori Shingawa line with a view to the probability that the fisheries section of the proposed Japanese exhibition will be established at Haneda.

Another Swiss-Italian Tunnel.

Dispatches from Geneva state that a company of international financiers has received permission from the Swiss and Italian governments to bore another tunnel through Mount Blanc. On the Swiss side it will start at Martingly, and the Italian outlet will be near Courmayeur. The distance between these points is about twenty-eight miles. It is estimated that the work will take three years, and cost about $14,000,000.

ELECTRICITY IN THE PRODUCTION OF SPELTER AND SULPHURIC ACID.

THE PLANT OF HEGELER BROTHERS, DANVILLE, ILL.

The plant of Hegeler Brothers, smelters of zinc and manufacturers of sulphuric acid, is located in Vermillion County, Illinois, about four miles from the centre of the city of Danville. It is located in the midst of the Danville coal field. The coal under the extensive factory property has never been touched and Hegeler Brothers have acquired extensive coal rights under adjoining property.

The factory is designed for the production of spelter and for the manufacture of sulphuric acid. The ore is mainly purchased in the Joplin fields and brought to the plant in a concentrated form. The anthracite screenings must, of course, be brought from the East, but the bituminous coal which is used so largely in the process is at hand.

The owners of this plant were both connected, for many years, with the Matthiessen & Hegeler Zinc Company, at La Salle, Ill. This latter plant was the first manufactory of spelter and of zinc plate in this country. E. C. Hegeler, who brought the processes from Germany originally, and who is still at the head of the La Salle plant, is the inventor of practically all the modern processes for the manufacture of zinc. He developed the Hegeler calcining kiln which entirely revolutionized this part of the process.

The Danville plant includes many of the features which were developed in the plant at La Salle, but also embodies many improvements designed by Julius W. and Herman Hegeler.

The power plant is located near the centre of the buildings and comprises a boiler room and engine room, the latter of which is built of reinforced concrete with concrete roof supported on steel trusses. From the power plant live and exhaust steam are carried to the pottery building where they are used for drying; compressed air is taken to the various buildings, exhaust steam is run to the repair shop for heating purposes and the great quantity of the exhaust is carried to the acid works where it enters into the manufacture. The main exhaust line to the acid works is on eight-inch spiral pipe insulated with magnesia and protected by a form of ready roofing which protects the covering from the weather. This line is carried in part on "A" frames shown in one of the illustrations, on which frames are also carried the cross-arms for power distribution.

The boiler room at present contains two Stirling boilers, each of 250-horse-power capacity, equipped with Green chain-grate stokers. The plan contemplates the ultimate installation of four additional boilers of the same size and type. There is no use of waste heat in this plant. The chimney is of radial brick and was built by the Heine Chimney Company. It has an inside diameter of seventy-two inches and a height of 150 feet. The boiler room contains a Cochrane open feed-water heater and two centre-packed Platt Iron Works duplex feed pumps. There is no coal-conveying machinery, the fuel being brought into the boiler room on an elevated track and shoveled by hand into the stoker hoppers. Ashes are discharged into the hoppers below the boiler-room floor in a tunnel running the length of the boiler house. From this tunnel they are removed by means of horse-drawn trucks running on tracks.

The electrical equipment in the engine room consists of two three-phase, sixty-cycle National Brake and Electric Company revolving-field alternators operating at 150 revolutions per minute and delivering current at 440 volts. This voltage is maintained for all power service. For lighting service voltage is reduced to 110 at different points on the job. These generators have a capacity of 300 kilowatts and 200 kilowatts, respectively. The engines driving the generators are of the Ball Engine Company's simple four-valve type, the larger of the two machines having valves in the heads and the smaller valves in the barrel. The exciters are belted to pulleys on the engine shafts. The air equipment consists of two steam-driven Ingersoll-Rand machines, the main compressor having compound steam and two-stage air with a capacity of 500 cubic feet per minute at 100 pounds pressure. The reserve machine is of the straight-line type with a capacity of 250 cubic feet. The engine-room floor is approximately eight feet above the boiler-room floor, and the basement of the engine room contains the pump for water supply, traps, oil separators, drains, etc., and the oil filters. The supply of clean oil for the plant is contained in a steel tank suspended at the ceiling of the engine room. Oil is delivered into this tank from the filters by means of two duplex Warren steam pumps with cylinders three inches by two inches by three inches. From this tank oil is delivered through a system of piping to every bearing in the power plant; from each bearing oil drains to a

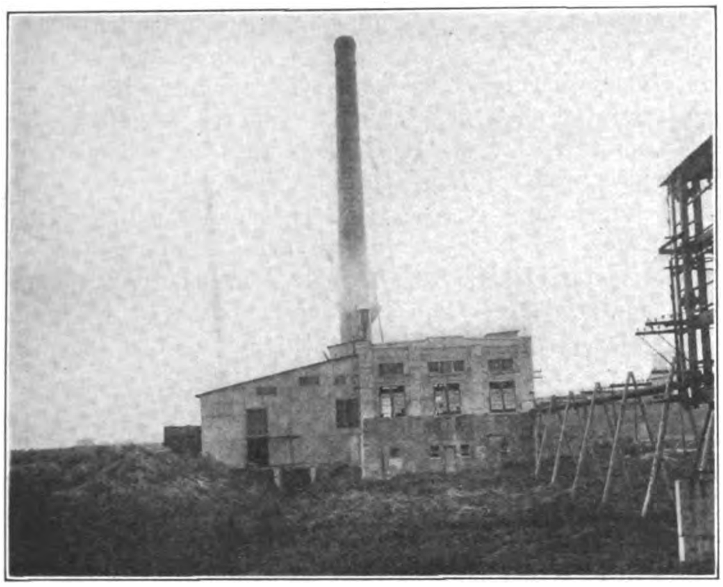
filter in the basement. All cylinder oil for steam and air cylinders, including the pumps, is handled by means of force feed lubricators, independently operated.

The switchboard, which was built by Lounsbery & Eaton, of Chicago, is of simple construction. It is built of blue Vermont marble and is equipped mainly with Westinghouse indicating and integrating instruments. The switchboard is mover outside of the power plant being a gasolene engine in the repair shop which is capable of running the machinery therein and of furnishing light to the shop through a one-and-one-half-kilowatt generator.

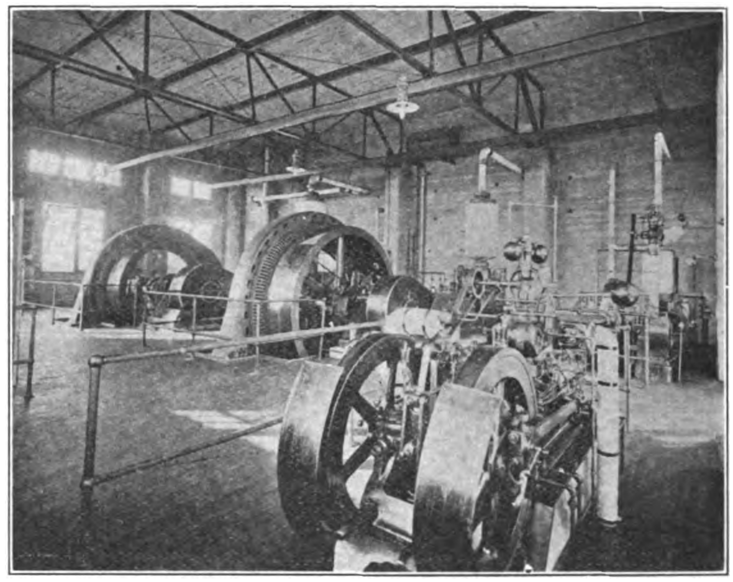
The motors throughout the property are of the General Electric type K pattern and are of varying capacity from five horse-power to seventy-five horse-power. The largest motor is used in the pottery building in the manufacture of retorts

The principal contractors on this work were as follows:

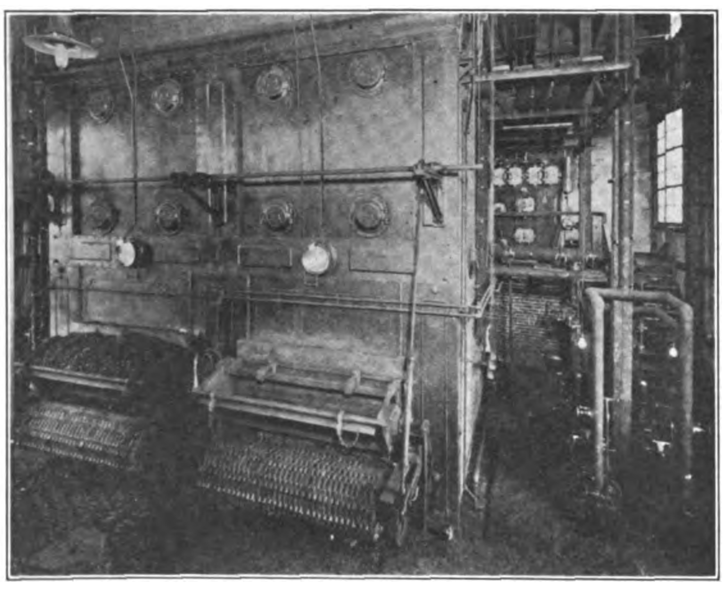
Boilers—Stirling Company (B. & W.). Pumps—Platt Iron Works Company. Chimney—Heine Chimney Company. Lightning protection—Carl Bajour. Engines—Ball Engine Company. Generators—National Brake and Electric Company. Switchboard—Lounsbery, Eaton & Company. Wiring—Freeman, Sweet & Company. Motors—General Electric Company. Steamfitting—Thomas & Smith.



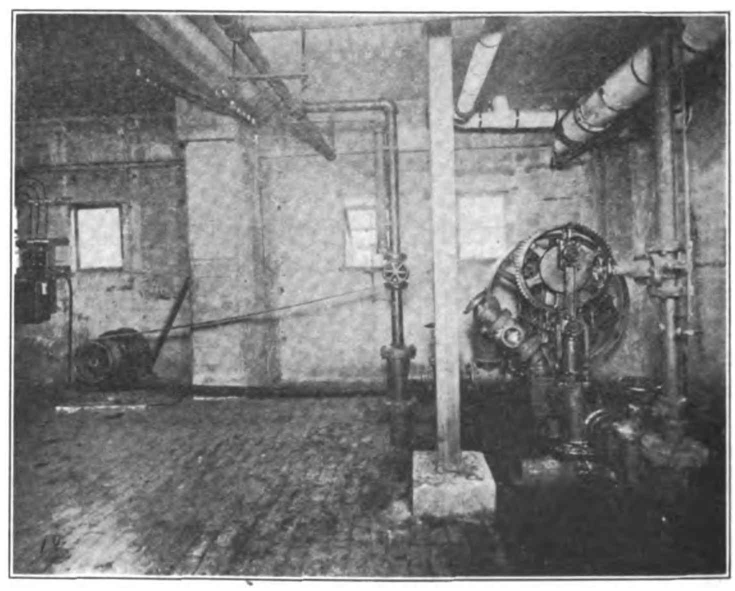
Side View of the Power Plant. Engine Room at Right and Boiler Room at Left of Picture. The Steam and Air Lines Running to the Acid Works Are Shown



View in the Engine Room. Straight-Line Compressor in the Foreground, 200-Kilowatt Unit in the Middle of Room, and 300-Kilowatt Unit at the Left.



Front of Boilers, Showing Stokers; Feed Pumps and Heaters to the Right.



Motor-Driven Triplex Pump Supplying Water to the Elevated Tank.

equipped with a Tirril voltage regulator. A noticeable feature of the plant is the small steam piping. Each engine and compressor is provided with a large receiver separator while the largest steam line in the installation has a diameter of four and one-half inches.

All power is generated in one building which is somewhat contrary to the usual practice in smelting plants. Motors are used for all machinery both in and outside of the power-house, the only prime and condensers for the furnaces. There are two fifty-horse-power motors used in supplying air to the furnaces.

The acid works, which is one of the largest buildings shown in the general view, consists of a large steel structure which is almost entirely filled with another building made entirely of lead. This building contains very little power, one application being a drive to a fan which handles acid fumes and which is built, with the exception of a portion of the shaft, entirely of sheet or cast lead.

Pipe covering—Western Roofing and Supply Company. Feed-water heater—Harrison Safety Boiler Works. Steam and oil separators—Harrison Safety Boiler Works.

The masonry work of the plant, including all building and foundations, was done by the owners. The design of the factory as a whole and in nearly all details was the work of Hegeler Brothers. The power plant and power transmission was done by W. L. Fergus & Company, Chicago.

RECENT ADVANCES IN STEAM TURBINES.[1]

BY GERALD STONEY.

Two years ago I had the privilege of reading a paper on "Steam Turbines" before this section at the York meeting, but in view of the very rapid development of the steam turbine, both on land and for marine propulsion, it may possibly be excused if the same subject is once more brought before you. On land the progress of the steam turbine is to be seen in all directions, and one thing which is especially remarkable is the rapid increase in size. Eight years ago the largest one made, which was considered an immense machine at the time, was for only 1,000 kilowatts, and now there are large numbers ranging from 5,000 kilowatts to 8,000 kilowatts running and under construction. Steam turbines of large size may be roughly divided into two classes, as the Laval turbine with a single reaction wheel requires gearing and is impracticable for large sizes. These two classes comprise, firstly, the Parsons turbine, in which there is both action and reaction, and the expansion takes place equally in the moving and fixed blades, and secondly, those in which the whole of the expansion takes place in the fixed blades, the velocity of the steam being taken up without expansion by the moving blades. This latter class can then be subdivided into those in which, at each stage, there is only a single row of moving blades as in the Rateau and Zoelly turbines, or one in which there are several rows of moving and fixed blades in each stage, which take up the velocity without any additional expansion, as in the Curtis. There are again various combinations, consisting of mixtures of one or more classes, but none of these have as yet been manufactured to any large extent. The oldest type, and one which is more in use than any other, is the Parsons, but in America the Curtiss has been manufactured in large numbers, and on the Continent the Zoelly, Rateau, and A.E.G., although both in America and on the Continent the Parsons has taken a leading position.

Hand in hand with the development of the steam turbine has gone the development of the various machinery to be driven by it, and in this direction electrical machinery has been prominent. For many years continuous-current turbo-dynamos were looked at askance by engineers on account of commutation troubles, for it is easy to see that the ordinary constants applicable to slow-speed dynamos to secure sparkless commutation are far exceeded when the speed is raised to that of turbine-driven dynamos. On this account it was early seen that some sort of compensating winding to improve the commutation and compensate for the reaction of the armature was necessary. Commutating poles alone have not proved satisfactory in practice, there being nearly always considerable difficulty in securing good commutation with them, and, as a consequence, commutating poles combined with compensating windings—the commutating poles giving the reactance voltage necessary for commutation and the compensating winding compensating for armature reaction—have been adopted by many firms. But even better commutation can be secured by a compensating winding alone, in which the ampere-turns of the compensating winding exceed the ampere-turns of the armature to such an extent as to give a commutating field in the gap between the pole-pieces. Such compensating winding is generally chiefly concentrated on the pole-pieces, and is made with from two to two and one-half times the number of ampere-turns of the armature, in order both to compensate for leakage and to give a good commutating field; and since this method of compensating has no iron commutating pole, it has the advantage that there is no self-induction to cause time lag at sudden changes of load; and, as the field of the gap between the poles is entirely in air it instantly responds to changes of current in the compensating winding, and thus the sparking found when there is a sudden change of load with commutating poles is avoided, and the risk of a flash-over largely reduced. Also, since there is no iron to become saturated, the commutating field is always strictly proportional to the load, and thus the trouble due to saturation, causing sparking at some loads and not at others, is avoided. This advantage is specially prominent where the dynamo is required to give varying voltages and to commutate at any of them without outside adjustment of the compensating windings by diverters or otherwise. The adoption of these devices has made it possible to make turbo-dynamos of large size, and now as much as 1,500 kilowatts is put into a single armature, whereas before such compensating devices were adopted 500 kilowatts was the maximum, and even then the commutation was anything but satisfactory.

In turbo-alternators there is practically now—except for small sizes and low voltages—one standard pattern—that is, a revolving field rotating inside a stator. In the stator there is little variation in design, except in regard to the ventilating arrangements, which have to be very ample on account of the comparatively large quantity of heat to be removed from a small volume. One point which has received great attention in recent years is the staying of the end windings of such alternators, it having been found that, owing to their great length, when a "short" took place the stresses on the winding were such as to break the insulation and cause disaster. The amount of these forces has been vastly more than was ever anticipated, and if the windings are not thoroughly stayed, such movements may be set up as to cause disaster. In the rotors there are two prominent types, the barrel and the salient pole, and much discussion has ensued as to the advantages of the one or the other. After considerable experience of both, on the whole I may say that at present I prefer the salient-pole type. Ample ventilation is much easier to provide for, and improvements made in protecting and supporting the field-coils of this type of rotor have resulted in a design giving great reliability with the maximum use of the space available. One improvement has been enclosing every coil in a tight sheath of sheet steel, so that any movement which may take place, due to centrifugal force, is between the steel sheath and the body of the rotor, and thus the insulation is protected from any rubbing which might cause it to be cut through and, consequently, break down. Voltage regulation of alternators is also of considerable importance, as owing to the inductive load required by induction motors there is a heavy demagnetizing effect on the rotor and consequent drop of voltage when the load rises. Several methods have been proposed for compounding alternators, most of them requiring a separate commutator or moving contacts altering the resistance of the exciter or main windings, but a method of compounding alternators has recently been brought out which is being largely used with good results. In this apparatus the current supplied by the machine is made to act on the exciter field system in such a way as to reduce the leakage, artificially increased in the first instance, and so raise the voltage of the exciter and increase the excitation of the alternator, so that any desired amount of compounding required can be obtained. This arrangement has been recently de-

[1] Paper read before the British Association at Dublin.

scribed in a paper before the Institution of Electrical Engineers.

The other applications of the steam turbine, such as driving air-compressors and pumping water, have also been largely extended during the last few years, and especially prominent in this direction has been the application of turbo-blowers to blast-furnace work, some having been recently installed for as much as 50,000 cubic feet of air per minute at ten pounds to fifteen pounds pressure. In this connection it may be mentioned that a very usual size, which is for about 20,000 cubic feet, weighs about twenty-five tons, and that an ordinary reciprocating blower of equal capacity weighs about 450 tons, or about eighteen times as much as the turbo-blower.

In many parts of the country reciprocating engines are running non-condensing, and it has now been found that the exhaust steam from them is of great value. Such exhaust steam can not be practically utilized by reciprocating engines on account of the huge size and volume of the cylinders required, but it is quite otherwise with the steam turbine, where the large volumes of the low-pressure steam are exactly what are required for the highest economy. These considerations have led to the introduction of exhaust-steam turbines, taking steam at atmospheric pressure and exhausting into a condenser. When it is remembered that there is as much power in the steam from atmospheric pressure down to twenty-seven and one-half inches as there is from 150 pounds down to atmospheric pressure, it is easily seen that the power of a non-condensing plant can be doubled by the addition of an exhaust-steam turbine and condenser, and in cases where there is not a supply of cooling water improvements in cooling towers have enabled them to be put up both cheaply and well. In this connection the use of intermittent supplies of exhaust steam, such as that obtained from engines running intermittently, as in rolling mills or winding engines at collieries, has received a great impetus by the utilization of thermal accumulators, in which the intermittent supply of steam is alternately condensed and re-evaporated, so that a constant flow is obtained for use in the exhaust-steam turbine. And yet another refinement has been introduced by the use of mixed-pressure turbines, in which there is a low-pressure part sufficiently large to give full power when working with exhaust steam, and if the supply of this fails a high-pressure part is brought automatically into action using steam direct from the boilers, and thus there is economical running, whether the reciprocating engines supplying the exhaust steam are working or not.

In all turbines the question of vacuum is a very important one, and various improvements have been made in condensers to enable higher vacua to be obtained. The importance of this will be seen when it is remembered that in the average steam turbine one inch of vacuum is equivalent to from four to seven per cent of steam consumption—or, in other words, it may be taken that for every three degrees Fahrenheit by which the temperature, due to the vacuum, is reduced a gain of steam consumption of one per cent is made. In this connection increase of circulating water is very important. A very usual amount is about thirty times, but if this increased to forty-five the gain in consumption is four per cent, and if increased to sixty-five times a further gain of two per cent is made. As a rule extra circulating water can be pumped without much difficulty, the extra power required for this being very small, but generally the temperature of the inlet to the condenser is fixed by the supply of water available. The great desirability, then, in a condenser is to obtain the temperature due to the vacuum as close as possible to that of the water leaving the condenser, as, of course, the maximum vacuum possible is that due to the temperature of this water. In ordinary condensers it is generally found that this difference amounts to twenty degrees to twenty-five degrees Fahrenheit, and among the various arrangements to reduce this may be mentioned dry-air pumps, and also the arrangement of baffles and pumps in the "Contraflo" condenser. But a method which has been very satisfactory in practice is what is called a "vacuum augmentor," which is simply a small jet of steam drawing the air and vapor from the condenser, and delivering it through a small auxiliary condenser to an ordinary air-pump, so that while there may be, say, a vacuum of only twenty-seven and one-half inches at the air-pump, twenty-eight and one-half inches or twenty-nine inches may be attained in the main condenser. Such an appliance is especially valuable when, as is often the case on board ships at sea, the system has considerable air leaks. With this arrangement the difference between the temperature of the water leaving the condenser and that due to the vacuum can be reduced to about five degrees or six degrees Fahrenheit, and this when condensing up to twelve pounds of steam per hour per square foot of condenser. As will be seen, this shows an economy in the turbine of some six per cent in steam consumption above an ordinary condenser, and when it is remembered that the steam jet of the augmentor uses only about 0.6 of one per cent, or only one-tenth of the steam consumption gained, it is easy to see that a great benefit is derived from the use of such an arrangement.

In marine work the development of the steam turbine also is very rapid. Two years ago the great express Cunarders Lusitania and Mauritania were only in process of construction; now they have proved themselves to be the fastest liners afloat, and it is pleasing to note that the turbines of these great ships have proved most satisfactory on service. It was a great step from the 8,000 horse-power of a cross-channel steamer, which was the largest that had been made at the time these boats were designed, to the 65,000 horse-power of these express Cunarders, and reflects great credit on the courage and foresight of the Cunard company, and also on the various contractors, designers and engineers engaged that they have made such a great step in advance without, as many people prophesied, building another couple of Great Easterns. More mistakes have been made in going from a small to a large thing in engineering than in anything else, but the various pitfalls which awaited those responsible have been successfully avoided. It is also interesting to note that the turbines proved themselves to be very economical, a consumption of 12.77 pounds per shaft horse-power having been attained as an average of the whole voyage across the Atlantic with about 150 pounds pressure at the entrance of the turbine, and a vacuum of 28.3 inches, barometer thirty inches. At present all cross-channel steamers in hand are being fitted with steam turbines; the whole of the ships in the Admiralty programme have also turbine engines, and every one knows what a success the Dreadnought and the Indomitable are, they being respectively the fastest and most powerful battleship and cruiser afloat.

Hitherto the link supplied between the steam consumption in a marine engine and the horse-power developed, which is represented by the indicated horse-power, has been missing in a turbine, but the introduction of the torsion meter, which measures the horse-power passing through a shaft by the amount of torsion caused, has supplied this missing link most satisfactorily. The introduction of this has been chiefly due in this country to the enterprise of Messrs. William Denny & Brothers, of Dumbarton, and on the Continent to Mr. Frahm, of Messrs. Blom & Voss, of Hamburg, both of whom on slightly different lines have worked out torsion meters which have proved very satisfactory in practice. This has enabled the various losses between the power in the steam and the power required to propel the ship to be even better located than they are in the case of a reciprocating engine where the indicated horse-power does not take into account the friction of the engine.

The steam turbine up to the present has been almost entirely used for ships of seventeen and eighteen knots and above, and, in fact, it may be generally said that about fifteen knots is the lowest speed of vessel at which the turbine can satisfactorily compete with the reciprocating engine as regards economy. The difficulty of the problem lies in the fact that at low speeds the screws have to be made to revolve at small revolutions, and at the same time the horse-power required is moderate, and thus the turbines have to be very large and heavy, and, besides this, the blades are so short that the loss by leakage is excessive. These considerations have led to the combination of a reciprocating engine for the high-pressure part of the range where the volume of steam is small, and where the reciprocating engine is working exactly under the conditions for the best economy, and a turbine for the low-pressure part of the range where the volume of steam is large, and where, therefore, the turbine is working under the very best conditions, and such an arrangement gives advantages over either the turbine or the reciprocating engine for moderate speeds, and, in fact, it is anticipated that an extra economy of about fifteen per cent can be attained in this way. The advantages of such an arrangement were first pointed out by Mr. Parsons in 1894, but has only recently been put into practice. Many various arrangements and combinations are possible, but that which appears to be most generally favored is to have twin reciprocating engines, each driving their own screws, exhausting into a single turbine driving a centre shaft. The reciprocating engines exhaust at about atmospheric pressure, and the turbine used the expansion from that pressure down to the vacuum of the condenser, which may be twenty-eight inches or twenty-eight and one-half inches. For maneuvering or going astern the reciprocating engines are used. At present two large Atlantic liners are being built with the above arrangement for the Atlantic service, but it may be mentioned that the destroyer Velox, made in 1903 by the Parsons Marine Steam-Turbine Company, Limited, for the British Admiralty, was the first ship fitted with such a combination, she having small reciprocating engines which were coupled on to the main turbines for cruising speeds, and at such speeds she proved exceedingly economical. At high speeds the reciprocating engines were disconnected from the main turbines, which were alone used.

It may be mentioned that eight years ago there were only 25,000 horse-power of marine turbines afloat; two years ago there were 800,000 horse-power, and now there are over one and three-quarters millions completed and under construction.

In this short paper I have endeavored to give an idea of the exceedingly rapid progress of the steam turbine and its applications. Whether in future the progress will be equally as rapid is difficult to say, but so far as can be seen at present there is no sign of saturation in the curve of progress.

Brooklyn Edison Forms State Branch of the National Electric Light Association.

A meeting of the employés of the Edison Electric Illuminating Company of Brooklyn, N. Y., was held at the Edison Club Rooms, Johnson Building, Brooklyn, on Monday, September 28, preliminary to the formation of a company branch of the National Electric Light Association, in pursuance of the Henry L. Doherty amendments to the constitution of the national association made at the spring convention in Chicago, Ill.

This preliminary meeting, which was attended by about eighty employés, was presided over by W. F. Wells, general superintendent of the company, who explained the individual and co-operative benefits to be derived by membership in the national association through the company branch.

It was pointed out that this was an opportunity for self-improvement and for broadening through association with others in various branches of the industry, and that it could not fail to be of service in personal development and in bringing about recognition of talent within the ranks of the Brooklyn organization. Mr. Wells stated that membership would be entirely a matter of choice and that positively no pressure whatever, other than moral suasion, would be brought to bear upon employés to induce them to join. W. W. Freeman, general manager of the company, also addressed the gathering and indicated that membership in the company branch would help to keep employés posted as to up-to-date practice in the different departments of electrical activity and would tend to make their services more valuable to themselves and to the company.

On Friday, October 2, an organization meeting was held, Mr. Wells presiding, and the following officers for the company section were elected: President, G. S. Knight; vice-president, D. D. Sharkey; secretary, E. A. Baily; treasurer, Irving Bugg. Executive committee: W. J. Walsh, G. E. McMullen, E. W. Kells, C. A. Graves, W. Uckele, C. W. Simpkins, G. Valentine, H. B. Pope, E. B. Rannells, G. S. Knight, D. D. Sharkey, W. W. Freeman, and W. F. Wells, *ex officio*.

The men are enthusiastic over this enterprise and already 136 have become members. Ambitious plans are being laid; several meetings will be held during the year and possibly a company publication will be issued to keep the members in close touch with the national work, and a local question box established, supplementing the *Bulletin* of the National Electric Light Association.

First Fall Meeting of the New York Section of the Illuminating Engineering Society.

The first autumn meeting of the New York section of the Illuminating Engineering Society will be held on Thursday evening, October 15, at 8.15 o'clock, in the Engineering Societies Building, 33 West Thirty-ninth street, New York city. A committee, consisting of Dr. A. H. Elliott, Norman Macbeth and E. F. Tweedy, will review the papers and discussions presented at the annual convention. Through the efforts of this committee it is hoped that those members who are unable to attend the convention will receive first-hand information concerning everything of significance and moment which transpires at the convention.

Improvement in Electric Meters.

An attachment for ordinary measuring instruments, as watt-hour or ampere-hour meters, for indicating at any moment the energy or current consumed by a plant, is described by Elpidio Paparella in *L'Elettricista* (Rome) for August 15. The device will operate as a wattmeter when attached to a watt-hour meter, and as an ampere-meter in connection with ampere-hour meters. It is applicable to all motor-meters, in which, as is well known, the velocity of the rotating part is at all times proportional to the power or to the current. In such meters there is always a movable metallic disc which, in the case of direct current, is rotated by a small motor, and in the case of alternating current usually by a rotary magnetic field. In all cases a braking effect is exerted on the rotating part by permanent magnets, which induce eddy currents in the disc, exercising on the same a resisting action rigorously proportional to the velocity. For this reason the magnets themselves are subjected to a pull which tends to drag them along in the direction of rotation of the disc. The invention consists in utilizing this reaction on the magnets for indicating the power in watts or amperes consumed at any given moment by a plant, in which watt-hour or ampere-hour meters are installed. To attain this purpose it is only necessary to make one or more of the brake magnets movable and to counterbalance the displacement effect on the magnet by means of a spring. The tension of this spring suitably indicated by a dial will then show the watts or amperes consumed at any moment. But the permanent magnets are large and heavy, and it would be difficult to construct a sensitive movable system out of them; therefore only a part of the magnetic circuit is made movable—that nearest to the disc; that is, the polar portion of the magnet, where the magnetic effect has its centre. In some alternating-current meters the disc is rotated by electromagnets generating a rotary magnetic field. These electromagnets receive a pull in a direction opposite to the movement of the disc, and in such meters the electromagnets or their polar portions may be used instead of the permanent magnets for measuring instantaneously the watts or amperes consumed, in the manner described. If the hand of the indicator is provided with a pencil bearing on a cylinder moved by clockwork, the instrument may be made into a recording watt or ampere-meter. The device will be economical, as it combines two instruments in one. It may also be used as a substitute for the Wright maximum demand indicator, which only indicates the maximum consumption during a certain time, but not the frequency and duration of any excessive consumption of energy.

Tungsten in the United States.

The demand for tungsten ores and products during the first nine months of 1907 was much greater than that of 1906, prices were high, mining and prospecting were both actively carried on, and as a result the output of the United States was increased from a total of 928 short tons of concentrates carrying sixty per cent of tungsten trioxide in 1906 to 1,640 short tons in 1907, while the value rose from $348,867 in the earlier to $890,048 in the latter year.

The principal tungsten minerals are wolframite, a tungstate of iron and manganese, and scheelite, a tungstate of calcium. Both minerals, like tin ores, occur, as a rule, in quartz veins cutting rocks containing much silica, such as granite and rhyolite, but some apparent exceptions to this rule are found, as, for instance, in New Mexico, where hübnerite and a small amount of scheelite occur with pyrite and lead minerals in a vein cutting limestone; and at Nome, Alaska, where scheelite is found in the gold placers in a region of schists several miles from the nearest granite outcrops. The greater part of the American tungsten product in 1907 came from the mines in Boulder County, Col., which reported an output of 1,146 tons of wolframite valued at $573,642.74. In California, which was the second state in order of production, the output was in the form of scheelite, as was also most of that from Montana. The total scheelite reported was 414 short tons. Small amounts of tungsten ores were also produced in Washington, Nevada, Arizona and probably in New Mexico. No ore is known to have been produced in South Dakota, although much prospecting and some development work was carried on.

In other countries besides the United States the production of tungsten was notably increased during 1907. The output of Australia (including Tasmania), amounting to 1,643 tons, was, however, the only one that exceeded that of this country. Reports of production from South Africa, New South Wales, and the northern territory of Australia, show marked increases. Spain, New Zealand, Austria and Germany, whose combined production during 1906 was 463 short tons, have not made public their figures of production for 1907, but it seems probable that there will be, in each case, an increase.

Concerning the probable future of tungsten, F. L. Hess, of the United States Geological Survey, from whose statistical report for 1907 the foregoing paragraphs have been abstracted, makes the following statement:

"Tungsten deposits are usually pockety; that is, the ores occur in lenticular masses or shoots in veins. Those occurring at the surface are often quickly and easily mined, and it may then require all the profit made from the first-exposed ore body to locate another one. However, the veins carrying tungsten minerals are generally of deep-seated origin, and, generally speaking, other ore bodies will probably be found in depth, although, as in mining for other minerals, the expense of search may be out of proportion to the size of the pay shoots.

"In Queensland the deposits exposed on the surface have been largely exploited and the production has, in the face of rising prices, fallen greatly since 1905. In England, Spain, Portugal, Austria, Germany, Bolivia and the Dutch East Indies tungsten and tin ores occur together, and the working costs are thus lowered. Magnetic separators are increasing the production of tungsten ores in England.

"Tungsten is of widespread occurrence, but the individual deposits can hardly be said to be large. In times of high prices there are many deposits which can be worked that will be idle at lower prices, and, considering the great decrease in value of tungsten ores in the last three months of 1907, it seems probable that the output for 1908 will be much less than in the previous year."

An interesting and important part of Mr. Hess's report is his brief description of the tungsten minerals and some simple tests by which they may be identified. These tests are such as can be made by any prospector who can obtain hydrochloric (muriatic) acid, a test tube, a teacup or a water glass, and a little tinfoil, a piece of zinc, a bit of solder, or even a scrap from an ordinary tin can. Copies of the report, which is published as an advance chapter from "Mineral Resources of the United States, Calendar Year 1907," may be obtained by applying to the Director of the United States Geological Survey, Washington, D. C.

The Paris Metropolitan.

Extensions to the Famous Subway System in the French Capital.

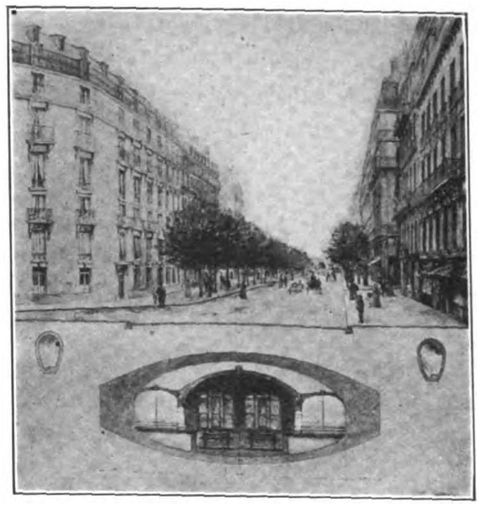
SINCE the system of electric subways was first commenced in Paris not many years ago, it has been greatly favored by the public, and this is seen not only in the figures which show the annual traffic and the receipts of the different lines, but also by the fact that the Metropolitan Company, which controls the subway, has applied to the municipal council at successive periods for an increase in the concessions. These were granted, according to the decisions of a special committee which was appointed for the purpose and known as the Metropolitan Commission. The last of these concessions was granted in December of last year, providing at the same time for the probable construction of five other sections of subway. The number of lines which is covered by these concessions is considerable, and when the whole of the underground construction is finished the city will be covered by a vast network of lines, not less than seventy miles in length, which will reach nearly all the different quarters and will afford exceptional facilities for transportation. Taking into account the transfers which are made at all the points where the lines cross, passengers can pass quickly and comfortably from one part of town to another. The use of the subway affords a decided advantage over the surface cars in that the latter are hardly ever heated during the winter season, while there is always a comfortable temperature in the subway. Again, a passenger is certain to be able to reach his destination in case he is obliged to make a transfer, as the subway cars are scarcely ever filled to the required limit. In France there are only a certain number of passengers carried on a given car or omnibus, and if the latter is full, one is obliged to wait for the next one. At intermediate points during the hours of heavy traffic, especially from six to eight o'clock, all the cars are likely to be full, so that in many cases one may wait indefinitely, and on some of the lines it is practically impossible to make the transfer. Such is not the case with the subway lines, and even during the most crowded periods one can always secure a place after waiting a short time. The cars, it is to be remarked, pass at three-minute intervals, but in the future it is possible that this may be reduced to two minutes.

THE FORM OF CONSTRUCTION IN A NARROW STREET—PARIS METROPOLITAN SUBWAY.

At the present time the work of constructing the different lines of subway is well advanced. As regards the lines which are finished and in actual operation, these are four in number, comprising the east-west section, or original Metropolitan line, the north semi-circular section and the corresponding south semi-circular line, which we have had occasion to illustrate. There has been recently opened a new section which joins on to the south line at the Place d'Italie and then crosses the Seine and runs in a northerly direction, ending at the North Railroad depot. These four lines are entirely finished and represent about twenty-three miles of subway. There are also two new lines which are nearing completion. On one of these, which runs from the Place d'Italie to the Cours de Vincennes, almost all the work is finished but the roadbed and tracks. It includes an overhead part of considerable length. As to the second line, it is entirely in subway and runs from the Avenue de l'Opera to the Place du Danube.

There are two other lines of subway which have a special interest from the work which is carried out in order to run the tunnel under the Seine. The other sections of the Metropolitan are taken across the river upon three bridges lying in different parts of the city, but these are not, however, in the central district. As the use of bridges was not allowed in the central portion of town, the lines were obliged to proceed in subway under the Seine. One of these lines starts in the northern part of the city at the Clignancourt Gate and runs in a southerly direction across town, ending at the Orleans Gate. Where this section of subway crosses under the Seine the tunnel was formed by sinking a series of caissons in the river bed having the standard section of the tunnel. This work has been described in a preceding article[1] and will not be referred to at present, except to say that all the caissons have been sunk in the Seine down to the proper level and this part of the work is well advanced.

Of particular interest at this time is a piece of work which is being carried on at a point somewhat farther down the Seine. This is the crossing point of what is known as the North-South line of subway. It runs across town from the Versailles Gate, in the southern district, to the Place Jules Joffrin, which lies in the northern quarter. It is entirely under ground and in general has adopted the tunnel section which is in use on the other lines. What distinguishes this line from the others from an administrative standpoint is that it lies outside of the regular Metropolitan system, and is operated by another company, which secured the concession from the city several years ago, so that the North-South Subway Company, as it is called, has no financial connection



STANDARD FORM OF CONSTRUCTION ON THE NORTH-SOUTH LINE OF THE PARIS METROPOLITAN SUBWAY.

[1] ELECTRICAL REVIEW, October 12, 1907.

with the Metropolitan system. As the tunnel section and rolling stock are the same as for the above, arrangements have been made so as to effect the transfers from one of these roads to the other at all the crossing points.

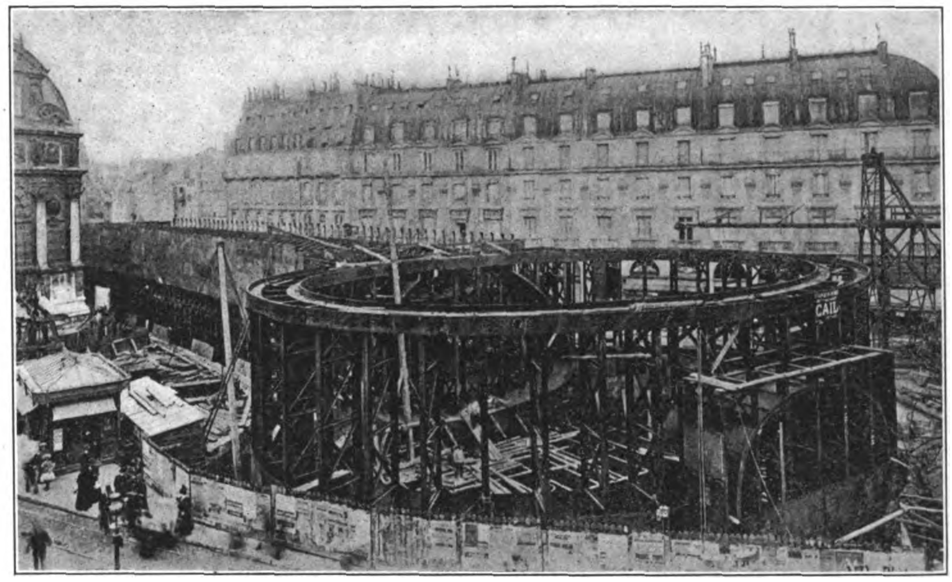
What is to be remarked about the North-South line is the method which is adopted for passing under the Seine. M. Berlier, who was active in the formation of the new company, had the method of compressed-air shield adopted for this work, and the tunnel is accordingly formed of sections of iron rings, which are joined together as the shield advances under the river bed, so as to form a tube which contains one of the tracks, and is about fifteen feet in diameter.

A line of road which has now been entirely completed and is running at the present time is known as Section No. 5. It starts at the Place d'Italie, crosses the Seine and ends at the Northern Railroad depot. At the former point it joins on to the line know as No. 2-South. The No. 2 line and the portion of the No. 5 section lying on the south bank of the Seine form a continuous semi-circular line which is known as the South Semicircle. However, as Section No. 5 not only runs for a long distance on the other side of the Seine, but was also constructed at a later period than the No. 2 line, it is generally considered apart from the latter.

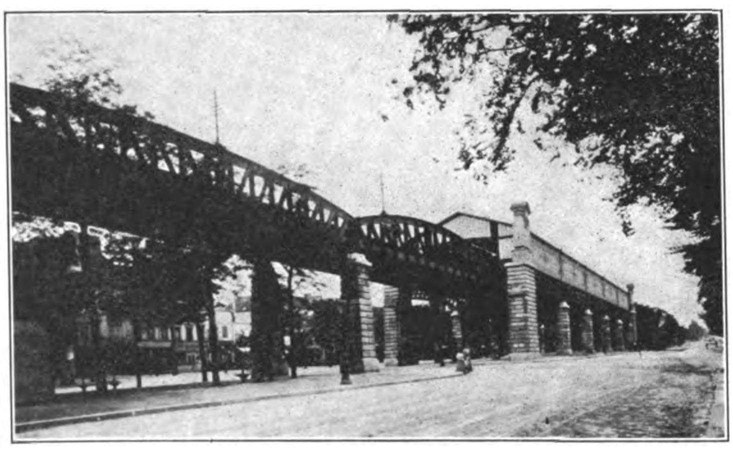
At the North Railroad depot and the East depot, which lie not far from each other, there is quite a complicated series of tunnels and stations in order to provide for the crossing at different levels of the different lines—Nos. 4, 5 and 7. Line No. 5 makes a curve in a semi-circle and passes underneath the station and Line No. 4, and passes in a southerly direction to the Seine. It crosses the river upon an iron bridge which was specially built for the purpose. On the other bank is the Orleans Railroad depot, and it was decided to take the Metropolitan line, which after leaving the bridge is run upon an overhead structure, directly through the building of the depot. This was carried out by making a breach in the walls at the height of the second story, and the tracks are supported here by a single bridge truss, 150 feet long. Passengers descend from the train and reach the ground level of the depot by a staircase.

After passing the depot the line continues overhead, the structure consisting in general of a series of ironwork trusses supported upon masonry pillars or iron columns. Masonry pillars are also used to support the overhead stations. The trusses are usually seventy-five feet long, and the bottom line is seventeen feet above the ground. The total length of the present section is 4.2 miles, and it has fourteen stations, these being either overhead or underground, and about 1,680 feet apart. About $5,000,000 was the outlay for the construction of the present line.

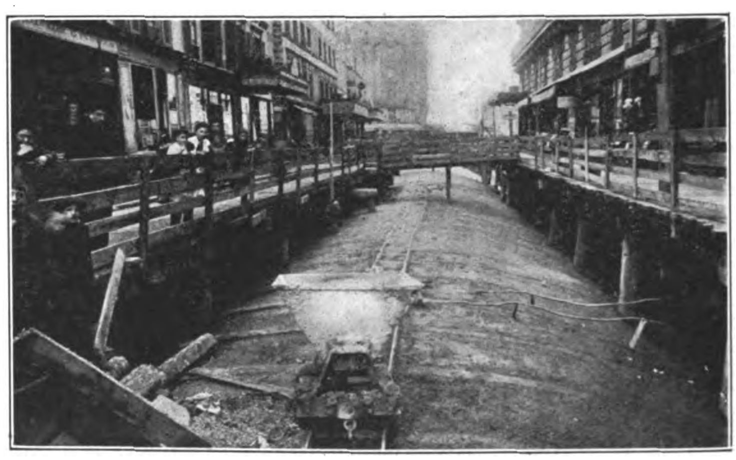
One of the lines (No. 6) which will be the next to be completed is built partly underground and partly overhead. The line runs from the Place d'Italie to the Cours de Vincennes, and crosses the Seine upon a bridge, or rather upon a viaduct which is built on the top of the existing bridge at Bercy in order to accommodate the new line. The beginning of the present section at Place d'Italie forms the continuation of the No. 2 line. Its total length is 3.4 miles of double track and 423 metres of single track at the loops. It begins as an underground line at the Place d'Italie, but comes to the surface shortly after and mounts upon an overhead portion, which it follows until reaching the viaduct upon the Seine. At the opposite bank it passes again in subway



Paris Metropolitan System—The Elliptical Caisson for the Station at Place St. Michel.



Paris Metropolitan System, Showing the Overhead Construction.

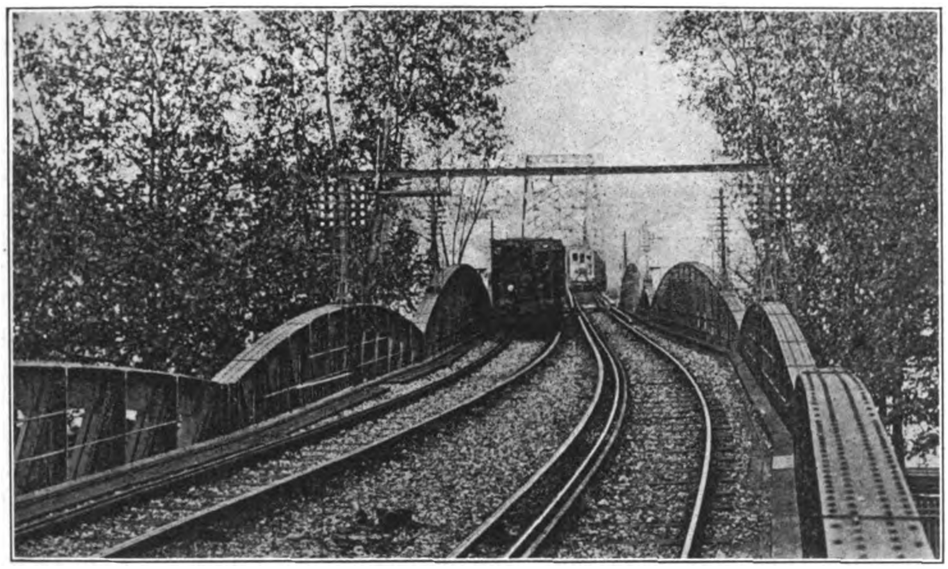


The Paris Metropolitan Subway Showing the Arch of the Roof in Armored Beton.

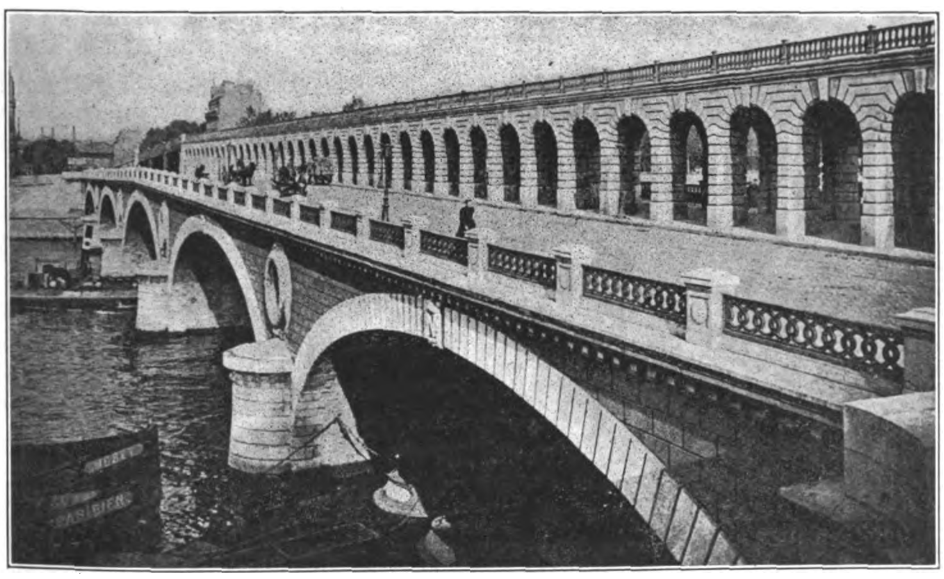
and continues in tunnel as far as the terminus at the Place de la Nation. On the overhead part there are thirty-one bridge truss sections of 22.5 metres average length, and in most cases they are supported upon iron columns. Over the whole line there are ten stations, some of which lie on the overhead portion. The entire construction is finished at the present time, and it only remains to lay the roadbed in order to complete the line.

An interesting series of tables, showing the traffic and income from the system now in operation, has been drawn up by one of the leading engineers of the Metropolitan company, M. Bienvenue. In this way he is able to make some calculations as to what will be the probable amount of traffic over the completed subway system. It is found that the line which runs along near the right bank of the Seine, and known as the No. 1 subway, crossing the city from end to end, showed a traffic for the year 1906 of 42,000,000 passengers carried.

M. Bienvenue estimates that the distance on either side of the subway line within which the population is likely to use this means of communication is 400 metres, or 1,320 feet. Taking the density of the population along this zone and the number of passengers actually carried on any particular line, he is able to establish the relation between the two and so have a very good basis for calculating what will be the probable traffic on any one of the projected lines. The total length of the system is 71.3 miles and the number of passengers which will be carried annually over the whole of the subway is estimated at no less than 395,000,000. This is a large figure, but it is a conservative estimate based upon the above calculations, and indicates the great extent to which the subway will be patronized by the population when it finally covers the different quarters of the city.



Paris Metropolitan System, Showing the Viaduct and Bridge on the Road from Place d'Italie to Lancry.



The Bercy Viaduct over which the Tracks of the Paris Metropolitan System have Been Laid.

A word may also be said as to the receipts from the system of lines which is now in actual operation, comprising 23.6 miles of subway. With a total traffic of 165,000,000 passengers carried during the year 1906, the gross receipts were $5,750,000 in round numbers. The net profit after deducting all expenses is found to be near $1,500,000, which is a very good figure and shows that the affairs of the Metropolitan company are in a flourishing condition. This figures out at $65,000 per mile of subway.

National Association of Cotton Manufacturers.

The semi-annual meeting of the National Association of Cotton Manufacturers was held at Saratoga, N. Y., September 29 and 30. On the afternoon of September 30 the members of the association were the guests of the General Electric Company at Schenectady, N. Y., luncheon being served and an opportunity given to witness the latest developments of the applications of electricity for the transmission of power, illumination and transportation. The ladies of the party did not visit the General Electric works, but were entertained by a committee of Schenectady ladies at the Mohawk Golf Club.

Among the technical papers presented and discussed at this meeting were the following: "Low-Pressure Steam Turbines," by Charles B. Burleigh, Boston, Mass.; "The Textile Mill Power Plant," by Lewis Sanders, New York, and "Measurements of Power and Its Transmission," by William O. Webber, Boston, Mass.

The Textile Exhibitors' Association, which is composed of manufacturers of textile machinery throughout the United States, held its annual meeting in connection with the semi-annual meeting of the National Association of Cotton Manufacturers. The exhibitors authorized the executive committee to prepare for an exhibit of textile machinery in April, 1909, in Boston, Mass. The following officers of the Textile Exhibitors' Association were elected: President, George O. Draper, Hopedale, Mass.; vice-president, F. H. Bishop, Boston, Mass. Executive committee: H. W. Butterworth, Philadelphia; M. H. Merrill, Boston; E. F. Hathaway, Boston, and S. A. Corey, Boston.

Electrical Notes from Great Britain.

(From Our British Correspondent.)

By the time these lines appear in print the electrical exhibition at Manchester, for which manufacturers and the trade generally have been preparing for some time past, will be in full swing, for it opens on October 2 and closes on the 31st of the same month. The executive committee has among its members gentlemen representing all kinds of electrical organizations and interests, including the National Electrical Manufacturers' Association, the Electrical Contractors' Association and the Municipal Electrical Association. Lord Derby is the president and Sir William Preece is among the vice-presidents, the others being the chief municipal representatives of the Manchester and Salford corporations. The Institution of Electrical Engineers has not thought it beneath its dignity to have representatives on the committee. The Lancashire Electric Power Company, which has everything to gain from increased electrical enlightenment among the power-users of Lancashire, is also fully concerned in the scheme. As in the case of the electrical exhibition at Olympia in 1905, the profits, if any, are not to go to private exhibition promoters, but are to be divided between various interests, including charitable organizations and a return to exhibitors. Although the number of exhibitors and the size of their exhibits have been very satisfactory, it is too early to say whether or not exhibitors are likely to get anything like the same percentage return on their "stand" payments as they received when the Olympian results were secured. In the present case there was no suitable building available in Manchester, and so a special one has had to be erected, necessarily at great cost. The management and the executive staff have the benefit of the practical experience obtained at the London Olympia show to guide them in securing success, and to a very large extent history will repeat itself at Manchester so far as semi-popular attractiveness is concerned, but there will be the important difference that the exhibits appealing to the power-user will predominate. Manchester is a city of great manufacturing industries, textile and engineering chiefly, but it is also the centre or heart of a very large industrial area wherein these particular departments of manufacturing, as well as mining works, are pre-eminent, and it is to be expected that every electric light and power supplier within what may be described as the sphere of influence of the exhibition will be benefited by so striking a demonstration of electrical capabilities and applications, as it is bound to awaken interest during the entire month of its run. These various electricity suppliers are co-operating heartily to produce a combined effort, calculated to effectively arouse this interest. Naturally enough, it must follow that if they are rewarded the manufacturer and seller of motors and all electrical material, the electrical contractor who puts in the installations, and indeed the electrical industry of the district, and perhaps of the country generally, must also feel the benefit from this important feature of modern publicity.

The issuance of the notices concerning the annual dinner of the Institution of Electrical Engineers reminds one that the summer and autumn vacation of this body is about to end. Last year the session commenced without a presidential address owing to the illness of Lady Kelvin detaining Lord Kelvin in Scotland. This year, no doubt, we shall get back to the usual method of procedure and have an inaugural address some time in November from the president for the 1908-9 session, W. M. Mordey.

At the autumn meeting of the Iron and Steel Institute, which was held at Middlesbrough from September 28 to October 2, there were several papers read of interest to electrical men. C. H. Merz contributed one on "Electric Power Supply"; C. Koettgen and C. A. Ablett one dealing with "Some Results of Experience with Electrically Driven Rolling Mills"; S. O. Cowper-Coles dealt with "The Production of Finished Iron Sheets and Tubes in One Operation," while among sundry other contributions was one by Professor W. A. Bone relating to "Gas-Producer Practice."

One of the principal subjects under consideration at the annual conference of the Municipal Tramways Association, held at Nottingham from September 23 to 25, was "Some Through-Running Problems and Their Solution," introduced by H. E. Blain, the corporation tramway manager at West Ham. One of the recent important instances of through running involving serious problems was that of the Leeds to Bradford service, where the systems of the two cities are laid to different gauges of track. The introduction of a special truck paved the way for the establishment of a through tramway connection which had been long needed but repeatedly deferred. It is now announced that an agreement has been arrived at between the Leeds and Bradford municipal corporations, which own and operate the systems, for through running, and in view of the current interest in the matter the terms agreed upon may be indicated. Each authority will run an equal number of cars, and the surplus mileage will be paid for by the undertaking in which it is run, on the basis of working expenses. The latter expenses are settled according to a fixed basis which will include the wages of motor men and conductors, the cost of cleaning and oiling cars, cost of uniforms and badges, and maintenance of cars and compensation. The charges will be on the basis of the average cost per car-mile as shown in the last published accounts. Each authority will be entitled to all receipts taken in its own area, but all through fares will be divided equally up to an agreed number; above this number the division will be in the ratio of the route-mileage traversed on each system, approximately five and one-half miles for Leeds and four miles for Bradford. The general managers will control the traffic arrangements of the respective areas, and employés will abide by the regulations in force in the district in which they are working. If there are any matters in dispute between the two municipalities at the end of the first year's working, these are to be referred to an arbitrator who has the approval of both parties or to the board of trade.

Among the other items in the programme of the Nottingham convention were: A presidential address by J. Aldworth, the Nottingham Corporation tramway manager, and a couple of papers on ticket check and the treatment of incapable tramway employés.

Some years ago much interest was evoked in trackless trolley systems as a result of experimental work of the kind that had taken place in Italy and other Continental countries. A paper on the whole subject was read before the Bradford meeting of the British Association by J. G. W. Aldridge, and there were proposals put before Parliament which aroused hopes of such a system of cars being run to serve some routes in, we believe, a Gloucestershire district. For some reason or other nothing was done, and so far as actual work was concerned the system was practically forgotten. Interest has now, however, been revived, and the prospect of something being done is far more hopeful than it was seven or eight years ago. Several municipal corporations have recently sent deputations to the Continent to investigate as to what the experience accumulated there has to say to them as a guide, and they have returned very favorably impressed with the suitability of trackless trolley cars for use in some of their outlying districts where at present the traffic is insufficient to justify big expenditure upon tramway-track work. The deputation from Manchester, after an investigation of the system in Germany, is recommending its trial on one of the suburban roads not yet served by tramways. It is stated that whereas the working expenses on Manchester trolley tramways amounted to 7.07 pence per car-mile last year, the figure for a trackless trolley line would be only 5.38 pence per car-mile, showing a substantial saving, but, needless to say, the figures are estimates and therefore are received with much reserve. Manchester has experimented with omnibuses of the petrol type, and expressed its disgust by ordering their removal from the streets. This happened some time ago. It has now resolved to permit another trial for three months with steam 'buses. Dublin also has a trackless trolley scheme under consideration, the route suggested being from Donnybrook to the seaside resort, Bray. F. Douglas Fox, who is associated with the concern which is endeavoring to introduce the trackless trolley system in England, read a lengthy paper on "General Urban and Interurban Transportation and Railless Traction" before the Dublin meeting of the British Association in September. After producing statistics of the working costs, etc., of a number of English electric tramways, he proceeded to show the economy anticipated with railless systems. He stated that by this method electricity had entered the field of highway transportation with much more likelihood of favorable competition with both the tramway and the light railway.

The railway department of the board of trade has just issued its report on the fire that occurred last July on the City & South London Electric Railway, near Moorgate Street station. It appears that though the fire was not completely extinguished, other trains were allowed to pass, creating a draft which needlessly prolonged it. The origin of the fire is uncertain. The evidence of the electrical engineer pointed to leakage of current sometimes occurring between the power rail and the running rail through iron and carbon dust accumulating on the sleepers and insulators, this dust and the upper surface of the sleepers catching fire. The board of trade report says that this may have been the cause, or possibly sparks from the locomotive shoes ignited the dust. The reporters refer to the extremely dirty state of the tunnels, some of the dirt being dangerous; oil dripping takes place in some parts and pieces of waste have been found on fire. The smoke danger in such tubes, however, is believed to be worse than the actual fire danger, and the recommendations which the reporters make for preventing these troubles as far as possible are as follow:

1. Considerably greater attention should be given to cleanliness; dust should be more carefully removed.
2. A liberal use of whitewash would enable any accumulation of dust to be detected.
3. The filling up of the inverts, particularly of the large tunnels, should be carried out.
4. No electric wires or cables should be carried below or between the sleepers, but they should be neatly arranged along the sides of the tunnels, and all crossing of cables should be overhead.
5. The use of wood should be eliminated as far as possible; the planking and the wooden platforms should be replaced by slate or granolithic slabs.
6. On discovery of a fire, all traffic should be stopped in that section until the fire is completely extinguished.
7. Prompt notice should be given to the fire brigade.

The Metropolitan and District Railway companies are introducing further improvements in their electric train services. During the hours of heaviest traffic the main-line service between Gloucester Road and the Mansion House stations will be increased from thirty to thirty-four trains per hour; at lighter times twenty-six instead of only twenty-two trains per hour will be run. Some of the three and five-car trains will have an additional car at busy times, and more express trains between the city and suburbs will be introduced; the nine-car train, claimed as the record multiple-unit train of the world, is to be lengthened by a further car, making its length 500 feet, and a second like train is also to be run.

An exhibition which is receiving a good deal of attention at the present time is the International Rubber Exhibition, opened at Olympia on September 14. Specimens of rubber in the rough and in all stages of manufacture are on view, having come from all the rubber-producing countries of the world. Interesting exhibits there are of various classes of machinery employed in the manifold operations necessary in dealing with the rubber itself and in manufacturing rubber articles.

Some discussion is taking place just now concerning the discharge of a number of employés of the National Telephone Company, the figure being put at 1,000 for the whole of the United Kingdom. It will be remembered that the company's undertaking is to be taken over by the government in the year 1911 upon terms which were agreed upon between the parties after prolonged negotiations several years ago. The reason given by Mr. Franklin, the company's chairman, for the dismissals is that in the closing years of the company's business (there are only three years to run) there must be "some limitation of expenditure" of "capital which would not be productive within the period of the license," and for which only a depreciated value might be paid by the government. What the company wants is a definite understanding with the government that any money it spends on behalf of the period subsequent to 1911 shall be recouped to it without loss. Every one will hope that in the interests of the extension of the telephone service of the kingdom some such understanding will be speedily arrived at.

It is announced that Robert Nelson, of the well-known firm of Merz & McLellan, consulting engineers, has been appointed by the government to be his majesty's electrical inspector of mines. The office is an entirely new one.

On September 18, at the Hotel Cecil, London, a demonstration was given of Hans Knudsen's apparatus for the wireless operation of a linotype keyboard from a distance, and for the transmission of photographs. A. H. BRIDGE.

London, September 26, 1908.

Electrical Notes from Europe.

(By Our Special Correspondent.)

FOR some time past the French Government has been taking an interest in the matter of wireless telephony, especially from a military standpoint, and three officers of the navy, Lieutenants Jeance and Colin and Engineer Mercier, have been engaged with a system of wireless telephone apparatus at the Eiffel Tower, in Paris, which, it will be remembered, is under the control of the War Department. This apparatus is not, as has been stated, of a sensational character, but follows the general lines of the existing wireless telephone instruments. It was desired in the first place to find a type of apparatus which was adapted to be used for signaling between war vessels or from the latter to coast stations, and M. Thomson, the Minister of Marine, is having the present work carried out by engineers at the tower plant who were appointed for the purpose. From the start of the tests, which occurred only recently, the success of the new apparatus was assured, as on the first trial at long distance it was found that they could reach the post at Dieppe, which contained a like set of instruments. The distance is nearly 100 miles, and conversation could be heard during the day and night. As the weather was stormy at the time there is no doubt that greater distances can be covered. At present the record of distance was made by M. Poulsen, the inventor of the system, who states that he was able to telephone from a point near Copenhagen as far as Berlin, at a distance of 234 miles.

While upon the present subject we should not neglect to mention the preparations which are being made at the Eiffel Tower station for receiving wireless telegraph messages from America. The first experiments will be carried out during the night, so as to avoid the disturbing effects which occur during the day. The apparatus at the tower plant is now in readiness to begin the experiments with New York, and these will be carried out very shortly. However, when the new high-power plant of the tower station is finished much greater distances can, no doubt, be covered. Work has now been commenced upon the underground station which is to replace the present plant. Its operations were much hampered owing to the small power of the apparatus, and the change will bring about quite a new state of affairs.

An enterprise of an interesting nature has been undertaken by the company which operates the Solingen mines in Westphalia. It is taking steps to utilize the peat bogs of this region, and will burn the peat in an electric plant which is to be erected on the spot. Current will be sent from the station in order to supply the towns and villages of the district. At the same time the peat will be used to furnish various chemical products by treating it in the proper way. It is found that sulphate of ammonia can be produced to advantage by this method, and the company has already been working a chemical plant with some success. It is proposed to utilize the vast peat bogs which lie in the Rhine region in the district of Westphalia and Hanover, and current will be produced much more cheaply than from coal.

The new Edison battery is used on an automobile car which has been recently put in service in Berlin. It is constructed by the Bergmann firm and uses a five-horse-power motor with a gear ratio of 5 to 1, working upon the rear axle of the car. There are sixty-four cells of the Edison battery used, and these furnish eighty volts for the motor, which works at a speed of 1,500 revolutions per minute. The battery is held in eight different wood cases. Each of the cells weighs sixteen pounds and gives 1.23 volts. The entire battery furnishes fourteen kilowatt-hours, and the charging current is sixty-five amperes at three and one-half hours' duration. The motor has two separate windings and the battery is divided in halves. By varying these different circuits at the controller the various speeds of the car are obtained, of which the highest is twenty miles an hour. The expenditure of energy is found to be seventy-five watt-hours per ton-kilometre. With battery and motor, the car weighs 16.5 tons.

A new process for making an insulator which is said to resemble ebonite has appeared on the Continent. Powdered tan bark is mixed with one-third of sulphur and the whole is heated until the sulphur melts, when the mixture is well stirred and then cooled. It has the form of small, black grains. These are put in a pressure mold and heated from the outside; this gives a block or a piece of insulating material of any form. The new insulator is said to possess many of the properties of ebonite.

Owing to the successful operation of the Ronchamps central station, which distributes current in the Belfort, Vosges and other regions in the eastern part of France, it has been decided to add a new steam turbine to the three existing units. This will be a turbine-alternator group of 5,000 horse-power, and it will use a transformer for giving 30,000 volts upon the power line.

Owing to the disastrous fire which occurred at the central telephone exchange of Paris, the principal subscribers in the business district will be obliged to do without the telephone for two months or more. There are nearly 20,000 subscribers affected by the loss of the exchange. The fire broke out about seven o'clock on the evening of September 20, when the odor of burned rubber appeared in the fifth or top floor of the building, where the new multiple switchboard on the central-battery system had been installed. An inspection of the apparatus showed that the ground cables placed in the basement were no longer in working order and that there must have been a short-circuit at that point. The cables which come from all over the centre of the city run into the basement and are thence brought through the building. The employés were ordered to leave the building as a fire was commencing to break out, no doubt in the basement, and owing to the inner conduits and shafts for the cables, the fire soon commenced to gain all the different stories of the building, which is a five-story one. The Gutenberg exchange fronts on the Rue du Louvre and extends back for a considerable distance to the Rue Jean Jacques Rousseau, being a long and narrow building, lying against the dwelling houses on one side and separated by the Rue Gutenberg, a narrow passage, from the Central Post-Office building.

Shortly after the employés had left the fire was seen in the top story, and it seemed to have reached this point directly from the basement by the shafts above mentioned. Soon afterward the fire spread to the floor underneath. The firemen, who soon arrived, could not enter the basement as the fire was in full progress there. At nine o'clock the whole building formed an immense brazier from which escaped flames and calcined stone. The metallic structure of the building, however, remained solid. Owing to the efforts of the firemen and the great number of hose which were made to play on the flames, the fire was gradually brought under control, and was finally put out several hours after. Two companies of infantry were brought out and they aided in keeping order around the building.

But little, if any, of the material which occupied the exchange can be saved, and most of the multiple telephone boards are a total wreck. In four stories of the exchange were installed the multiple switchboards, which served for 20,000 subscribers, or very nearly that number. There were also the boards for the suburban and interurban service. This latter suffered the least, but as regards the rest of the apparatus it is totally lost and the subscribers in the business part of Paris will be obliged to have recourse to the public cabins in order to use the telephone, and this state of affairs will last until a temporary exchange can be erected. A great disturbance among users of the telephone was thus occasioned. It was of the first importance to establish communication between Paris and London, Berlin and other cities, which had been cut off. This was done within twenty-four hours, and the ministerial offices, War, Navy and others, were also cared for, as it was most important that the government administrations should not be deprived of the telephone. The Bourse suffered greatly from the lack of communication, and it became difficult to carry on certain kinds of commercial affairs where the stocks fluctuate rapidly.

Usually there are 1,400 female telephone employés in the Gutenberg exchange, but as the fire occurred on Sunday, the number was much less, which was fortunate. No one was hurt on this occasion and the firemen, although they suffered much from the intense heat, were not injured. It is therefore a matter of congratulation that no lives were lost. The minister of Public Works and the Postal Telegraph and Telephone secretary are taking measures to restore order within the least possible time. The interurban service suffered the least, and it will be transferred to the other telephone exchanges of the city. A part of the apparatus will be installed in the office near the Bourse and the Chamber of Commerce will be asked to afford other localities in the central part of town. After establishing the London and Brussels telephone lines, the next in order will be the Bordeaux line, then the Lyons and other home telephone lines. Among the foreign lines, those to be opened first will be the Berlin and Frankfort lines.

Besides the damage to the telephone service, the telegraph also suffered from the fire. A certain number of telegraph cables pass in the basement of the Gutenberg exchange, especially the English and Belgian cables. About 800 feet of cable were destroyed in the basement. After the disaster there were four telegraph lines established with London and two with Brussels. By the time the present account appears the foreign and interurban lines will have all been established both for the telegraph and the telephone, as the work is being pushed forward with all haste.

The city subscribers will suffer most, however. It will take at least two months before a temporary exchange can be erected and there seems no other way of solving the problem. However, all the public cabins will be in working order, as they will be at once connected with the other exchanges of the city. At the same time there will be many temporary cabins opened up either in the post-offices or in other localities, and the subscribers will have the free use of these by showing their card. This, however, will be but a feeble remedy for the difficulty, and most of the business offices will suffer considerably. This applies to the 20,000 subscribers who were connected to the Gutenberg exchange. The rest of the subscribers in the city, to the number of 25,000, are using the telephone as usual, seeing that they are connected to the six outer telephone exchanges which are of smaller size. But they can not, of course, communicate with the central subscribers' lines and will thus be cut off from the central part of town. This will mean a great rush at the public telephone cabins in all parts of the city. No doubt the use of pneumatic cards and telephonic messages will increase. In the latter case one may telephone from a cabin to the employé in another office, who writes down the message and it is delivered to the desired address. Outside of the direct use of the telephone this is the quickest way to communicate from one part of town to another.

It is proposed to erect the provisory exchange, or rather two separate buildings, each with 10,000 subscribers, in the space which is embraced by the Louvre building, known as the Carrousel Place. This will be very objectionable, as it will spoil the appearance of this attractive site, but as it is necessary no doubt the measure will be approved. Two months at the very least will be needed to fit up this exchange, and the 20,000 subscribers will then be satisfied. Meanwhile there will be measures taken for the building of a new exchange, probably on the site of the present one, but this is not certain. At least, the use of a smaller unit for the exchanges is found necessary, as had such been the case the fire would not have caused the same damage. As to the monetary loss, this is difficult to judge at present, but the Paris journals mention sums varying from six to eight million dollars.

C. L. DURAND.

Paris, September 26.

The Old Time Telegraphers' and Historical Association.

The twenty-seventh annual reunion of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps was held at Niagara Falls, N. Y., September 16, 17 and 18. Headquarters were established at the Cataract International Hotel. There were in attendance a large number of delegates and guests, and the meeting was successful in every way.

The business meeting of the Society of the United States Military Telegraph Corps was held on the morning of Wednesday, September 16, Colonel William B. Wilson, the president, occupying the chair. The reports of the president, secretary and treasurer were presented, and the constitution and by-laws with all amendments made since 1882 were re-adopted.

J. H. Robinson, of Washington, D. C., addressed the meeting, referring particularly to the deeds of heroism performed by the military telegraphers during the Civil War.

It was resolved that all persons eligible to membership may be elected to life membership by the payment of $50, in which case the payment of annual dues will not be required.

A resolution was also adopted recording the appreciation of the society of the provision made by Andrew Carnegie for meeting the wants of the aged and needy members of the corps.

A resolution was passed expressing the appreciation of the society of the services to the organization of James E. Pettit, its secretary and treasurer for twenty-six years.

The following officers were elected: President, William B. Wilson, Philadelphia; secretary and treasurer, David Homer Bates, New York; vice-presidents, William L. Ives, New York, and Charles A. Tinker, Brooklyn.

General Thomas T. Eckert and Colonel Robert C. Clowry were elected honorary members of the society.

The business meeting of the Old Time Telegraphers' and Historical Association was held at 2 o'clock on Wednesday afternoon, September 16. The meeting was called to order by Harvey D. Reynolds, president, and Franklin D. McKenna, corporation counsel of the city of Niagara Falls, welcomed the delegates and members to the city in behalf of the mayor. The reply for the association was made by William J. Dealy, of New York.

In his presidential address Mr. Reynolds referred to the death of former President William Hamilton Young and of Secretary John Brant.

M. J. O'Leary, of New York, who was appointed to act as secretary *pro tem.*, read the report of the secretary and treasurer.

The following officers were elected: President, E. B. Saylor, Pittsburg, Pa.; first vice-president, C. E. Bagley, Pittsburg, Pa.; second vice-president, W. J. Camp, Montreal, Canada; secretary, Frank J. Scherrer, New York.

Northwest Electric Light and Power Association.

About seventy-five representatives of electric light and power companies in Washington, Oregon, Idaho and Alaska have organized the Northwest Electric Light and Power Association. A meeting was held in Seattle, Wash., on September 19, to bring together these interests, and the session closed with a banquet on the evening of that day.

The following officers were elected: President, Arthur Gunn, Wenatchee, Wash.; first vice-president, A. Welch, Portland, Ore.; second vice-president, Francis Rotch, Fairbanks, Ore.; third vice-president, Henry Adams, Lewiston, Ida.; temporary secretary, J. D. Crary, Aberdeen, Wash. Executive committee: H. L. Bleeker, Portland, Ore.; I. W. Anderson, Walla Walla, Wash.; E. E. Potter, Seattle, Wash.; L. B. Faulkner, Olympia, Wash.; C. G. Arrowsmith, North Yakima, Wash.; O. B. Caldwell, Portland, Ore., and N. J. Shields, Moscow, Ida.

Electrical Transmission of Time Signals Without Wires.

A system for the distribution of time signals by means of Hertzian waves, invented by Franz Morawetz, of Vienna, is described in *L'Industrie Electrique*. Paris, September 10, by Dr. A. Ferla. Attempts in this direction had already been made, but have failed on account of disturbances caused by extraneous, such as atmospheric, electric waves. The inventor conceived the idea of constructing an apparatus which remains in circuit only during one second. As soon as an electric wave strikes it, it is disconnected from the circuit by a suitable clockwork and remains in this condition for fifty-nine seconds. Thus the apparatus is capable of receiving a signal only during one second out of sixty and can be actuated only once in a minute, either by a wave intended for this purpose, or by some other wave. Mr. Morawetz, in conjunction with Professor Reithoffer, of the Vienna Technical High School, investigated the behavior of electric waves in a large city and the construction of apparatus for their utilization. A central station was installed in 1905 on the roof of the Technical Institute in Vienna, for which the municipal council granted a subsidy of 3,000 francs, and the best form of antennæ and the most favorable wave length were studied. The experiments showed that a wave length of 765 metres had the necessary inflection to overcome the inequalities of the territory. In 1906 the influence of atmospheric electricity on the apparatus was investigated and observations were made simultaneously at two receiving stations, one at Breitensee and the other at the Siemens-Schuckert works on the Praterquai. An increase in atmospheric electricity often manifested itself hours before the formation of clouds indicating a thunder storm. An extraordinarily violent thunder storm, which struck Vienna in July, 1907, did not disturb the system in the least and proved its complete insensibility to atmospheric electricity. Although the discharges succeeded one another almost without interruption, the clocks continued to keep exact time. The waves sent out from the central station could be distinguished very clearly from the atmospheric sparks at the coherer by their color. During the trials it was likewise demonstrated that large masses of metal are no obstacle to the propagation of electric waves. The metallic cupola of the St. Charles Church is between the central and one of the receiving stations, but with the wave-length employed the signals arrived without being disturbed or weakened in the slightest. During the experiments the sending and receiving instruments were perfected. At the central station the high-tension wave-transmitting apparatus is actuated by an electric clock invented by Mr. Morawetz. This clock is capable of closing the circuit of a transformer during a time-interval of either one, two, three or four seconds and from one to three times per minute. The secondary circuit of the transformer charges a battery of 100 Leyden jars, which is discharged across a spark-gap, producing radiating electrical oscillations in the antennæ. As the radiations can not be produced on one side of the circuit only, the other terminal is connected to the ground. At the receiving station in Breitensee a steel tube pole, twenty metres high, is installed in a wooden socket. The antennæ consist of copper wires suspended from an insulated cross-bar at an angle of forty-five degrees. The wires are joined at the bottom, enter the station through a glass tube and are likewise connected to the ground. When the waves reach the receiving antennæ, which must be in resonance with the oscillations, a system of induction coils and condensers transmits them to the coherer, and the latter closes a local circuit by means of a very sensitive relay. The chronometric apparatus of Mr. Morawetz, the principal part of the invention, consists essentially of a clock movement which, when actuated by the waves, interrupts communication with the receiving devices, so that signals can be received only during a predetermined number of seconds. If any extraneous wave arrives at another time it operates the apparatus at the receiving station, but the wave from the central station remains ineffective. In such a case there will be a slight discrepancy between the central and receiving stations, which will, however, be compensated during the following minute and can not exceed a few fractions of a second. The secondary clocks at the receiving stations may, of course, be of any construction. The advantages of this system are that the operation of the central station can be effected by a single master clock, that the installation of a great number of circuits is rendered unnecessary, and that the system may be extended without limit over a whole city, and eventually, by increasing the power at the transmitting station, over a whole country, without danger of disturbance. The cost of such an installation of clocks will be very nearly equal to that of a corresponding number of mechanical clocks, and it may be concluded that they will be the clocks of the future.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

SOUTH SIDE ELEVATED.

The income of the South Side Elevated Railway Company, Chicago, Ill., for the year ended June 30, 1908, as filed with the Warehouse Commission is as follows: Gross, $2,242,345; expenses, $1,569,231; net, $673,114; charges, rents, etc., $377,-684; surplus, $295,430; depreciation, $50,000; balance, $245,430; dividends, $281,317; deficit, $35,887, comparing with a surplus of $69,107 for the previous year.

METROPOLITAN WEST SIDE ELEVATED.

The Metropolitan West Side Elevated Railway Company, Chicago, Ill., reports as follows for the year ended June 30, 1908: Gross, $2,809,483; expenses, $1,457,152; net, $1,352,341; other income, $5,016; total income, $1,357,357; charges, $1,070,780; surplus, $286,577; dividends, $65,320; surplus, $221,257, which compares with $195,858 for the previous year. During the year the Metropolitan company paid off $376,387 equipment notes and purchased and paid for $200,000 new equipment. The total expenditure for equipment was $576,387. During the year the company increased its funded debt $400,000 by the sale of extension bonds. The difference between this sum and cost of equipment, or $176,387, was taken out of surplus. The company also reduced its collateral loan $50,000.

MINNEAPOLIS GENERAL ELECTRIC COMPANY.

The Minneapolis (Minn.) General Electric Company's gross earnings show an increase of $9,996 for July. This was offset to some extent by an increase of $1,662 in expenses. The July gain in net earnings was $4,374. For the twelve months the gross earnings showed a gain of $81,666, and the expenses were cut $3,027. The increase in net earnings amounted to $84,692 for twelve months. In detail the report for July is as follows: Gross earnings, $73,889, increase, $9,996; expenses, $32,025, increase, $1,662; net earnings, $41,864, increase, $4,374; charges and taxes, $32,400, increase, $5,576; July surplus, $9,464, decrease, $1,202. For twelve months: Gross earnings, $961,506, increase, $81,666; expenses, $435,638, decrease, $3,027; net earnings, $525,868, increase, $84,692; charges, $354,422, increase, $132,764; surplus, $171,446, decrease, $48,672.

DETROIT UNITED RAILWAY COMPANY.

The report of the Detroit United Railway Company for the month of August and eight months ended August 31, 1908, is as follows: August gross, $691,489; expenses, $443,939; August net, $247,550; other income, $4,957; total income, $252,-507; charges, $134,859; August surplus, $117,648, comparing with $171,168 for August, 1907. Eight months' gross, $4,656,365; expenses, $2,972,116; eight months' net, $1,684,249; other income, $40,028; total income, $1,724,277; charges, $1,083,811; eight months' surplus, $640,466. This compares with $773,763 for the corresponding months of 1907, a decrease of $133,297.

LEXINGTON & INTERURBAN RAILWAYS COMPANY.

The report of the Lexington & Interurban Railways Company for the month of August and eight months ended August 31 is as follows: August gross, $63,246; expenses, $35,844; August net, $27,402. Eight months' gross, $402,540; expenses, $260,593; eight months' net, $141,947. This is an increase of $15,547 over the corresponding figure for 1907.

MEMPHIS STREET RAILWAY.

The Memphis (Tenn.) Street Railway Company's report of earnings for the month of August and eight months ended August 31 is as follows: August gross, $141,191; expenses and taxes, $87,929; August net, $53,262; charges, $35,532; balance, $17,730; reserve funds, $2,500; August surplus, $15,230, comparing with $21,786 for August, 1907. Eight months' gross, $1,056, 720; expenses and taxes, $671,347; eight months' net, $385,373; charges, $279,437; balance, $105,935; reserve fund, $20,000; eight months' surplus, $85,935, comparing with $115,733 for the corresponding period of last year.

NASHVILLE RAILWAY AND LIGHT.

The Nashville (Tenn.) Railway and Light Company reports earnings for the month of August and eight months ended August 31 as follows: August gross, $127,795; expenses and taxes, $78,-166; August net, $49,629; interest charges $32,811; balance, $16,818; reserve funds, $3,829; August surplus, $12,988, as against $16,983 for August, 1907. Eight months' gross, $1,015,782; expenses and taxes, $620,565; eight months' net, $395,217; interest charges, $253,975; balance, $141,243; reserve funds, $30,357; eight months' surplus, $110,886, comparing with $140,615 for the previous year.

LITTLE ROCK RAILWAY AND ELECTRIC.

Little Rock (Ark.) Railway and Electric's earnings for the month of August and eight months ended August 31 are as follows: August gross, $56,868; expenses and taxes, $28,851; August net, $28,017; charges and sinking fund, $11,-315; balance, $16,701; reserve funds, $3,000; August surplus, $13,701, comparing with $18,968 for August, 1907. Eight months' gross, $441,161; expenses and taxes, $227,568; eight months' net, $213,593; charges and sinking fund, $80,190; balance, $133,402; reserve funds, $24,000; eight months' surplus, $109,402, as against $126,159 for 1907.

NORFOLK & PORTSMOUTH TRACTION.

The Norfolk & Portsmouth (Va.) Traction Company's earnings for the month of August and eight months ended August 31, are as follows: August gross, $174,872; expenses, $94,575; August net, $80,297. Eight months' gross, $1,232,-295; expenses, $740,436; eight months' net, $491,859, comparing with $642,039 for the corresponding months of 1907. The large net earnings for 1907 are due to the Jamestown Exposition.

Comparative Operating Costs of Small Arc Lamps and High Candle-Power Osram Lamps.

Hermann Remane makes a comparison in the *Elecktrotechnische Zeitschrift*, August 20, between high-candle-power osram lamps and small arc lamps. The osram lamps are made of 200, 300, 400 Hefner candle-power and 110 to 130 volts, and from 200 to 250 volts, consuming one to 1.1 watt per horizontal Hefner candle. Tests made with direct current and alternating current show a useful life of 800 hours, during which time the candle-power decreased from five to six per cent. The mean spherical candle-power is given as seventy-nine per cent of the mean horizontal, which is the same figure found by the Reichsanstalt for osram lamps up to fifty candle-power. It is stated that the osram lamp is of greater efficiency than the open direct-current arc lamp of less than five amperes and alternating arc lamps with pure carbons of less than fifteen amperes. Comparison is also made of the operating costs of arc lamps and osram, and it is found that the osram lamp is commercially much superior to the direct-current open arc of less than six amperes, and enclosed arcs up to 6.5 amperes, and to the alternating open arc of any size up to twenty amperes.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Electric Automobiles.

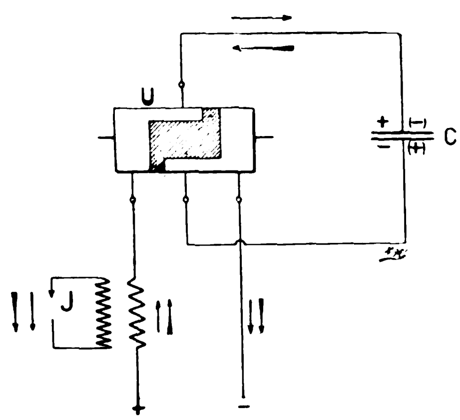
An electrically operated automobile, built by the Siemens-Schuckert Company, known as type "B," is made in three parts, the chassis, the storage battery and the body. The framework is of pressed Siemens-Martin steel. The front part carries an auxiliary frame of the same steel and serves as a base for the storage battery. The motor is suspended in a ring in the middle of the body, and drives the rear wheels through the medium of a differential gear. The normal capacity of the motor is 4.2 horse-power. The storage battery consists of forty-four cells, having a capacity of 145 ampere-hours at a five-hour discharge rate. For charging ninety-five to 120 volts are necessary. It is claimed that the advantage of an electrically operated automobile is safety in operation, doing away with noise and obnoxious odors common to gasolene and other explosion motors.—*Translated and abstracted from Centralblatt für Accumulatoren und Galvanotechnik, August 20.*

Series Repulsion Motor of Alexanderson.

Rudolf Richter starts out with a reference to a paper read before the American Institute of Electrical Engineers at Niagara Falls on the "Choice of Frequencies for Single-Phase Traction," fifteen or twenty-five cycles, which seemed to favor fifteen cycles, until Steinmetz pointed out the fact that Alexanderson succeeded in building a single-phase railway motor for twenty-five cycles having the same efficiency as the fifteen-cycle motor. It was pointed out that the weight of the twenty-five-cycle motor is about the same as that of the fifteen-cycle machine, and that the Alexanderson twenty-five-cycle motor is to be preferred. The author also discusses Alexanderson's paper on "Single-Phase Railway Motors." The article runs through two issues and contains many interesting charts and diagrams, giving comparisons between the Alexanderson and other commercial types of single-phase motors. The author also discusses the spark voltage of the different types at different loads.—*Translated and abstracted from Elektrotechnische Zeitschrift, August 20 and 27.*

The "Grissonator."

The name "Grissonator" has been given to a converter constructed by the firm of Grisson, in Berlin, for transforming direct current into interrupted current or into alternating current of any tension. The transformation is not effected by a circuit interrupter, but by the direct charge and discharge of a condenser. The direct current to be transformed flows from the positive pole of the source in the direction of the unfeathered arrow through the primary of an induction coil J, passes through the commutator U composed of small brushes and two collector rings, through the condenser C, and thence to the negative pole. The current charges



THE "GRISSONATOR."

the condenser to the tension of the direct-current source. At the end of the charge the current ceases of itself and, if the circuit is broken, this does not produce an interruption of the current, but a simple opening of the circuit without current. When the commutator U is rotated by a small motor the small brushes pass without current over the insulating part of the commutator, while the condenser maintains the tension of the current source. If the commutator continues to rotate a contact is made between the condenser and the opposite pole of the current source, and consequently a new charge flows in the same direction through the induction coil and charges the condenser in the direction of the feathered arrow. This apparatus is particularly useful with Roentgen-ray installations, for the secondary effect is not brought about by the extra current caused by the making and breaking of the circuit, but exclusively by a series of current impulses resulting from the closing of the circuit. The condenser used with this apparatus consists of aluminum sheets immersed in a special electrolyte, which become covered with a skin formed by disengaged oxygen when the apparatus is in operation. A condenser of this kind measuring twenty-five by twenty-five by thirty centimetres has a capacity of over 500 microfarads. The aluminum forms the anode and the electrolyte the cathode.—*Translated and abstracted from L'Electricien (Paris), September 5.*

Electrometallurgy at the Marseilles Exposition.

The employment of high temperatures was only made possible after the discovery of the electric furnace, and since its application to the production of aluminum great progress has been made in the manufacture of numerous siderurgical products, a great variety of which is to be seen at the Marseilles exposition, says M. de Kermond. The oldest firm engaged in the electrometallurgical industry in France is the Société Electrométallurgique de Froges, which originally started with a few hundred horse-power, about ten years ago, but now utilizes about 30,000 horse-power. The manufacture of aluminum by the Héroult process has been its principal occupation. It exhibits aluminum in ingots, sheets, bars, wires, cables, tubes, etc., and a magnificent collection of kitchen utensils. The use of this metal in the transmission of electrical energy, one of its important applications, is illustrated by exhibits of wires, cables, binding-posts, splices, etc. The firm of Morel exhibits aluminum rivets and tubes for special purposes, as oil and nitric acid channels, refrigerating apparatus, sign letters, medals, keys, etc. The cooking utensils exhibited are recommended not only for their beautiful appearance, but also for their indefinite wearing qualities. The Société Electrométallurgique has also installed an extensive plant for the electrical manufacture of steel and has put out products which are equal, if not superior, to the best brands of crucible steel. Among the samples exhibited there may be mentioned: Extra soft steel containing only traces of carbon; steel with very high carbon contents, up to 4.06 per cent; steel containing phosphor up to one per cent, sulphur up to 1.5 per cent, and silicium, manganese, chrome or tungsten in desirable quantities. By means of the Héroult electric furnace it is also easily possible to produce quick-cutting chrome, tungsten, vanadium and molybdenum steels. Photographs are exhibited of the oscillating Héroult electric furnace, in which these interesting products are manufactured. So far these fine steels made in the electric furnace have been used only for tools, but the time is coming when they will be cheap enough to be employed for all purposes. The same company manufactures also iron alloys, which are now so much appreciated in the siderurgical industries, and has exhibited samples of chrome iron containing from one to two per cent of carbon and from fifty to seventy per cent of chrome; silicium iron containing from twenty-five to fifty per cent of silicium; nickel iron containing about forty per cent of nickel, two per cent of carbon and less than two per cent of silicium. Samples of the raw material, bauxite, from which aluminum is made, complete this interesting exhibit. —*Translated and abstracted from L'Electricien (Paris), September 5.*

The Frequency of Telephone Currents.

This is a description of investigations made by Devaux-Charbonnel of the frequencies of telephone currents with the object of establishing a basis for the theoretical study of telephone problems. He established the fact that the vibrations representing the voice have a period of considerable regularity, and he investigated the fundamental notes and harmonics of which the voice is composed. "After decomposing the current into its various sinusoidal harmonics, it becomes easy," the author states, "to foretell the effects that will be produced during their propagation over lines and through apparatus. It will be possible to investigate how the different periods are altered according to their frequencies and to see if these can not be compensated by a judicious choice of lines and apparatus and thus arrive at an ideal telephony, the transmission of the voice without weakening and with the preservation of its tone and all its modulations." In the experiments a Blondel oscillograph was employed to produce tracings of curves representing the current vibrations in a telephone circuit. Very clear curves two to four millimetres in height and corresponding to a duration of about one-tenth of a second were thus obtained. The distinctly periodical character of the curves was evident at first sight. The curves were next decomposed into their harmonics, the tracings being enlarged by a projection lantern in order to facilitate the process. It was found that the prominent indentations of the curves were equidistant, the different peaks evidently corresponding to a harmonic, which could then be easily eliminated. By repeating this process of elimination a curve was finally obtained which no longer contained a harmonic and represented the fundamental sound. It was found that with the vowels the fundamental sound is less intense than the harmonics, the second and sixth harmonic predominating, but with the vowels *u* and *i* harmonics as high as the thirteenth were observed. In syllables the presence of consonants modifies the curve during four or five periods. The observations led to the conclusion that the human voice is a sound rather than a noise; that it is formed by a succession of vibratory phenomena, the largest number of which are regularly periodical, and the telephonic currents transmitting the voice naturally partake of this same property and their study enters into the general theory of alternating currents. In short, the telephone currents consist of alternating currents of very different frequencies, caused by the fundamental sound and its harmonics. As to determining in advance the effects that will be produced over a given line, experiments have shown that all the harmonics are not equally important as regards intelligibility, and that only a small number is indispensable, but that those in the neighborhood of 1,200 are necessary to make speech intelligible. It was further demonstrated that the frequencies between 800 and 1,200 are really indispensable. An average frequency of 1,000 is, therefore, proposed as a basis for the study of practical telephone problems, and the general conditions making telephony possible should be adapted to this frequency. It will be necessary, however, in the treatment of a problem, to ascertain if the lower and higher harmonics will not give results too greatly at variance with those of the standard frequency of 1,000, and it would seem that consideration of the frequencies of 200 and 2,600, corresponding, respectively, to the average fundamental sound and the thirteenth harmonic, will furnish useful information in this respect.—*Translated and abstracted from La Lumiere Electrique (Paris), September 12.*

The Electric Lighting of Drury Lane Theatre Royal.

It will be remembered that on March 25 of the present year the stage of the historic Drury Lane Theatre, London, was completely destroyed by fire. The electrical equipment was almost entirely consumed, and directly after the insurance losses were adjusted, plans were drawn up and work inaugurated to restore the electrical fittings. A great deal of the present equipment is practically the same as that which obtained before the fire, but provision has now been made for duplicate services, one from the mains of the local supply company, and the other from the regular theatre system. A system of ventilation has been secured by which the draft of cold air which heretofore annoyed those sitting directly in front of the stage has been eliminated. Warm air is forced on the stage at any point where the cold air can possibly come into the stage or stalls. The air is drawn through sheets of moistened canvas, the canvas being fixed on a large horizontal drum kept rotating so that it is continually moistened with water. The air is then forced through a grid of pipes which are steam-heated, somewhat similarly to an air-cooled condenser. The heated air is finally supplied to the required point through ducts in the usual way. The electrical and hydraulic plants for operating the lifts and the dimmer room are located beneath the stage. The dimmer room contains three rows of dimmers, corresponding with the three colored lights. Each large dimmer controls 125 thirty-five-watt lamps, and each of the smaller dimmers controls sixty-two thirty-five-watt colored lamps. Metallic-filament lamps have been substituted for the carbon lamps, and these work well on the resistances occasioned by the dimming. Arc-lamp projectors are not used, there being some twenty oxyhydrogen projectors in the flies. The gas supply is drawn from large drums at a pressure of three pounds per square inch. These drums are recharged from ordinary gas cylinders. The battens which are now in use are a little out of the ordinary. There are twelve of these, each forty-two feet long, weighing 700 pounds, and containing 250 lamps. The feature of particular interest lies in the fact that they are only ten and one-half inches wide. All of the battens are earthed by making contact with the runners which form the guides for the counterweights on each side of the stage. For connecting up each batten a fuse-board is provided, having eleven circuits. This board is fed by two pairs of nineteen No. 16 cables, and one pair of nineteen No. 14 cables.—*Abstracted from the Electrician (London), September 18.*

INDUSTRIAL SECTION

ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Battery-Charging Rheostat.

The demand for a battery-charging rheostat which will not only meet all requirements of battery-charging service, but which shall possess automatic protective features as well, has led the Cutler-Hammer Manufacturing Company, of Milwaukee, Wis., to place on the market the panel here illustrated.

This battery-charging rheostat consists of a slate front mounted on an angle-iron frame containing the resistance, the whole being designed for attachment to a wall or switchboard.

The panel, which carries all of the operating mechanism, consists of three separate pieces of slate. On the face of the uppermost slate are mounted the terminals, or binding-posts, and a Weston voltammeter. The middle slate carries a double-pole knife-switch and fuses (National Electrical Code standard), and below these the contact segments and operating lever, by means of which the charging current is regulated. On the slate at the bottom of the panel are mounted the automatic protective devices, which are:

(1) A low-current cutout which automatically opens the circuit if the current drops to a predetermined minimum. This prevents the battery from discharging into the line should the line voltage drop below that of the battery.

(2) A maximum-voltage cutout. This automatically opens the circuit when the battery voltage reaches the point at which the cutout is set to operate.

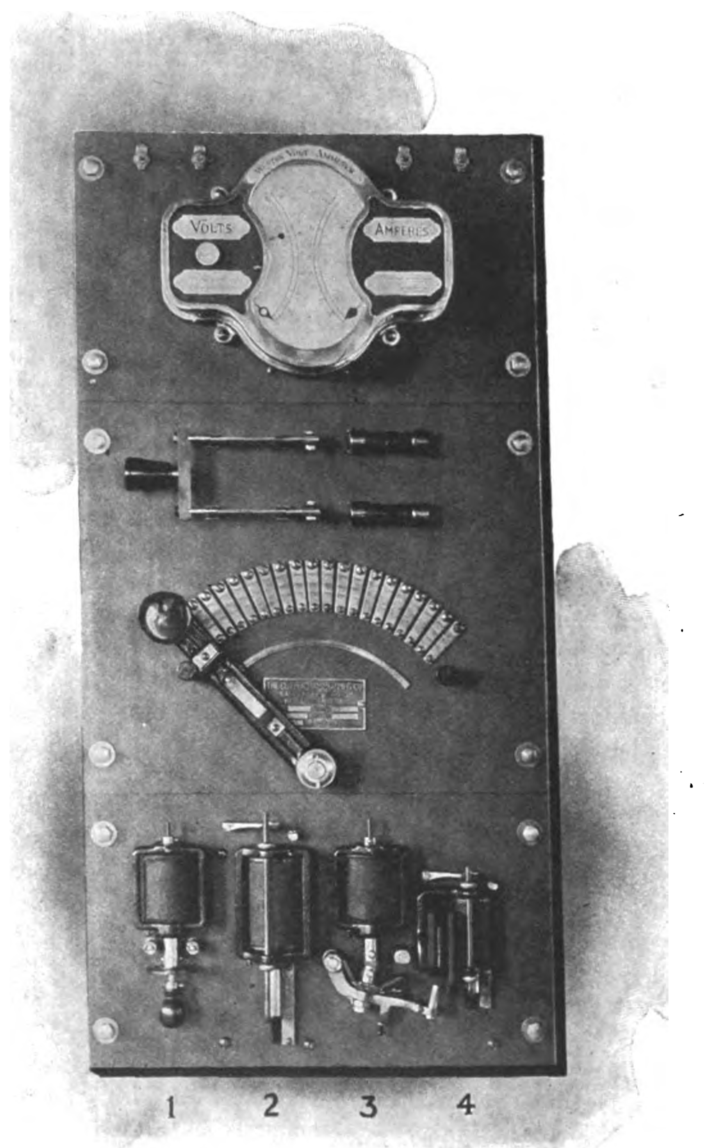
(3) A solenoid switch the opening or closing of which "breaks" or "makes" the main-line charging circuit.

(4) An overload circuit-breaker which automatically opens the circuit if the charging current rises to the point at which the breaker is set to operate. This insures the battery against being charged at an excessive rate.

The operation of this type of battery-charging rheostat is as follows: After the battery and line connections have been made the operator first closes the knife-switch and then moves the operating lever forward to the third-contact segment, at the same time raising the plunger on the low-current cutout (1), thus energizing the solenoid switch (3), which closes and permits the charging current to flow to the battery through the resistance.

If at the beginning of the charge the operating lever is not in the starting position (that is to say, resting against the rubber stop-post at the left) it must first be brought to the starting position and then moved to the third contact segment, as described above. It may then be moved further and further to the right, cutting out one step of resistance after another and increasing the amount of current until the desired amperage (as indicated by the ammeter) is obtained.

Should the current fail, or reverse, the low-current cutout (1) will release its plunger, thus de-energizing the solenoid switch (3), which will in turn open the main circuit. Should the charging current reach the point at which the overload circuit-breaker (4) is set to operate, this will open the main circuit. Finally, when the charge is continued until the battery reaches the voltage at which the maximum voltage cutout (2) is set to operate, this will automatically open the circuit, thus insuring the battery against an overcharge.



Battery-Charging Rheostat and Panel.

It will be evident from the above description that the use of this panel protects the battery under all charging conditions, as it not only guards against an excessive charging current, but also prevents the battery discharging back into the line should the line voltage fall below the voltage of the battery. It possesses, moreover, the advantage of requiring no attention after the charge is once begun, since the maximum-voltage cutout (2) will cut off the current of itself when the battery is fully charged.

As an additional protection the operating lever is provided with an electrical interlock, which prevents the operator from closing the circuit to the battery except when the lever is in the "off" position, that is to say, with all resistance in circuit.

These battery-charging rheostats are made at the New York works of the Cutler-Hammer Manufacturing Company, One Hundred and Thirtieth street and Park avenue, New York city.

Wagner Electric Manufacturing Company Central Station Transformers.

In an advertisement of the Wagner Electric Manufacturing Company that appeared in our columns last week, in referring to the efficiency of the central station transformers manufactured by that company, the phrase "Iron or copper losses are properly proportioned" should, of course, have read "Iron and copper losses are properly proportioned." In this connection it should be pointed out that the purchaser of a transformer can have, at his election, either extraordinarily low core losses, or extraordinarily low copper losses. Thus, the Wagner company has built, as an extreme of design, a 110-kilowatt transformer with a core loss of one-quarter of one per cent. Such a transformer, however, would obviously not do for any kind of ordinary service.

The Westinghouse Electric and Manufacturing Company Plan.

The modified plan of the Readjustment Committee of the Westinghouse Electric and Manufacturing Company has been made public. The detailed statement does not differ in any important points from the preliminary statement issued after the meeting of the Readjustment Committee last week. It is repeated that the adoption of the plan is contingent upon the raising of $6,000,000 cash by the stockholders by subscription to assenting stock, and that the consent of all the bank creditors must be obtained. Subscriptions to assenting stock now amount to $4,500,000.

Interests of the Westinghouse Company declare that now that the merchandise creditors' plan has been adopted in modified form by the Readjustment Committee, no difficulty will be encountered in obtaining the required subscriptions and assents from the bank creditors.

The Readjustment Committee of the Westinghouse Electric and Manufacturing Company submits the following statement of the company's present debt, exclusive of interest:

Unsecured debt:	
Convertible sinking fund five per cent gold bonds, due January 1, 1931	$18,500,000
Five per cent gold debenture ctfs., due July 1, 1913	1,969,000
Mdse. debt, including notes issued for mdse.	4,762,560
Bills payable for money borrowed	7,919,000
Total unsecured debt	$33,150,560
Debts secured by collateral:	
Three-year six per cent collateral notes, due August 1, 1910	$6,000,000
Ten-year five per cent collateral notes (French loan), due October 1, 1917	2,702,702
Total secured debt	$8,702,702

The modified or substitute plan for the readjustment of the debt of the Westinghouse Electric and Manufacturing Company contains the following features:

The funded debt is not to be disturbed.

The merchandise debt is to be satisfied by the merchandise creditors surrendering their claim in exchange for new assenting stock of the company at par.

Holders of the bank debt—notes payable for money borrowed—are to receive in exchange therefor one-half thereof in convertible sinking fund five per cent gold bonds of the present authorized issue at par, and for the other half either five per cent notes, in three equal amounts, maturing respectively in four, five and six years, to the extent of thirty per cent of the face value of the claim and for the balance of the claims assenting stock of the company at par, the creditor to have the privilege, however, of taking a larger amount of assenting stock and a lesser amount in obligations; or at the option of the creditor in respect to the one-half of the claim not covered by convertible bonds, five per cent notes of the company maturing in fifteen years.

In addition to the stock subscriptions payable by the surrender of debt, the company is to receive from stockholders and others subscriptions at par for $6,000,000 of assenting stock.

The committee has approved the following plan for the future management of the company:

1. The company to have a board of twelve directors, with power to add additional members to be distributed equally among the four classes hereinafter mentioned.

2. The board to be classified in respect of the tenure of office of its members so that there shall be four classes, the term of one class to expire each year.

3. The new board of directors to consist of persons approved by the Readjustment Committee with representation on the board of persons acceptable to the Merchandise Creditors' Committee.

4. The Readjustment Committee is to appoint a Proxy Committee, to remain in existence for five years, the members thereof to be chosen after a conference with the Merchandise Creditors' Committee and the principal stockholding interests.

The modified or substitute plan outlined above is not to become operative unless and until subscriptions to $6,000,000 of assenting stock and the necessary assents of the holders of the bank debt and merchandise creditors' claims are in hand, and the committee have fixed October 27, 1908, as the date by which such subscriptions and assents may be received.

The committee, however, may in its discretion impose such additional conditions or grant such additional extensions as may be necessary or proper to effect the readjustment of the debt of the company and to determine when assents of a sufficient number of creditors have been received to make it advisable to declare the plan operative.

The position of the company would be greatly strengthened if the plan could be completed immediately, and what should be striven for above all, by the stockholders particularly, is the elimination of the proposed four, five and six-year notes. A statement prepared by the auditor of the company, estimating the resources and requirements for five years beginning April 1, 1908, gives the minimum resources as $38,190,920, with probable resources of $54,090,920. The company's investments available for sale at sixty per cent of their book value total $2,415,800. The total requirements, under the merchandise creditors' plan, based on the bank creditors accepting twenty per cent of claims in assenting capital stock, are $33,811,700. This figure includes six per cent dividends on the assenting stock. The requirements under the same plan, based on the bank creditors accepting fifty per cent of claims in assenting capital stock, including six per cent dividends on assenting stock, are $31,579,785.

Delivery of securities may be made to the following depositaries: Bankers' Trust Company, New York; First Trust and Savings Bank, Chicago; the First National Bank of Pittsburg, and the National Shawmut Bank, Boston.

Some Products of the Massachusetts Chemical Company.

A product of the Massachusetts Chemical Company, Walpole, Mass., known as Walpole insulating board, is an interesting example of the evolution in quality of materials for the electrical trade.

This insulating board is, as its name implies, a solid insulating material manufactured in sheets of various thicknesses ready for use for all appropriate electrical insulating purposes, for which hitherto ordinary fibre board or other similar material has been employed. It "machines" well—that is, may be sawed, drilled and turned, and will hold a thread—and thus is adaptable to all the multifarious uses in electrical apparatus and machinery, and about central stations, calling for solid insulation in various shapes and sizes. The great feature of the material, however, is its inherent resistance to moisture, acids and alkalies, and oil.

That such a material fills a long-felt want is patent to every practical electrician. The wide adaptability of the product is attested by the extensive and growing use that is being made of it by the more progressive electrical manufacturers and engineers. The efficiency of the material in resisting the action of moisture and corrosive substances has been very strikingly shown by the performance of samples in the Chicago tunnels.

The value of this insulating material may be illustrated by the following examples of its use, taken from among many in which the maintenance of insulation, under continuous or temporary adverse conditions, is of the greatest importance:

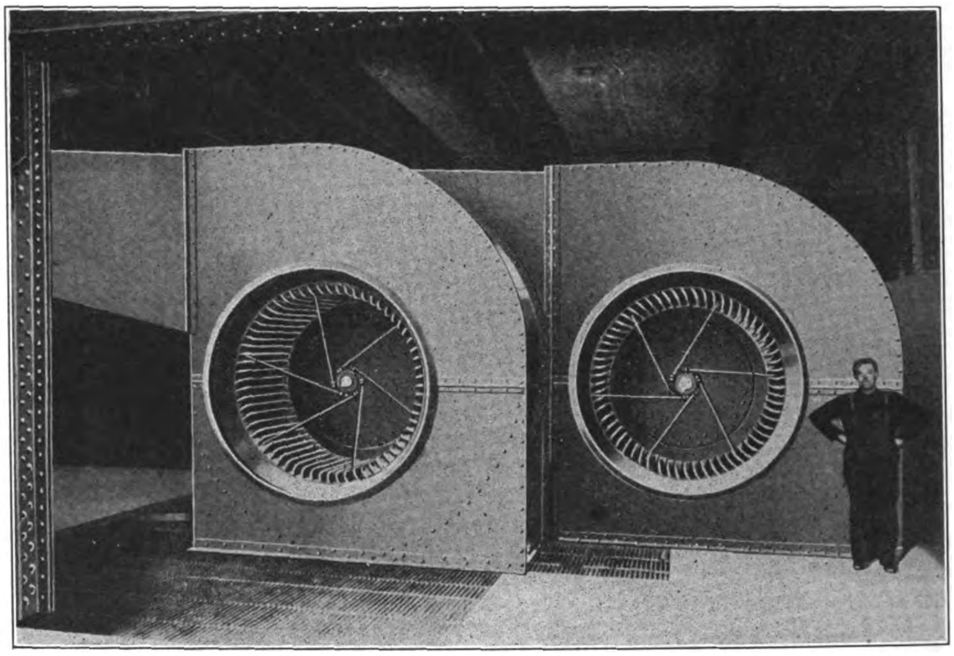
As a motor bed—in a slab extending underneath the entire base of the motor or as small plates under the four or more base-pads of the machine—this material gives assurance against grounds under any conditions. Dripping oil, dirty water, the muck that accumulates under a motor from sweepings, etc., which ordinarily endangers the insulation of the machine from ground, can not affect this material. Especially in damp locations, where the use of painted wood or ordinary slab "insulation" under the motor can not be counted on at all. As a base on which to mount field rheostats for generators and exciters, starting boxes for motors, potential regulators, and other similar devices.

Another product of this company is the Field-Coil Cushion. This device, which is designed to slip on over the field poles of railway motors, between the coil and the frame, prevents injury to the coil due to its movement on the core under the combined influence of the varying magnetization of the core and the vibration of the motor.

The field-coil cushion was developed by the Massachusetts Chemical Company about three years ago, at which time, in order to afford a practical test of the device, a single car of a well-known New England electric railway system was equipped. As a result of the performance of this test equipment, it was not long before these field-coil cushions were installed on the entire system.

Forced Draft Installation in Pennsylvania Terminal Power Station.

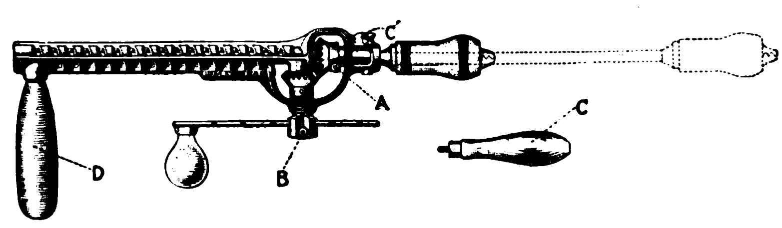
The installation made by Westinghouse, Church, Kerr & Company in the power station of the Pennsylvania Tunnel and Terminal Railroad Company, West Thirty-first street, New York city, is noteworthy for its space and power-saving features. Aside from the efficiency of the installation, saving in space was the most important element in this case, and led to the adoption of Sirocco turbine fans. Two special seventy-inch Sirocco fans are used in conjunction with Neomes grates. These fans deliver 82,000 cubic feet of air per minute against a pressure of two and one-half inches water gauge at 290 revolutions per minute. The fans, as will be noticed from the illustration, are of single-inlet type and are direct connected to horizontal engines.



SEVENTY-INCH SIROCCO FANS INSTALLED IN POWER STATION OF THE PENNSYLVANIA TUNNEL AND TERMINAL RAILROAD COMPANY.

A Telescopic Drill Brace.

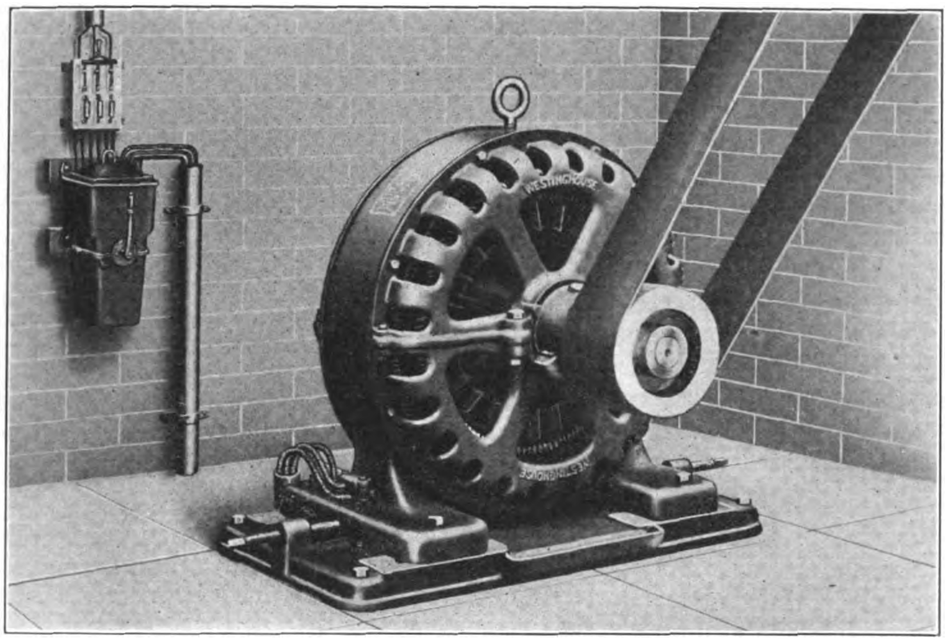
The accompanying illustration shows a telescopic drill brace which has been placed on the market by J. H. Rusby, 23 Boudinot street, Newark, N. J. This brace is instantly adjustable to three different lengths by pressing the latch on the shaft gear A and drawing out the shaft. The crank also is instantly adjustable by pressing the latch on the crank head B, to four, six, eight, ten or twelve-inch sweep. The length of brace over all, when closed, is sixteen inches, and, when open, twenty-five and three-quarters inches, with a stop midway between these extremes. The chuck is equipped with hardened alligator jaws, accommodating round-shank drills as well as square-shank drills and bits. The breast-drill handle C, when screwed into the frame, forms a breast drill. The rear handle D is removable by unscrewing.



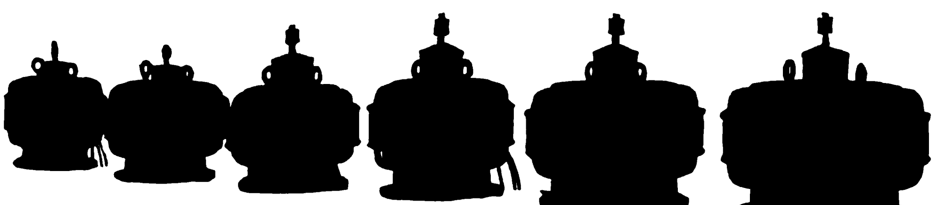
TELESCOPIC DRILL BRACE.

Westinghouse Type CCL Polyphase Induction Motors.

For many industrial installations polyphase induction motors of the squirrel-cage type offer distinct advantages. The absence of sliding contacts makes possible extremely simple construction, and the freedom from sparking assures this type of motor safe operation in places where inflammable gases exist or where inflammable material of any nature may be suspended in the atmosphere. The Westinghouse type CCL polyphase induction motors, manufactured by the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa., possess the advantages inherent with this type of machine, and are characterized by great strength of parts, large self-oiling bearings, high starting and pull-out torque, large overload capacity, low operating temperature, practically constant speed, and high efficiency and power-factor.



Westinghouse Type CCL Polyphase Induction Motor..



Type CCL Motors for Vertical Attachment.

Type CCL motors are built in standard sizes for slow and moderate speeds on two and three-phase circuits as follows: From one-half to 200 horse-power, inclusive, twenty-five and sixty cycles; from one to seventy-five horse-power, inclusive, forty cycles.

The frame consists of a cylindrical cast-iron ring having substantial supporting feet. Inside this ring are several lugs that support the stator core far enough from the frame to allow a good ventilating space between the frame and the core. The ends of the lugs and the frame are machined to receive the cast-iron bearing brackets, which are of the ventilated type, and which are bolted to the frame in such a way that they can be rotated through a ninety-degree angle. This permits mounting the motor on the floor, wall or ceiling.

The stator core or primary is built up of circular sheet-steel laminations punched from thin plates. These punchings are assembled, clamped and keyed between end rings inside the lugs on the frame. The stator windings generally consist of coils of insulated wire, form-wound; and before they are placed in the slots each slot is lined with insulating material..

The rotor core is built up of circular sheet-steel laminations, assembled, clamped and keyed between stiff end plates on the arms of the rotor spider. The rotor windings of all except the smallest frames consist of insulated copper bars, both ends of which are securely fastened to cast-metal end rings by copper-plated machine screws. The windings of the smallest sizes consist of insulated round copper rods riveted to the core end plates.

Ample ventilation is provided on every size, the end plates of the rotor cores on the larger sizes being provided with vanes or blades.

The bearings are liberally proportioned and lubrication is provided by supplying the split bearings with two oil rings, and the solid bearing with one oil ring.

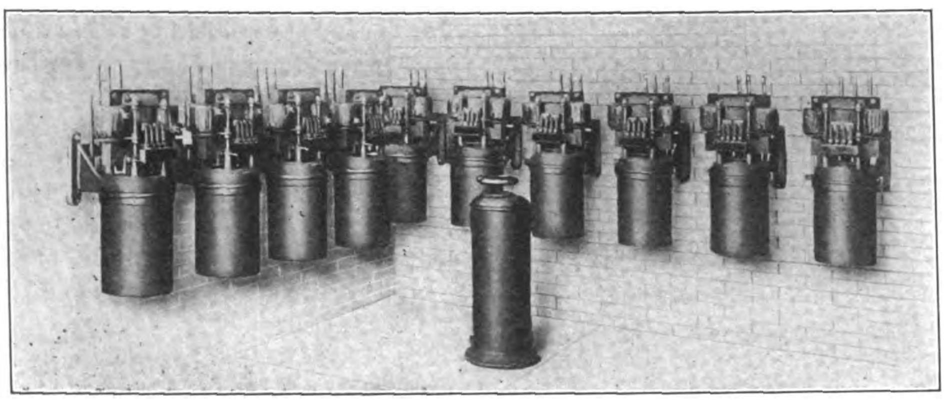
In order to supply a convenient method of driving certain types of machines such as vertical-shaft centrifugal pumps, a modified form of the type CCL motor is arranged for operation with the shaft vertical. The frame is a cylindrical casting without supporting feet. Each bearing bracket has ventilating openings near its outer edge. The upper bracket has a solid central section to prevent the entrance of foreign substances. This bracket carries a thrust bearing and a guide bearing. The lower bracket is cast with a flange or base for supporting the motor, and with ventilating openings in the central portion. This bracket also carries a guide bearing.

The ball thrust bearing carried by the upper bracket is capable of carrying something additional to the weight of the rotor, the exact amount of the excess weight depending on the size and speed of the motor. The weight is supported by balls rolling in a raceway between hardened steel discs, and spaced by a suitable brass cage. Attached to the upper end of the shaft is a thick steel washer, by means of which the weight of the rotor is transferred to the thrust bearing. The bearing is enclosed in a cup or bearing pot. The balls of the thrust bearing are immersed in oil. The cap over the top of the bearing pot carries a sight-feed oil cup, from which oil drops into a hole in the end of the shaft and is led to the upper guide bearing.

In many applications, especially where motors and lamps are supplied by the same circuit or transformer, large starting currents create undesirable fluctuations. For this reason it is not practical to apply full-line voltage to the motor primary in starting any but small squirrel-cage induction motors. Therefore each type CCL motor larger than five horse-power is provided with an auto-starter consisting of two auto-transformers and an oil-immersed switch for changing connections. All the parts are enclosed in a dust-proof cast-iron case.

The Westinghouse type E two-point auto-starters have been adopted as standard for use with all type CCL motors at standard voltages and frequencies up to 100 horse-power, and for sixty-cycle motors for 400, 550, 1,000 and 2,000 volts up to 200 horse-power. The auto-transformers are contained in the upper part of the cast-iron case, and the switch mechanism is attached to the same part. The lower part of the case forms the oil tank in which the switch contacts are immersed. The case is provided with lugs for mounting against a wall or column.

In special cases where CCL motors are required to start heavy inertia loads, more than two starting points may be advisable. For such installations the Westinghouse multi-point auto-starter, consisting of two auto-transformers in connection with a drum-type, oil-immersed contact-changing device, is supplied. The voltage is thus applied gradually to the motor in increasing steps. The contacts are made and broken under oil.



Single-Point Switch, Auto-Starters.

For type CCL motors up to fifty horse-power, driven by means of air-compressors, automatic multi-point auto-starters can be supplied. These differ from the multi-point auto-starters previously described chiefly in the method of operation. Each automatic auto-starter is equipped with an operating head which is actuated by the rise and fall of a liquid level or by the change of pressure in a closed-tank system.

New Business for Electrical Manufacturers.

In the following statement of orders placed by traction companies throughout the country for new equipment or improvements to existing apparatus, will be found an indication of more than ordinary significance when coupled with reports of returning activity in nearly all manufacturing lines. Electric railways are, normally, among the largest purchasers of machinery and other material, so that renewed buying on their part can not fail to be reflected in every department of industrial activity. To illustrate by specific instances:

The Omaha & Council Bluffs Street Railway Company recently placed an order for fourteen straight air-brake equipments. This is the second contract awarded the Allis-Chalmers Company by the Omaha City & Interurban line during the current year for straight air-brake equipments, and that the first to be installed are giving entire satisfaction is evidenced by the repeat order.

The Denison & Sherman Traction Company, Denison, Tex., recently changed the brake equipments on all of its cars, the new equipment being for straight air, with twenty-inch compressors of the same company's manufacture. The Northwestern Elevated Railway Company, of Chicago, has awarded a contract for air-compressors and governors for the twenty new cars now being built at the Pullman Car Company shops. The compressors will be of the Allis-Chalmers Type C-5 enclosed design, thirty-five feet capacity per minute, and the governors are the manufacturer's standard Type "OB" pneumatic. The Yonkers Street Railway Company, Yonkers, N. Y., recently placed an order with the Allis-Chalmers Company for twenty straight air-brake equipments. These include the new AA-6 sixteen-foot enclosed compressor and "OB" governor.

The Allis-Chalmers Company has also completed installation of automatic brake equipments on cars for the Niagara Gorge Scenic Railway, Niagara Falls, N. Y.; and, among others, additional orders for railway motors, controllers, compressors, governors or complete air-brake equipments have been received from the following railway and car-building companies: Winnebago Traction Company, Oshkosh, Wis.; Milwaukee Northern Railway Company, Cedarburg, Wis.; McGuir-Cummings Manufacturing Company, Paris, Ill.; New York, New Haven & Hartford Railway Company; New Orleans Railway and Light Company, New Orleans, La.; East Liverpool (Ohio) Railway and Light Company; Utica & Mohawk Valley Traction Company; Virginia Passenger and Power Company, Richmond, Va.; Roanoke Railway and Electric Company; Connecticut Company, New Haven, Ct.; Fremont City Railway Company, Fremont, Ohio; Eastern Pennsylvania Railway Company, of Philadelphia, Pa.; Springfield (Mass.) Street Railway Company; Interborough Rapid Transit Company, New York; Western Ohio Railway Company; Connecticut Valley Street Railway Company; Lehigh Valley Traction Company; Exeter, Hampton & Amesbury Street Railway Company; Lancaster (Ohio) Traction and Power Company; Indiana Union Traction Company; Interurban Railway and Terminal Company, Cincinnati, Ohio; Porto Rico Railways Company, San Juan, Porto Rico; Ohio Electric Railway Company; Angola Railway and Power Company, Angola, Ind.; Western Ohio Railway Company, Lima, Ohio; Worcester Consolidated Street Railway Company, Worcester, Mass.; Warren Street Railway Company, Warren, Pa., and Eastern Ohio Traction Company.

Among companies making large additions to their power equipment or taking advantage of the present excellent opportunity to bring their generating stations to a state of higher efficiency are the following:

Winona Interurban Railway, Warsaw, Ind.; New Jersey & Pennsylvania Traction Company, Trenton, N. J.; Wausau Street Railway Company, Wausau, Wis.; Chicago, Indiana & Southern Railway; Petaluma & Santa Rosa Railway Company, Petaluma, Cal.; Indianapolis, Columbus & Southern Traction Company, and others.

Another feature of the situation which is of interest, reported by the company as builder of the Gates gyratory breaker, is the fact that quite a number of traction companies having their own rock-crushing equipment, or allied interests in control of it, have been putting it in good repair as well as adding to it. Evidently it is with the intention of materially improving roadbeds during the remaining open months. There is also considerable activity noticeable among the creosoting plants where ties are treated, and, as the steam roads are doing very little at present, considerable of this must be due to orders from electric traction companies, particularly those of the Middle West, where the financial depression does not seem to have been so severely felt as elsewhere.

Current Electrical News

DOMESTIC AND EXPORT.

A TWELVE-MILLION-DOLLAR POWER COMPANY FORMED—With a capital of $12,000,000 the Nebraska Power Company has been incorporated in Delaware. The purposes are to construct and operate hydroelectric power plants, with everything pertaining thereto. The incorporators of the company are: B. E. Babcock, Columbus, Neb.; W. J. McEathron, Omaha, Neb., and Harry W. Davis, Wilmington, Del.

POWER PLANTS FOR UPPER SKAGIT RIVER—It is announced that surveys are under way on the upper Skagit River, Wash., for power plants which will develop from 75,000 to 100,000 horse-power. Colorado capitalists and an English syndicate are said to be behind the movement. Water rights have been taken out on the Skagit River and on its tributaries above Bacon Creek. A surveying crew under the direction of C. L. Mitton, a Colorado civil engineer, is running a line for a three-mile tunnel which will have its down-stream end near Rockport. By means of this tunnel a 250-foot head will be secured. The first step to be taken in the project will be the erecting of a 10,000-horse-power plant at the intersection of Bacon Creek with the Skagit River. The power developed here will be used in the work of developing the larger power plant further up-stream. The locators of the water rights are: A. Freeman, of Anacortes, and B. Thomas, of Seattle, Wash.

MEXICAN ELECTRIC MERGER—F. S. Pearson, president of the Mexico Tramways Company, and vice-president of the Mexican Light and Power Company, states that the proposed merger of the two companies will probably be effected on January 1. Meetings of the stockholders will be held within a few weeks to vote on the matter. The Necaxa power plant will be increased from 40,000 to 100,000 horse-power if the merger is carried through, according to a statement by Mr. Pearson. Heretofore the plans have called for an increase of only 20,000 horse-power, instead of 60,000. The increase will be obtained by using the same water over and over again. Work is now under way on a power plant above the present plant, which will use the water for the first time. A third plant will be built below the present one, the two new power-houses furnishing the 60,000 increase in horse-power. Mr. Pearson forecasted that the tramways company would spend over $5,000,000 in the Federal district alone in improving the tramways and electric light property, if the merger is agreed upon.

INTERSTATE RAILWAYS COMPANY TO EXTEND SYSTEM—Arrangements are being made by the Interstate Railways Company, of Philadelphia, Pa., which controls an electric railway system of about 450 miles in eastern Pennsylvania, for important improvements and extensions. The Reading Power Company is to issue $1,500,000 first mortgage bonds, guaranteed by the United Traction Company of that city. Proceeds of these bonds will be expended on a new power plant at Reading having a capacity of 20,000 kilowatts. This power will operate the lines from that city down to Chestnut Hill, as well as in the Lebanon Valley. Refinancing plans of the Interstate Railways Company which, it is understood, will be underwritten by E. B. Smith & Company, contemplate several extensions of the present system. One of these will be a new line twenty miles long, from Reading to Hamburg, at a cost of $400,000. The Wilkes-Barre & Wyoming Valley system will be extended from Pittston to Avoca, and from Miners Mills to Hudson. Rights of way have been secured for these three extensions.

NEW CALIFORNIA ELECTRIC ROAD—Articles of incorporation have been filed by the California Company, which proposes to build and operate a railroad, either steam or electric, between Marysville and Sacramento, Cal., the line to run through Marin, Sonoma, Napa, Solano, Yolo and Sacramento counties, its total length to be ninety-five miles. The incorporators of the California Company are: C. W. Conlisk, R. A. Morton, C. H. Lind, L. N. Pryor, George James, Frank E. Cornice and Russell B. Sage. Of the capital of $2,500,000, the sum of $150,000 has been subscribed. Richard Hotaling is the promoter of the enterprise. Conlisk is the manager of the Hotaling estate. After a trip to the East in the summer of 1907, Hotaling began active work on his system and it was announced that he had made arrangements for the expenditure of $9,000,000 on a network of electric lines in the bay counties. One of the branches will run from Gallinas Creek in Marin County to Petaluma, a distance of eighteen miles, and the other will extend from Napa to a station five miles distant from that place.

MERGER OF ELECTRIC COMPANIES—Negotiations have been completed whereby the Northern California Power Company will take over all the rights and physical properties of the Keswick Electric Power Company, Battle Creek Power Company, Redding Light and Power Company, and Willows Water and Light Company, which have been operated for years past by the Northern company, of which H. H. Noble, of San Francisco, Cal., is president. With a bond issue of $3,000,000 it is intended to retire the bonds at present outstanding in the companies named and also to proceed with the installation of work under construction and contemplated. It is expected that the full installation will be completed early in December of this year when 13,000 horse-power will be available. The present horse-power generated is 10,000. Twenty-six towns in the counties of Glenn, Butte, Tehama and Shasta, besides isolated pumping stations consuming from five to fifty horse-power, are served. There are also long-term contracts calling for 14,600 horse-power, deliverable to mines, smelters and factories. The water rights owned by the system have a capacity of 150,000 horse-power. A meeting of stockholders will be held on October 12 to vote on the proposed consolidation.

NEW INCORPORATIONS.

DOVER, DEL.—Center Valley Power and Light Company. $100,000.

COLUMBUS, OHIO—Scioto Valley Traction Company, Columbus. Increase of capital stock from $3,000,000 to $3,500,000.

GRAFTON, W. VA.—People's Mutual Telephone Company, of Romney, W. Va. $10,000. Incorporators: J. D. Byre, W. N. Guthrie, James C. Heath, C. H. Cookus, K. Taylor and J. M. Millison.

WILMINGTON, DEL.—Johns River Heat, Light and Power Company, Wilmington. $500,000. Incorporators: Elisha W. Meloney, Avondale, Pa.; Benjamin F. Groff, Lancaster, Pa.; Charles B. Evans, Newark, Del.

HARRISBURG, PA.—Wiconisco Electric Light, Heat and Power Company, of Wiconisco township. $5,000. Incorporators: John Pfeiffer, G. Schoffstal, A. W. Long, R. Sterling, P. Maher, H. T. Beistline and B. W. Fells, of Tower City.

OAKLAND, CAL.—Tuolumne Water Power Company. $1,000,000. Directors: Warren Gregory and H. H. Rolfe, of San Francisco; Winfield Dorn, of Oakland; George H. Whipple, of Alameda, and J. S. Lamson, of Berkeley. To develop electric power at the head waters of the Tuolumne River for use in the cities about the bay.

COLUMBUS, OHIO—Springfield Light, Heat and Power Company. To take over the People's Light, Heat and Power and the Home Electric Lighting companies, of Springfield. $1,000,000. Incorporators: J. D. Price, W. H. Sharp and L. M. Ferguson, of Columbus; and W. W. Keifer, C. S. Kay and F. M. Hagan, of Springfield.

LOGANSPORT, IND.—Logansport, Frankfort & Indianapolis Traction Company. $25,000. To build an electric line from Frankfort, Ind., north to Logansport, thirty-five miles. Directors: S. H. Blakeslee, Allen G. Barane, Eben Miller, Frank Sargent, all of Cleveland, Ohio; William W. Palmer, New York; Ephraim A. Thomas, Pittsburg, Pa., and W. P. Clark, Kent, Ohio.

ELECTRIC RAILWAYS.

STERLING, ILL.—Work has been begun on the grading for the new electric line from Tampico to Hooppole.

STOUGHTON, MICH.—At a special meeting of the council the Cincinnati Construction Company was granted an interurban franchise.

SACRAMENTO, CAL.—The Sacramento Terminal Company has been organized to build the freight tracks and bridge of the Northern Electric Company in this city.

FORT WAYNE, IND.—It is said that $50,000 additional stock has been subscribed for the extension of the Fort Wayne-Decatur trolley line southward from Decatur to Berne.

BOISE, IDA.—The Boisé & Interurban is engaged in purchasing additional land along the entire right of way to Pierce Park with a view to double-tracking the park line in the spring.

CHAMBERSBURG, PA.—The Chambersburg & Western Trolley Company has decided to build its line from Chambersburg to St. Thomas and Edenville, provided the right of way can be secured without too great expense.

COOS BAY, ORE.—L. J. Simpson, of North Bend, has secured a franchise from the county court for the use of the public highway between Pony Slough and Sunset Bay for an electric line. Mr. Simpson will probably begin construction next spring.

ALBANY, N. Y.—The Public Service Commission has granted the application of the New York & North Shore Traction Company for approval of construction and extension work on its street surface railroad from Hicksville to Mineola, in the county of Nassau.

ATLANTA, GA.—The Knickerbocker Trust Company, New York, has asked the United States Court to foreclose its mortgage on the property of the Gainesville (Ga.) Electric Company. The Knickerbocker company holds a mortgage to secure an issue of $400,000 in bonds.

CANTON, OHIO—John Monnot, the well-known electric railroad man of Canton, is authority for the statement that within a year there will be an electric railroad operated upon a private right of way paralleling the line of the Mahoning Valley from Youngstown to Warren.

FREDONIA, N. Y.—The Buffalo & Lake Erie Traction Company has let contracts for three power stations on its line from Silver Creek to Westfield, to the Bailey Contracting Company, of Brocton. One will be at Silver Creek, one midway between Dunkirk and Fredonia, and one at West Portland.

CHOUTEAU, MONT.—At a special meeting of the county commissioners a franchise for an electric line was granted to G. Calvin Bower, of Great Falls, or to any corporate body which may succeed him. The franchise permits the use of the public highways of Teton County and covers a period of forty years.

PHILADELPHIA, PA.—The Pennsylvania & Maryland Street Railway Company has started work on its line which will be built from Myersdale to Johnstown by way of Currott, Berlin, Somerset and Boswell. When this is completed, the line will be extended to connect with the Piedmont & Cumberland electric line.

WASHINGTON, D. C.—A new building is to be built for the Capital Traction Company at First and B streets, southwest. The contract, which calls for an expenditure of about $30,000, has been awarded to James L. Parsons. The building will be two stories high and will have a frontage of thirty feet and a depth of eighty feet.

SCRANTON, PA.—Work has been started on the power plant of the Scranton Railway Company, which it is planned will provide, when completed, not only all the power now needed but meet the increasing demands on the system that will come with the growth of the city. The plant when completed will cost not less than a half million dollars.

ALBANY, N. Y.—The Public Service Commission, Second District, has authorized the Rochester, Corning & Elmira Traction Company to sell $1,000,000 bonds. The commission required, as a condition to this consent, that $380,000 stock of the company should be subscribed by responsible parties before any bonds were issued. The company has complied with this requirement.

EL PASO, TEX.—Richard Caples was granted a franchise and the right of way for an interurban from the New Mexico line, near Anthony, to Fabens, and sets forth that work shall commence at El Paso within six months from the time such franchise was granted. and that the line shall be completed to within a mile of the Catholic Church at Ysleta within eighteen months.

BLOOMINGTON, ILL.—The Illinois Traction System is contemplating improvements for its lines entailing a cost of several thousand dollars. The improvements are either under way or about to the promulgated. The company has decided to complete the Decatur belt railway system and install new machinery in the power-house at that city. A new boiler house will also be erected.

MILWAUKEE, WIS.—The Milwaukee-Northern Railway Company has placed in operation its line from Milwaukee to Sheboygan. The company will double-track its road from Milwaukee to Brown Deer, a distance of ten miles, to accommodate the increasing business on that part of the line. Work of grading the road for the second track is under way, and the rails will be laid to begin the service early in 1909.

COLUMBIA, MISS.—The directors of the Mexico, Santa Fé & Perry Traction Company, at a recent meeting elected officers, and they also discussed the plan for extending the road to Columbia. This company holds a franchise in Audrain, Monroe and Ralls counties and some of the grading has been done. The officers are: President, Mathias Crum; secretary, G. W. Gaither; treasurer, Judge W. W. Botts; general manager, S. L. Robinson.

NEW YORK, N. Y.—A. V. Porter and J. R. Spelman, architects for Adrian Joline and Douglas Robinson, receivers of the Metropolitan Railway Company, have filed plans for a new car house to replace the old Ninth avenue structure, which stood for half a century on the corner at Fifty-fourth street. It will be of brick and ornamental stone, 135 feet 10 inches by 298 feet 10 inches, five stories high in the main part and three in the annex. It will cost $450,000. Two stories will be built at once at a cost of $300,000.

MINEOLA, L. I.—By request of counsel for the New York & North Shore Traction Company, the Nassau supervisors have granted the company an extension of six months on its franchise to build and put in operation a trolley line from Roslyn to Manhasset. The franchise is based on the contingency that the company shall obtain a franchise from the New York city authorities to extend the line beyond the city limits. The company has not been able to obtain the city franchise yet, but hopes to within the coming six months.

CAMBRIDGE SPRINGS, PA.—The Titusville Traction Company will build a line between Cambridge Springs and Titusville, touching Hydetown, Clappville, Little Cooley, Teepleville. The road is already completed to within one mile of Tryonville, where a branch will extend north to Union City. The company has made arrangements to co-operate with the Meadville Traction Company, the Erie Traction Company and the Erie Railroad at Cambridge Springs. Contracts are being made with the Wells Fargo Express Company to handle express matter.

PATERSON, N. J.—John R. Lee, of Paterson, has been awarded a contract to build a fifteen-mile traction line between Paterson and Suffern, and finish it in four months. The president of the company behind this line is William Barber, of Paterson, and the vice-president, Malcolm R. McAdoo, of Montclair. This is to be the nucleus of a high-speed third-rail electric line to be built later between Hoboken and Paterson by the New York & New Jersey Rapid Transit Company as soon as the needed capital can be obtained. The total cost of the Paterson-Suffern branch is estimated at $500,000.

BEAVER, PA.—A company has been formed to build a line from Pittsburg to East Liverpool over an airline route. The distance over the new route is thirty-four miles, ten miles less than by any railway or electric line now existing. The new company is known as the Pittsburg & East Liverpool Electric Railway and the officers are Professor J. M. Reed, Dravosburg, president; Rev. A. Moore Buchanan, Morgantown, W. Va., secretary, and Hon. J. H. McClaren, of Murdocksville, treasurer. A large amount of money has been raised by those living along the proposed line to make a complete survey, and rights of way have been given.

PERSONAL MENTION.

MR. EUGENE CREED has resigned from the new-business department of the Narragansett Electric Lighting Company, of Providence, R. I., and has accepted a position as sales agent with the Auburn Light and Power Company, of Auburn, N. Y.

MR. I. B. WHITE, of Alexandria, La., has been made manager of the Alexandria Electric Railway Company. He was formerly owner of a private telephone system in the town of Winnfield, La. The company has ordered rail for an extension two miles west of the city.

MR. J. D. EDMONDS has resigned his position with the Western Electric Company, Chicago, Ill., where he was associated with both the operating and sales departments for several years, and accepted the position of superintendent of works with the Sterling Electric Company, of Lafayette, Ind.

MR. WILLIAM M. DUANE has resigned his position as chief engineer of the Big Four Railroad, to take effect November 1. He will become vice-president and general manager of the Walsh Construction Company, of Davenport, Iowa, which will construct an extensive electric railway system.

MR. HARRY MUNN SLAUSON, of the inspection department of the New York Edison Company, has accepted a position with the Enos Company, manufacturer of lighting fixtures. Mr. Slauson represented the Enos Company at the New York Electrical Show, introducing the company's new fixtures and electroliers.

MR. J. P. PULLIAM, of Oshkosh, Wis., has been appointed general superintendent of the East Wisconsin Electric Railway and Light Company, of Fond du Lac. Mr. Pulliam is also general superintendent of the Wisconsin Electric Railway Company, of Oshkosh, formerly the Winnebago Traction Company. These two roads have a traffic arrangement, and Mr. Pulliam will have general charge of both systems.

MR. HORATIO A. FOSTER, who for the past year and a half has been in charge of the Baltimore office of L. B. Stillwell as resident engineer, has resigned and become connected with the valuation department of the Public Service Commission, First District, New York. This department is under the direction of Bion J. Arnold, of Chicago, and is evaluating the surface car lines of Manhattan and the Bronx.

MR. H. W. WORTHLEY, who has been district superintendent of the Salem district of the New England Telephone and Telegraph Company, comprising Salem, Beverly, Gloucester and Newburyport exchange districts, has been appointed district manager of the Manchester, Concord, Franklin, Laconia, Claremont, Newport, Rochester, Portsmouth, Dover, Exeter and Nashua exchange districts. R. Robins, Jr., formerly manager at Lynn and now district superintendent of the first suburban district of the Boston division, has been appointed district manager of the Salem district.

DATES AHEAD.

American Street and Interurban Railway Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Accountants' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Claim Agents' Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Engineering Association. Annual convention, Atlantic City, N. J., October 12-16.

American Street and Interurban Railway Manufacturers' Association. Annual convention, Atlantic City, N. J., October 12-16.

Railway Signal Association. Annual meeting, Washington, D. C., October 13-15.

Order of the Rejuvenated Sons of Jove. Annual meeting, Buffalo, N. Y., October 15-16.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October 20-23.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Association of Car-Lighting Engineers. First annual meeting, Chicago, Ill., November 18.

National Society for the Promotion of Industrial Education. Annual meeting, Atlanta, Ga., November 19-21.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

ELECTRICAL SECURITIES.

Last week's stock market was marked by dull, narrow and irregular price movements, with values inclined to fall, if anything. Professional operations ruled almost entirely, and the public indifference was very manifest. Toward the end of the week conditions showed a little more animation, but the whole situation is so thoroughly and completely dominated by political possibilities that it is quite impossible to predict which way things will turn in the immediate future. It appears also that trade improvement has been somewhat halted by the election uncertainty, although there is no change of moment to record in the monetary situation or outlook. No radical change is expected in the crop reports, and the promise is that, while the harvest will not be record-breaking in proportions, as was indicated in the earlier part of the year, it will still be of such abundance that the agricultural interests will have good reason to be well satisfied.

Dividends have been declared upon the following electrical securities: Mexican Light and Power Company; directors have placed the common stock on a 4 per cent basis, declaring a quarterly dividend of 1 per cent. Standard Underground Cable Company; regular quarterly dividend of 3 per cent, payable October 10. Shawinigan Water and Power Company; quarterly dividend of 1 per cent. A quarterly dividend of 2½ per cent on the stock of the Brooklyn City Railroad Company, guaranteed under the terms of the lease by the Brooklyn Rapid Transit Company, payable October 15.

ELECTRICAL SECURITIES FOR THE WEEK ENDED OCTOBER 3.

NEW MANUFACTURING COMPANIES.

BOSTON, MASS.—The International Telephone Company has been incorporated with a capital of $200,000 to deal in electrical goods. H. I. Hahn, of Boston, is president, and A. H. Cobb, of Lynn, treasurer and clerk.

AUGUSTA, ME.—The American Annunciphone Company has been organized at Portland for the purpose of manufacturing and dealing in telegraph, telephone and electrical supplies of all descriptions, with $500,000 capital stock, of which nothing is paid in. The officers are: President, T. L. Croteau, of Portland; treasurer, F. H. Morrill, of Portland.

ELECTRIC LIGHTING.

WEATHERFORD, TEX.—The city council has awarded a contract to the electric light company for three arc and ten Nernst lamps.

CADDO, OKLA.—The light plant at this place, which was shut down several months ago, has been taken over by O. Q. Moon, of Caddo.

MORENCI, MICH.—The Morenci electric light plant was sold at the Adrian court house recently for $3,500 to G. F. Avis and Mills Lamb, of Hudson, who will improve the system.

WAKEFIELD, MASS.—A new switchboard will be installed at the municipal lighting plant at a cost of $3,500, and eighty-seven arc lamps will be replaced with 400 forty-candle-power units.

SMITHVILLE, TEX.—The Missouri, Kansas & Texas Railway Company is preparing to put in its own electric light plant for the shops at this place. The plant will furnish 100 lights of sixteen candle-power.

CUMBERLAND, WIS.—The contract for erecting a new building for the lighting plant and the installation of the necessary machinery has been let by the common council to J. R. Robertson, of St. Paul, Minn., for the sum of $17,000.

EUREKA, UTAH—The Telluride Power Company will begin work shortly on a new transmission line from its substation in Eureka to the Tintic smelter, which will give the latter two sources on which it can rely for electric power.

BUCYRUS, OHIO—It is expected that specifications for the proposed municipal lighting plant at Bucyrus, for which $90,000 in bonds was recently voted, will be issued about November 1, when it is thought the bonds will have been disposed of.

GOSHEN, IND.—Disregarding injunction proceedings brought against the city, Robert E. Ashe, of Richmond, Ind., who has the contract for rebuilding the municipal lighting plant here at a cost of $32,700, is preparing to go ahead despite the court proceedings.

MAGAZINE, ARK.—The Magazine Gin and Grist Company is preparing to install a system of electric lighting in Magazine. Power for running the lighting system will be obtained from the machinery already in use in furnishing power for the gin and grist mill.

FAIRMONT, W. VA.—The Fairmont & Clarksburg Traction Company has been awarded a contract by the city council for a minimum of ninety street arc lamps at $55 each. This provides for the addition of thirty lamps. The company now has a contract which has still two years to run.

MARYSVILLE, CAL.—The Great Western Power Company, whose line passes through Marysville, has begun stretching wires along its tower line from Big Bend to Oakland. The power company has also started work on the erection of a $2,000,000 auxiliary steam power plant on Session's basin, in Oakland.

TEMPLE, TEX.—Local capitalists, whose names are withheld for the present, are forming a company for the purpose of establishing a new electric light and power plant in this city, which may also supply Belton. As soon as plans are far enough along application will be made to the city council of Temple for a franchise.

LAUREL, MD.—Wallace Stebbins & Sons, of Baltimore, were the successful bidders for the construction of the new electric lighting plant to be in operation here about November 15. Their bid was $11,766. C. L. Reeder, of Baltimore, appointed several months ago by Mayor William E. Gilbert, is engineer in charge of the work on the new plant.

CHARLOTTE, N. C.—The Louise Mills have been equipped with motors of 750 horse-power and a substation is being built from which electricity will be supplied to the mills. These mills operate about 600 looms and 27,000 spindles. The Chadwick-Hoskins Company, the owner of this plant, will similarly equip several of its mills which, combined, operate about 100,000 spindles and 2,300 looms.

ALBANY, N. Y.—The Public Service Commission, Second District, has granted the application of the Plattsburgh Light, Heat and Power Company for authority to dispose of an issue of $250,000, recently authorized, at eighty-five instead of ninety, as required in the original order. It was shown that the company was unable to dispose of the bonds at ninety, but has found a market for them at eighty-five.

BALTIMORE, MD.—A move is on foot to extend the service of the Patapsco Electric and Manufacturing Company to cover Mount Washington, Arlington and West Arlington, and later take in other territory in that section of Baltimore County, which is now supplied with electric current by the Mount Washington Electric Power Company, a subsidiary of the Consolidated Gas, Electric Light and Power Company.

WILKES-BARRE, PA.—Arrangements have been completed by which the Scranton Electric Company secures control of the Lackawanna Valley Electric Light and Power Supply Company, of Carbondale. The company controls all the electric light plants between Pittston and Carbondale, with the exception of a couple of municipal plants in the small towns of the upper valley. C. D. Hubbard, of Scranton, is now general manager at Carbondale.

BUFFALO, N. Y.—The Appellate Division, in session at Rochester, has handed down a decision affirming the judgment of the Supreme Court entered on the decision of Justice Marcus last May in the action brought by the Economic Power and Construction Company against the city of Buffalo, Commissioner of Public Works Ward and Chief of Police Regan restraining the defendants from interfering with the Economic company in the construction of its plant in the city of Buffalo.

ST. LOUIS, MO.—Following the decision of City Counselor Bates that the electric light and power franchise of Browning, King & Company is valid, the West End Light and Power Company, which now owns the franchise, has filed a bond for $20,000 as a guarantee that it will comply with the provisions of the Keyes ordinance. The company now has an application pending before the board of public improvements for permits to string electric light and power wires in the district bounded by Lindell avenue and Sarah street and King's Highway.

PAWTUCKET, R. I.—Acting under authority of the city council, the joint standing committee on street lights has executed a ten-year contract with the Pawtucket Electric Company for the lighting of the streets by electricity. The old contract expired about five years ago, and since that time the city has been paying for its lights at the same rate. The new contract is in effect and under it the price per light for the lamps that burn all night is $105, the old price having been $112.50. For the lights on the one-o'clock circuit the new price is $70 per light, as compared with $72.50 under the old contract.

BUENA VISTA, VA.—At a meeting of the city council a franchise was granted to the Rockbridge Power Company to furnish power and lights to the citizens of this place. The Rockbridge Power Company is composed of W. G. Mathews and several citizens of Clifton Forge, and it is their intention to develop the water power on the North River, several miles below town, and to furnish power and lights to Buena Vista, Glasgow, Buchanan and possibly Lexington. They will install substations in each of the above-named towns. Owners of several small industries who contemplate locating in Buena Vista have applied for power. Work on the dam will begin at once.

ZANESVILLE, OHIO—It is announced that eastern capital has become interested in the Central Valley Light and Power Company and that the company has been financed. Actual construction work will commence early in the spring. The site of the plant will be opposite the railroad station at Philo. The building, completed, will cost $165,000. Over nine miles of pole-lines will be installed. The greater part of the current generated will be distributed in the vicinity. Enough bonds have been issued to erect the power plant without delay. The plant will also furnish power for the Central Valley Electric Railway, which it is proposed to construct from this city to down-the-river points.

KENNEWICK, WASH.—It is announced that the local electric light and water plants, owned by the Kennewick Electric Company, have been purchased by the Northwest Light and Power Company, which owns and operates electric plants throughout the Inland Empire. It is also asserted that the new organization will be known as the North Coast Electric Company. President Strahorn, of the North Coast, is president of the Northwest Light and Power Company. The plants in this city are being enlarged and will be made of sufficient capacity to furnish lights to Pasco, where the electric plant recently burned. Machinery is now being installed and it is announced that the work of enlargement will be carried on rapidly.

KILLINGLY, CT.—Massachusetts, Connecticut and Rhode Island capitalists are behind the Nashawaug Electric Power Company, which is to establish a power plant near Ballouville in the northeast part of Killingly. The company has acquired the Sabin L. Sayles water-power privilege, located between Dayville and Attawaugan, and will reserve it for future development. The Attawaugan company, which manufactures cotton goods and which operates plants at Ballouville and Attawaugan, has negotiated a contract to take electric power from the Nashawaug company for twenty-five years. Arrangements will be made later to distribute electricity for light and power purposes in Killingly, Plainfield, Canterbury and Griswold. The Nashawaug company has authorized an issue of $37,500 of six per cent cumulative preferred stock and $112,500 of common stock. It has also authorized an issue of $100,000 five per cent bonds. Grosvenor Ely, of Norwich, is president of the corporation; Frank B. Perry, of Boston, is secretary, and Frederick Taber, of New Bedford, is a member of the board of directors.

TELEPHONE AND TELEGRAPH.

ANDREAS, PA.—The Bell Telephone Company will extend its line to Andreas.

HILLSBORO, ILL.—The stockholders of the People's Mutual Telephone Company have selected C. E. Landers, of Coffeen; W. R. Gunn, of Raymond, and Victor A. Bost, of Fillmore, as directors.

MARSHALLTOWN, IOWA—The city council has granted a franchise to the Farmers and Merchants' Telephone Company to enter Marshalltown. A $200,000 plant will be installed if the franchise is accepted by the people on November 3.

BRENHAM, TEX.—The Brenham & Long Point Telephone Company has completed its line and is now connected with the Southwestern exchange of this city, giving it complete service from Brenham to Long Point, and from there to Burton and Gay Hill.

DOYLESTOWN, PA.—The Bell Telephone Company has rebuilt its trunk lines from Doylestown to Newtown, including way trunks to Wycombe and Buckingham. All the iron wires have been replaced by copper wires. The poles and wires of the old Standard company have been abandoned.

TROY, N. Y.—Announcement is made that an operating agreement has been made between the Hudson River Telephone Company and the Champlain Telephone Company. The Champlain company operates a system in Plattsburg, Malone, Montreal and important towns in northern New York. An agreement has also been entered into with local telephone companies at Chazy and other small places in the Adirondacks by which the facilities and service of the Hudson River-Champlain telephone combine are rendered available to their subscribers.

INDUSTRIAL ITEMS.

THE WESTERN ELECTRIC COMPANY, Chicago, Ill., is distributing two handsome bulletins, devoted, respectively, to electrical equipment for hotels and department stores.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., in bulletin No. 4,617, describes and illustrates direct-connected generating sets. Copies of this bulletin will be forwarded to those interested upon request.

THE HOYT ELECTRICAL INSTRUMENT WORKS, Penacook, N. H., has issued a new catalogue devoted to the Hoyt volt-ammeter for ignition testing. Copies of this bulletin will be furnished to those interested upon request.

I. P. FRINK, 551 Pearl street, New York city, has issued a catalogue, No. 56, devoted to Frink's special reflectors for tungsten lamps. These lighting units have some exceptional features and are meeting some very exacting requirements in illumination. Copies of this catalogue will be furnished on request.

THE TUNGSTOLIER COMPANY, Citizens' Building, Cleveland, Ohio, is distributing regularly a Tungstolier talk devoted to some important phase of illuminating engineering. This new lighting unit, equipped with tungsten lamps and Holophane shades, making a scientific lighting device, is winning support in every direction.

ELLIOTT BROTHERS, Lewisham, London, England, are distributing pamphlet D-20, devoted to a description of Elliott ammeters, voltmeters and wattmeters for alternating and continuous current, in both portable and switchboard patterns. The agents for the United States are John Bliss & Company, 128 Front street, New York city.

THE NORTHERN ELECTRICAL MANUFACTURING COMPANY, Madison, Wis., in bulletin No. 59, describes the Northern type "S" motors. These are for constant and adjustable speed, and are built either open, semi-enclosed or enclosed, for mill and factory service. Copies of this bulletin will be furnished to those interested upon request.

THE PACIFIC ELECTRIC HEATING COMPANY, Ontario, Cal., in the September issue of "Hot Points," makes a number of very interesting suggestions concerning its flat-irons. It points out to central stations the advisability of inaugurating a flat-iron campaign, and directs attention to the successful work which has been done in other parts of the country.

THE CENTRAL ELECTRIC COMPANY, Chicago, Ill., is distributing several publications on Columbia tungsten and Columbia tantalum-filament lamps, calling attention to the fact that Columbia lamps have been on the market for some nineteen years with unqualified success. Accompanying these publications is a considerable amount of information, showing the watt consumption of the various lamps.

THE AMERICAN BRAKE SHOE AND FOUNDRY COMPANY, Chicago, Ill., has issued a bulletin describing manganese steel castings. These castings enter into the manufacture of jaw crusher parts, gyratory crushers, crushing rolls, stamp mills, screens, clay-mixing machinery, wheels and, in fact, every form of mechanical appliance. The company is also prepared to furnish vanadium, chrome, nickel and chrome-nickel-steel castings.

THE ALLIS-CHALMERS COMPANY, Milwaukee, Wis., announces that the waterworks, electric light and power plant of the city of Austin, Tex., is installing an Allis-Chalmers steam-turbine generator unit. The turbine will increase the efficiency of the plant beyond its rated capacity, besides materially reducing its operating expenses. It is a 500-kilowatt, sixty-cycle, three-phase, 2,300-volt machine, designed to run condensing at a speed of 3,600 revolutions per minute.

THE FORT WAYNE ELECTRIC WORKS, Fort Wayne, Ind., in bulletin No. 1,110, describes standard multiphase switchboard panels. The company has also issued bulletin No. 1,111, devoted to electric motor drives applied to machine tools. This is a very handsome catalogue, and is replete with interesting information on this phase of electrical application. In addition to the descriptive matter there are illustrations of a great many installations which indicate the wide range of utility of Fort Wayne motors.

THE MASSACHUSETTS CHEMICAL COMPANY is building a new addition to its factory at Walpole, Mass., comprising some 15,000 square feet of floor space, to accommodate the tape department, which has entirely outgrown its present quarters. The tapes manufactured by this company, as a result of close attention to the needs of the electrical trade, backed up by patient research work in the laboratory and the co-operation of a well-equipped plant, have been for many years well and favorably known for their high initial and permanent quality.

THE WARD LEONARD COMPANY, Bronxville, N. Y., reports increasing orders for its portable meter-testing rheostats. These rheostats are now in use by the New York Edison Company, Commonwealth Edison Company, of Chicago; Detroit Edison Company, Brooklyn Edison Company and lighting companies in Tucson, Ariz.; Bay City, Mich.; Tyrone, Pa.; Earlville, N. Y.; Vinita, Okla.; Roanoke, Va.; Utica, N. Y.; Ironwood, Mich.; Chattanooga, Tenn.; Kansas City, Mo.; Pensacola, Fla.; Denver, Col.; New Orleans, La., and Decatur, Ill. There are demands from every section of the country, and many have been sold in Canada. Over 600 of these load boxes are now in service.

Directory of Electrical and Allied Engineering and Scientific Societies.

(Published in the Second Issue of Each Month.)

AMERICAN ASSOCIATION OF ELECTRIC MOTOR MANUFACTURERS. Secretary, W. H. Tapley, Walker Electric Company, Twenty-third and Noble streets, Philadelphia, Pa. Next meeting, January, 1909.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. Secretary, L. O. Howard, Cosmos Club, Washington, D. C.

AMERICAN ELECTROCHEMICAL SOCIETY. Secretary, Dr. J. W. Richards, Bethlehem, Pa. Fall meeting, New York city, October 30-31.

AMERICAN ELECTROTHERAPEUTIC ASSOCIATION. Secretary, Dr. Albert C. Geyser, 352 Willis avenue, New York city.

AMERICAN FOUNDRYMEN'S ASSOCIATION. Secretary, Dr. Richard Moldenke, Watchung, N. J.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Secretary, Ralph W. Pope, Engineering Societies Building, 29 West Thirty-ninth street, New York city.

AMERICAN INSTITUTE OF MINING ENGINEERS. Secretary, Rossiter W. Raymond, 29 West Thirty-ninth street, New York city.

AMERICAN MATHEMATICAL SOCIETY. Secretary, F. N. Cole, 50 West 116th street, New York city.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION. Secretary, J. W. Taylor, Old Colony Building, Chicago, Ill.

AMERICAN ROENTGEN RAY SOCIETY. Secretary, Dr. G. C. Johnson, 514 Bijou Building, Pittsburg, Pa. Annual meeting, New York city, December 28-30.

AMERICAN SOCIETY FOR TESTING MATERIALS. Secretary, Professor Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF CIVIL ENGINEERS. Secretary, Charles Warren Hunt, 220 West Fifty-seventh street, New York city.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Secretary, Calvin W. Rice, 29 West Thirty-ninth street, New York city.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS. Secretary, A. P. Folwell, 239 West Thirty-ninth street, New York city. Annual meeting, Atlantic City, N. J., October 20-23.

AMERICAN STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, B. V. Swenson, Engineering Societies Building, 29 West Thirty-ninth street, New York city. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY ACCOUNTANTS' ASSOCIATION. Secretary, Elmer M. White, treasurer Birmingham Railway, Light and Power Company, Birmingham, Ala. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY CLAIM AGENTS' ASSOCIATION. Secretary, B. B. Davis, claim agent Columbus Railway and Light Company, Columbus, Ohio. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY ENGINEERING ASSOCIATION. Secretary, J. W. Corning, electrical engineer Boston Elevated Railway Company, Boston, Mass. Annual convention, Atlantic City, N. J., October 12-16.

AMERICAN STREET AND INTERURBAN RAILWAY MANUFACTURERS' ASSOCIATION. Secretary, George B. Keegan, 2321 Park Row Building, New York city. Annual convention, Atlantic City, N. J., October 12-16.

ARKANSAS ASSOCIATION OF PUBLIC UTILITIES OPERATORS. Secretary, J. E. Cowles, superintendent of lighting, Hot Springs Light and Railway Company, Hot Springs, Ark.

ARKANSAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

ASSOCIATION OF CAR-LIGHTING ENGINEERS. Secretary, G. B. Colegrove, Illinois Central Railroad. First annual meeting, Chicago, Ill., November 18.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES. Secretary, D. L. Huntington, second vice-president and manager Washington Water Power Company, Spokane, Wash.

ASSOCIATION OF ELECTRIC LIGHTING ENGINEERS OF NEW ENGLAND. Secretary, Welles E. Holmes, 308 Washington street, Newton, Mass.

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS. Secretary, P. W. Drew, Wisconsin Central Railway, Milwaukee, Wis.

CALIFORNIA ELECTRIC RAILWAY ASSOCIATION. Secretary, L. E. W. Pioda, Oak and Broderick streets, San Francisco, Cal.

CALIFORNIA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, P. T. Whittier, Spencer, Cal.

CANADIAN ELECTRICAL ASSOCIATION. Secretary, T. S. Young, Toronto, Canada.

CANADIAN STREET RAILWAY ASSOCIATION. Secretary, Acton Burrows, 33 Melinda street, Toronto, Ontario.

CENTRAL ELECTRIC RAILWAY ASSOCIATION. Secretary, W. F. Milholland, secretary and treasurer Indianapolis Traction and Terminal Company, Indianapolis, Ind.

COLORADO ELECTRIC LIGHT, POWER AND RAILWAY ASSOCIATION. Secretary, J. C. Lawler, Colorado Springs, Col.

CONNECTICUT STATE STREET RAILWAY ASSOCIATION. Secretary, F. W. Poole, Bridgeport, Ct.

ELECTRIC CLUB OF CLEVELAND. Secretary, George L. Crosby, 1200 Schofield Building, Cleveland, Ohio.

ELECTRICAL CONTRACTORS' ASSOCIATION OF NEW YORK STATE. Secretary, John P. Faure, 77 Water street, Ossining, N. Y.

ELECTRICAL CONTRACTORS' ASSOCIATION OF STATE OF MISSOURI. Secretary, Charles J. Sutter, 1220 Pine street, St. Louis, Mo.

ELECTRICAL TRADES ASSOCIATION OF CHICAGO. Secretary, Frederic P. Vose, Marquette Building, Chicago.

ELECTRICAL TRADES ASSOCIATION OF PHILADELPHIA. Secretary, E. A. Symmes, 810 Drexel Building, Philadelphia, Pa. Meetings, second and fourth Thursdays of each month.

ELECTRICAL TRADES ASSOCIATION OF CANADA, LIMITED. Secretary, William R. Stanley, Royal Insurance Building, Montreal, Canada.

ELECTRICAL TRADES ASSOCIATION OF THE PACIFIC COAST. Secretary, Albert H. Elliott, Claus Spreckels Building, San Francisco, Cal. Monthly meetings, San Francisco, first Thursday of each month.

ELECTRICAL TRADES SOCIETY OF NEW YORK (Member National Electrical Trades Association). Secretary, Franz Neilson, 80 Wall street, New York city. Board of directors meets second Friday of each month.

EMPIRE STATE GAS AND ELECTRIC ASSOCIATION. Secretary, Charles H. B. Chapin, 154 Nassau street, New York city.

ENGINEERS' CLUB OF PHILADELPHIA. Secretary, H. G. Perring, 1317 Spruce street, Philadelphia, Pa.

ENGINE BUILDERS' ASSOCIATION OF THE UNITED STATES. Secretary, J. I. Lyle, 39 Cortlandt street, New York city.

ILLINOIS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. A. Camp, Henry, Ill.

ILLINOIS STATE ELECTRICAL ASSOCIATION. Secretary, H. E. Chubbuck, La Salle, Ill.

ILLUMINATING ENGINEERING SOCIETY. Secretary, Van Rensselaer Lansingh, Engineering Societies Building, 33 West Thirty-ninth street, New York city.

INDEPENDENT TELEPHONE ASSOCIATION OF TEXAS AND LOUISIANA. Secretary, C. A. Shock, Sherman, Tex.

INDIANA ELECTRIC RAILWAY ASSOCIATION. Secretary, P. H. White, Indianapolis, Ind. Monthly meetings, second Tuesday of each month.

INDIANA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. S. Norton, Indianapolis, Ind.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS. Secretary, Frank P. Foster, Corning, N. Y.

INTERNATIONAL INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. B. Ward, Grand Rapids, Mich. Secretary's office, Monadnock Building, Chicago, Ill.

IOWA ELECTRICAL ASSOCIATION. Secretary, W. N. Keiser, Des Moines, Iowa.

IOWA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, C. C. Deering, Boone, Iowa.

IOWA STREET AND INTERURBAN RAILWAY ASSOCIATION. Secretary, L. D. Mathes, Dubuque, Iowa.

KANSAS GAS, WATER, ELECTRIC LIGHT AND STREET RAILWAY ASSOCIATION. Secretary, James D. Nicholson, Newton, Kan. Annual meeting, Pittsburg, Kan., October 8-10.

KENTUCKY INDEPENDENT TELEPHONE ASSOCIATION. Secretary, W. G. Turpine, Henderson, Ky.

MAINE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, M. E. Crow, Houlton, Me.

MAINE STREET RAILWAY ASSOCIATION. Secretary, E. A. Newman, 471 Congress street, Portland, Me.

MASSACHUSETTS STREET RAILWAY ASSOCIATION. Secretary, Charles S. Clark, 70 Kilby street, Boston, Mass. Meets second Wednesday of each month, except July and August.

MASTER CAR BUILDERS' ASSOCIATION. Secretary, J. W. Taylor, 390 Old Colony Building, Chicago, Ill.

MICHIGAN ELECTRIC ASSOCIATION. Secretary, A. C. Marshall, Port Huron, Mich.

MICHIGAN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, A. A. Burch, Battle Creek, Mich.

MISSOURI ELECTRIC LIGHT, GAS AND STREET RAILWAY ASSOCIATION. Secretary, Claude L. Clary, Sikeston Electric Light and Power Company, Sikeston, Mo.

MISSOURI INDEPENDENT TELEPHONE ASSOCIATION. Secretary, George W. Schweer, Windsor, Mo.

NATIONAL ARM, PIN AND BRACKET ASSOCIATION. Secretary, J. B. Magers, Madison, Ind.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION OF THE UNITED STATES. Secretary, W. H. Morton, 94 Genesee street, Utica, N. Y.

NATIONAL ELECTRICAL TRADES ASSOCIATION. Secretary, Frederic P. Vose, 1343 Marquette Building, Chicago.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Secretary, John F. Gilchrist, Commonwealth Edison Company, Chicago, Ill.

NEBRASKA ELECTRICAL ASSOCIATION. Secretary, William Bradford, Lincoln.

NEBRASKA INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. E. Mattison, Lincoln, Neb.

NEW ENGLAND ELECTRICAL TRADES ASSOCIATION. Secretary, Alton F. Tupper, 60 State street, Boston, Mass.

NEW ENGLAND STREET RAILWAY CLUB. Secretary, John J. Lane, 12 Pearl street, Boston, Mass. Meetings held on fourth Thursday of each month.

NEW YORK ELECTRICAL SOCIETY. Secretary, G. H. Guy, Engineering Societies Building, 29 West Thirty-ninth street, New York city.

NEW YORK STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, R. Max Eaton, Niagara Falls, N. Y.

NORTHWEST ELECTRIC LIGHT AND POWER ASSOCIATION. Temporary secretary, J. D. Crary, Aberdeen, Wash.

NORTHWESTERN ELECTRICAL ASSOCIATION. Secretary, R. N. Kimball, Kenosha, Wis.

OHIO ELECTRIC LIGHT ASSOCIATION. Secretary, D. L. Gaskill, Greenville, Ohio.

OHIO INDEPENDENT TELEPHONE ASSOCIATION. Secretary, O. O. Welsheimer, Columbus, Ohio.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS. Secretary, F. W. Ballard, Cleveland, Ohio.

OHIO STREET RAILWAY ASSOCIATION. Secretary, Charles Currie, Akron, Ohio.

OKLAHOMA ELECTRIC LIGHT, RAILWAY AND GAS ASSOCIATION. Secretary, Galen Crow, Guthrie, Okla.

OLD TIME TELEGRAPHERS' AND HISTORICAL ASSOCIATION. Secretary, Frank J. Scherrer, New York city.

ORDER OF THE REJUVENATED SONS OF JOVE. C. B. Roulet, Mercury, Dallas, Tex. Annual meeting, Buffalo, N. Y., October 15-16.

PACIFIC COAST ELECTRIC TRANSMISSION ASSOCIATION. Secretary, Samuel G. Reed, Portland, Ore.

PENNSYLVANIA ELECTRIC ASSOCIATION. Secretary, E. S. Smith, Towanda.

PENNSYLVANIA STATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, H. E. Bradley, 135 South Second street, Philadelphia.

PENNSYLVANIA STATE STREET RAILWAY ASSOCIATION. Secretary, Charles H. Smith, Lebanon, Pa.

PIKE'S PEAK POLYTECHNIC SOCIETY. Secretary, E. A. Sawyer, Colorado Springs, Col. Meetings, second Saturday of each month.

RAILWAY SIGNAL ASSOCIATION. Secretary, C. C. Rosenberg, Bethlehem, Pa. Annual meeting, Washington, D. C., October 13-15.

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION. Secretary, Arthur L. Williston, Pratt Institute, Brooklyn, N. Y.

SOUTH DAKOTA INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, E. R. Buck, Hudson, S. D.

SOUTHWESTERN ELECTRICAL AND GAS ASSOCIATION. Secretary, J. A. Myler.

STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK. Secretary, J. H. Pardee, J. G. White & Company, New York, N. Y.

TEXAS INDEPENDENT TELEPHONE ASSOCIATION. Secretary, Charles F. Speed, Texarkana, Ark.

UNDERWRITERS' NATIONAL ELECTRIC ASSOCIATION. Secretary Electrical Committee, G. M. Goddard, 55 Kilby street, Boston, Mass.

VERMONT AND NEW HAMPSHIRE INDEPENDENT TELEPHONE ASSOCIATION. Secretary-treasurer, G. W. Buzzell, St. Johnsbury, Vt.

VERMONT ELECTRICAL ASSOCIATION. Secretary, C. C. Wells, Middlebury Electric Light Company, Middlebury, Vt.

VIRGINIA STATE INDEPENDENT TELEPHONE ASSOCIATION Secretary, B. L. Fisher, Rocky Mount, Va.

WESTERN ASSOCIATION OF ELECTRICAL INSPECTORS. Secretary, W. S. Boyd, 382 Ohio street, Chicago, Ill.

WESTERN SOCIETY OF ENGINEERS (Electrical Section). Secretary, J. H. Warder, 1737 Monadnock Block, Chicago, Ill.

WISCONSIN ELECTRIC AND INTERURBAN RAILWAY ASSOCIATION. Secretary, Clement C. Smith, president Columbia Construction Company, Milwaukee, Wis.

WISCONSIN INDEPENDENT TELEPHONE ASSOCIATION. Secretary, J. C. Crowley, Jr., Superior, Wis.

Record of Electrical Patents.

Week of September 29.

899,499. STREET SIGNAL FOR CARS. Newell G. Augir, Brooklyn, N. Y. Filed June 28, 1907. A continuous designation curtain is mounted upon rollers which are actuated at certain points on the line.

899,514. SWITCHBOARD SIGNAL LAMP. Edward B. Craft, Wilmette, Ill., assignor to Western Electric Company, Chicago, Ill. Filed February 1, 1907. The lamp base is entirely separated from the bulb.

899,524. TELEPHONE CUTOFF. Henry S. Gilbert and William F. Drake, Pueblo, Col. Filed October 26, 1907. The transmitter or receiver may be cut out of circuit.

899,535. ELECTRICAL SYSTEM OF DISTRIBUTION. Albert S. Hubbard, Belleville, N. J., assignor to Gould Storage Battery Company, New York. Filed January 29, 1908. The storage battery is connected to one of two independent circuits.

899,564. SELECTIVE SIGNALING SYSTEM. Harry O. Rugh, Sandwich, Ill. Filed December 9, 1907. The time element of the circuit is controllable.

899,578. TROLLEY-POLE CATCHER. John H. Walker, Lexington, Ky. Filed December 26, 1907. The trolley pole is controlled by a ratchet and carrier.

899,588. TRANSPORTATION SYSTEM. William C. Carr, Buffalo, N. Y. Filed September 25, 1906. The position of the car is indicated upon a device at the central station.

899,593. AUTOMATIC THIRD-RAIL CONTACT-SHOE GUARD. William E. Hayes, Frankfort, N. Y. Filed January 22, 1908. The contact shoe is equipped with a traveler arranged in advance of the shoe, and adapted to engage with and be operated by the third rail.

899,598. SOLENOID MOTOR. Lemuel F. Howard, Edgewood Park, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed October 23, 1906. A semaphore arm is operated by the movement of a plunger in a solenoid.

899,613. CABLE DRUM. Alvin A. Pifer, Cleveland, Ohio, assignor to Cleveland Armature Works, Cleveland, Ohio. Filed March 6, 1908. Means are provided for effecting contact between a cable reeled upon a drum and an outside source of power.

899,618. STARTING DEVICE FOR GASOLENE ENGINES. Frank Reynolds, Syracuse, N. Y. Filed February 17, 1904. Contact is made through the medium of levers working on the shaft of the engine.

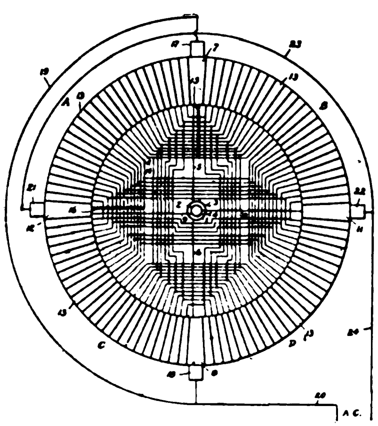
899,629. CONVERTER. Harry Shoemaker, Jersey City, N. J., assignor to International Telegraph Construction Company, New York. Filed December 20, 1906. Means are provided for supplying direct current to a plurality of commutator segments at symmetrical points.

899,634. HIGH-POTENTIAL SPARK-COIL. Chester H. Thordarson, Chicago, Ill. Filed December 23, 1907. The air-gap is formed transversely through the magnetic circuit of a high-potential spark-coil.

899,636. GROUNDING CLAMP FOR ELECTRIC WIRES. Wheeler H. Vibber, New London, Ct., assignor to the Gillette-Vibber Company, New London, Ct. Filed April 20, 1907. The clamp is provided with a yielding stop finger at one end.

899,637. ELECTRIC INSTALLATION MOLDING BOX. Wheeler H. Vibber, New London, Ct., assignor to the Gillette-Vibber Company, New London, Ct. Filed June 11, 1907. The molding box body contains one or more U-shaped parts.

899,638. COMBINED BUSHING AND COUPLING FOR ELECTRIC INSTALLATION. Wheeler H. Vibber, New London, Ct., assignor to the Gillette-Vibber Company, New London, Ct. Filed January 30, 1908. A combination of an elbow having a bushing end formed with an external shoulder and external threads provided with a locknut.



899,629.—CONVERTER.

899,639. BOX CONNECTOR FOR ELECTRIC INSTALLATION. Wheeler H. Vibber, New London, Ct., assignor of one-half to the Gillette-Vibber Company, New London, Ct. Filed June 4, 1908. A combination of a bushing formed with a transverse slot and a yielding binding strap entering said slot.

899,641. PLEASUREPHONE. Charles A. Wardner, Brushton, N. Y. Filed April 19, 1907. Telephonic receivers are connected in multiple to main-line conductors at outlying stations.

899,684. FAN. Otto Seig, New York, N. Y. Filed April 22, 1908. A fan provided with a coned deflector composed of a series of flaring rings set one behind the other, and increasing in diameter from front to rear.

899,708. CONNECTION FOR ELECTRIC CONDUCTORS. Frank H. Ball, North Plainfield, N. J. Filed August 6, 1906. Spring clamps engage the conductor with a spring-pressed contact.

899,717. CONTROLLER REGULATOR. Cyrus P. Ebersole, Keokuk, Iowa, assignor, by mesne assignments, to American Automotoneer Company, Philadelphia, Pa. Filed December 16, 1907. A hood is rotatably mounted in such combination that its movement in one direction is regulated.

899,749. FIRE ALARM. Bernard B. Mears, Baltimore, Md. Filed November 16, 1907. A battery and bell are connected in the fire-alarm circuit.

899,751. IGNITION-CONTROLLING APPARATUS. Charles Mitchell, Jr., Milwaukee, Wis. Filed October 21, 1907. Means are provided for switching the ignition current from one circuit to another.

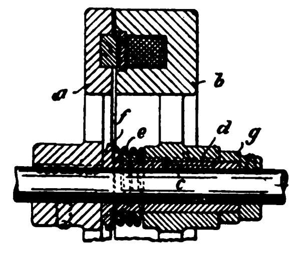
899,770. IGNITION SYSTEM FOR EXPLOSION ENGINES. Richard Varley, Englewood, N. J., assignor to Varley Duplex Magnet Company. Filed November 8, 1907. A continuously rotating shaft makes contact with metallic plungers in different angular planes.

899,773. TROLLEY SWITCH. Benjamin G. Watkins, Nehawka, Neb., assignor of one-third to Julian A. Pollard, Jr., and one-third to Julian A. Pollard, Nehawka, Neb. Filed January 1, 1907. The switch is operated by the passage of the car over an actuating mechanism.

899,787. TELEPHONE SYSTEM. Alfred H. Dyson, Chicago, Ill., assignor to Milo G. Kellogg, Chicago, Ill. Filed February 5, 1906. Means are provided for the transmission of directive currents to selective switches.

899,815. AUSCULTAPHONE. Louis A. Townsend, Fort Dodge, Iowa. Filed May 13, 1907. A combination receiver and transmitter.

899,822. CLUTCH. Heinrich Ast, Vienna, Austria-Hungary, assignor to the firm of Vulkan Maschinenfabriks-Actien-Gesellschaft, Vienna, Austria-Hungary. Filed June 15, 1906. The clutch member is slidably mounted on the running shaft.



899,822.—CLUTCH.

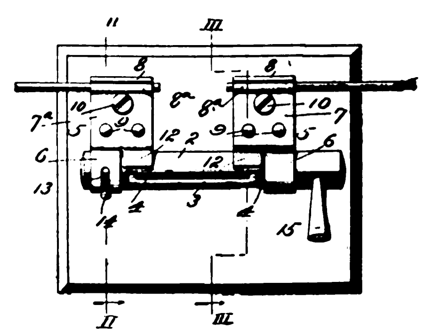
899,823. PRIMARY BATTERY. Wilhelm A. F. Bleeck, Brisbane, Queensland, Australia. Filed March 20, 1908. A primary battery of the double fluid type having a combination of sodium-hydroxide and chromic acid.

899,839. HEATING SYSTEM. Andrew G. Paul, Boston, Mass. Filed May 15, 1900. The thermostatic gauge is operated through the closing of an electric circuit.

899,850. TELEPHONE EXCHANGE APPARATUS. Emil Tanke, Berlin, Germany, assignor to Siemens & Halske A. G. Berlin, Germany. Filed June 17, 1905. Annunciators are controlled by means of single and double-coil relays.

899,858. TROLLEY WIRE HANGER. James Bryan, Pittsburg, and Harry Etheridge, McKeesport, Pa. Filed March 20, 1907. The wire hanger is equipped with a clamping member for engaging with the arch portion of the wire.

899,859. AERIAL TROLLEY SUPPORT. James Bryan, Pittsburg; Harry Etheridge, McKeesport, and Edgar M. Balsinger, Pittsburg, Pa. A combination of a pole, span arm, support and hanger.



900,005.—ELECTRIC SWITCH.

899,983. ADDING MACHINE. William S. Horry, Niagara Falls, N. Y., assignor, by mesne assignments, to Burroughs Adding Machine Company, Detroit, Mich. Filed September 26, 1903. The mechanism is motor driven.

900,005. ELECTRIC SWITCH. Charles W. Wachtel, Jamaica, N. Y. Filed November 23, 1907. The rotary oscillating switch-bar carries a contact strip to engage contact lips on the bearings.

900,006. PUSH BUTTON. Charles W. Wachtel, Jamaica, N. Y. Filed November 23, 1907. The contact lever is provided with an angular portion for making intimate contact with the terminals.

900,035. ELECTRIC MOTOR STARTER. William C. O'Brien, Baltimore, Md., assignor to Monitor Manufacturing Company of Baltimore City, Baltimore, Md. Application filed October 23, 1905. The switch is operated by the progressive movement of a plurality of electromagnets.

ELECTRICAL REVIEW

CONTENTS

THE ELECTRIC LOCOMOTIVE.

The renaissance of invention was never more strongly indicated than to-day in its establishment of modern servants to human need.

The first effort to utilize steam for work in Hero's æolipile has been followed by other varied rotary engines alike in their uselessness, until the recent development of this type under the hardly accurate name of the steam turbine has furnished an engine whose economy of steam, limitations of space occupied, and uniform rotative velocity furnishes a marked change in the development of the steam engine which has otherwise advanced by hairbreadths for nearly two generations.

The automobile furnishes another example of the proverbial instance that progress advances by leaps, for the earliest attempts to apply power to locomotion was by steam carriages, and the pneumatic tire has made all possible.

It is over seventy years since Jacobi under the patronage of the Czar endeavored to make this application of electricity, and nearly twenty years later Dr. Charles G. Page in this country spent $160,000 of the money of the United States Government in making a one-half-horse-power motor.

The electric locomotive has been making history during the last year. Its promoters, in the full appreciation of the importance of the problem of making a machine which must maintain the continuity of the service, have devoted their highest skill, but proceeded conservatively, for there were both novelties to be introduced and precedents to be followed. They have produced machines which bear comparisons with the time-honored steam locomotive, and include many advantageous features which can not be ignored in railway operation.

Quicker changes of speed, either in starting or stopping, and the absence of smoke to obscure signals permits closer train leeway, and therefore enables a more dense train occupancy, which is of great importance, especially at terminals and during rush hours. The absence of reciprocating parts relieves the rails, bridges and roadway of pounding. The consumption of current only when the machine is in operation provides an economy of fuel through the adjustment of the averages at the central power station which coincidently supplies a number of these motors.

One of the early instances of the advantages of the absence of smoke occurred in the case of a tunnel in the Far West where the smoke of one locomotive has been sufficient to asphyxiate the engineers and firemen on a train following.

A powerful spring in this tunnel had been regarded as a nuisance until its waters were conducted down a penstock at one of the portals of the tunnel to a valley at whose base it operated a power station whose current moved the trains through the tunnel.

One of the changes in the electric locomotive in comparison with its steam predecessor is its lower centre of gravity. While this permits higher speed on tangents, it applies lateral components on curves in a different manner, and in place of relying to the same extent on the elevation of the outer rail, the direct radial stresses must be considered.

The one element at this time which retards the adoption of electric locomotives to an extent which would otherwise congest the works of every establishment equipped for their manufacture is the financial one. The expense of abandoning existing locomotive plant is indeed serious, and yet, in a mechanical sense, perhaps no more difficult at one time than another.

The average life of a locomotive is generally taken at twenty years, and yet many of them may be like Mrs. Partington's stockings, which lasted just that time, thanks to the old lady's thrift in knitting on new feet each year and new legs every other year. The dictum of Horace Greeley, relative to the resumption of specie payments, "the way to resume is to resume," may apply to the electric locomotive problem.

Responsible manufacturers can furnish data as to costs of installation and operation, which will challenge such comparison with existing expenditures as to answer any question upon the profitable use of such capital, and under such conditions it is believed that the forthcoming financial market will readily respond.

The change is not necessarily a sudden one, for both types of locomotives can be used on the same track, although during the operation of a few electric locomotives the fixed charges on line plant and on a generating station operating at partial capacity would not permit the economy which would exist with the full utilization of an electric plant.

As to the old locomotives, they would be gradually transferred to other lines and disappear in time as did the horses when electricity was in like manner used for street cars.

THE ELECTRIFICATION OF THE MELBOURNE SUBURBAN RAILWAYS.

Charles Merz, consulting engineer to the Victorian Railways Commission, which is responsible for the management of the state railways of Melbourne, Australia, has presented a report going into the question of the electrification of the Melbourne suburban railway system. The report gives a rather complete résumé of the present experience with electric railroading, and the æsthetic advantages, such as deal with bodily comfort, are conceded. It is with the question of the financial and commercial desirability of the change that the report is principally concerned. It is conceded also that a heavy capital expenditure is necessary, and it is not expected that the reduction in operating expenses will be sufficient to pay the interest charges upon this capital expenditure. The advantage which naturally accrues from the more frequent service possible with electric traction must be capitalized, as the possibility of increased schedule speed is one of the characteristic features of electrical operation, particularly in suburban service. The usual features of electrical operation are enumerated; for example, the utilization of the same termini with increased train movement, and the ability to operate under closer headway and provide denser traffic conditions without enlarging or extending the existing track facilities.

Mr. Merz eliminates the three-phase system for various reasons, and devotes his calculations mainly to an analysis of the advantages and disadvantages of single-phase, alternating-current operation with an overhead system, and a protected third rail operating on direct current at 800 volts.

The possibility of extension of the present system is not very large, and it is estimated that beyond the electrification which will be determined upon at once there will not be any great extension; consequently, the advantages which the single-phase, alternating-current system holds in the event of future extensions do not seem to apply in this case. For the Melbourne system Mr. Merz concludes that the additional cost of train equipment with the single-phase system would balance the extra expenditure on the substations required in direct-current practice. This does not conform exactly to the opinions which have been reached in this country for undertakings which have a good many of the same characteristics. Mr. Merz considers also that as a mechanical structure a protected conductor rail is superior to overhead wires, both as regards simplicity and reliability; that it needs fewer repairs, and the repairs themselves are of a much simpler character. He also contends that the alternating-current equipment which would be required for the Melbourne system would be some fifty per cent heavier than that required with the direct-current system, and the latter would at the same time eliminate a good deal of wear and tear to which the heavier equipments would subject the roadbed and track.

As far as the generation of power is concerned, the report is not so definite. It may be that a portion of the power will be obtained from a water power and irrigation scheme which is now being considered. Then again, a portion of the power may be obtained from a power station to be erected some seventy miles distant, on the Brown Coal Fields. Mr. Merz considers that the initial service would have to be provided for by a steam-driven power station erected in the city of Melbourne. The initial requirements will call for a maximum load of from 32,000 to 35,000 horse-power, and an annual expenditure of some \$500,000. The station would be designed to deliver electrical energy as twenty-five-cycle, three-phase current at 12,000 volts, this being generated by high-speed turbines and delivered through underground cables in the city and overhead lines in the suburban districts.

Mr. Merz presents a summary of the expenses of working with steam and electric traction which shows a saving in operating cost of \$136,335 in favor of electricity. These figures, however, do not allow for interest charges upon the new capital outlay, but it is expected that with so considerable a margin this will not be essentially a point upon which a decision will hinge. It has been pointed out so often that it seems needless reiteration to refer to it again at this time, that, whereas in the earlier investigations looking to the application of electric operation to heavy traction the advantages to be gained by the abolition of nuisances in various forms were given prime consideration, the financial consideration was kept in the background. In the investigations which are being made at the present time the æsthetic advantages are conceded and are made an incident, and not a condition. In actual practice it appears that electrification, although involving a terrific capital expenditure, is bringing about such economy of operation that upon a financial basis alone it will be selected as the means toward the end of better traveling facilities at lower costs and with a higher return upon the investment of capital.

INTRINSIC BRILLIANCY.

Electric lights from their earliest use have been considered essentially a brilliant source of illumination, and this feature has been the one which the general public has accepted as affording their chief claim to superiority. This is far from being the true condition, for unless lamps of high instrinsic brilliancy are shaded so that they do not come within the line of vision unsatisfactory results will follow.

In commercial installations lamps are often left unshaded, the excuse being the increase in luminous efficiency. As an example of unnecessary brilliancy, however, there is the case of a new building given over exclusively to creature comforts—a place of recreation and rest. Included among the various rooms is a sun parlor, sumptuously furnished, and among the luxuries are numerous reclining steamer chairs. But the tired and overworked business man seeking rest after his labors, in this haven, must look directly into clusters of six forty-candle-power clear tungsten lamps! The proprietor takes great pride in these fixtures and explains that he designed them especially so that his guests would be able to enjoy the manufactured sunlight!

That some engineers have understood the importance of the subject is undoubtedly true, but just what was the maximum which could be allowed has undergone a great change, and one for the better.

In Dr. Bell's treatise, "The Art of Illumination," he lays stress upon the importance of the subject, and as a guide to the amount which should be permissible he states: "It is a safe working rule to keep the intrinsic brilliancy of all radiants within the field of vision below five candle-power per square inch; preferably down to half that value."

The above-mentioned work was published in 1902, and since that time practically all of the improvements in the lamps and burners, both gas and electric, have been accompanied by a considerable increase in intrinsic brilliancy; whereas the standards set by illuminating engineers have been continually reduced; so that when the authors of two papers at the recent convention of the Illuminating Engineering Society set a maximum which was only a small fraction of one candle-power, there was general acquiescence.

THE GROWTH OF THE INSULATED-WIRE INDUSTRY.

Under the somewhat misleading heading given above, Mr. Ira W. Henry, in the current issue of the *India Rubber World*, discusses the use of rubber as an insulating covering for electrical conductors. He credits Samuel F. Morse, the inventor of the telegraph, with establishing the first authentic record of the use of rubber as an insulator in covering a cable made in 1842. The telegraph, being the first commercial use to which electricity was applied, called for insulated wire, and continual experiments were made by the Magnetic Telegraph Company looking to a satisfactory insulation for a submarine cable; and in 1843 a cable manufactured by Day was laid across the Hudson River from New York to Fort Lee, N. J. This cable was followed, in 1845, by another rubber-covered cable made by Charles Goodyear for Ezra Cornell.

The manufacturers of insulated wires and cables are now using enormous quantities of the best Para rubber, and the constant increase in the demand for their products has led the more far-sighted to investigate closely the supply from its fountainhead. It is stated that one large corporation found it expedient to send experts to South America to arrange for a constant supply direct from the forests, and it is also stated that large quantities were purchased on the ground at a price that paid the expenses of the trip; but financial complications arose to prevent a continuation of this enterprise.

Various processes have been perfected for the utilization of substitutes for rubber, and for certain installations these substitutes render perfectly satisfactory service. But, like every other industry, there are good substitutes and others which do not serve as substitutes at all.

Navy specifications call for a content of between thirty-nine and forty-four per cent of pure Para rubber in rubber-compound insulation, and the United States Signal Corps, which operates over 2,500 miles of rubber-insulated deep-sea cable in Alaskan territory, and over 1,600 miles of rubber cables in various circuits throughout the Philippine group, specifies a pure Para content of forty per cent. Pure Para rubber in its native state absorbs considerable moisture, and upon being dried by evaporation is oxidized and becomes hard and brittle, being rendered useless as a dielectric; so that, while Para rubber often is very essential as a base, it must have produced within it such chemical change as will render available the whole usefulness of the article. This is done by vulcanizing, which practically is the adding to the rubber of about three per cent of sulphur and heating at a certain temperature for a certain length of time. Over-vulcanizing renders the product hard and brittle, while under-vulcanizing renders it inert and flabby. Therefore, even with a fine Para as a base, the utility of a rubber insulation depends upon its process of manufacturing to make it stand the test of time.

Illuminating Engineering Society—I.

Second Annual Convention Held at Hotel Walton, Philadelphia, Pa., October 5 and 6. Report of First Day's Sessions.

THE second annual convention of the Illuminating Engineering Society was held at the Hotel Walton, Philadelphia, Pa., on Monday and Tuesday, October 5 and 6. This convention was very well attended, and the greatest interest was manifested throughout the entire proceedings. Several hundred illuminating engineers and others interested in the subject listened to the addresses and enjoyed the entertainment features which were coincident with the celebration of the 225th anniversary of the founding of the city of Philadelphia.

The first session was called to order on Monday morning at 10.40 o'clock by George Ross Green, of Philadelphia, chairman of the Committee on Arrangements. Mr. Green introduced William F. Gleason, secretary to the mayor, who, in the absence of Mayor Reyburn, welcomed the convention to the city.

Dr. Louis Bell, president of the association, delivered his annual address. He said that he desired to bring before the convention as a feature the topic of street lighting. It was 200-odd years ago that the first attempts at systematic street lighting were made. The activities of men are so far transferred from day to night at the present time that it becomes absolutely necessary to make provision for those who are traveling about after nightfall, and for the general business that is carried on at night. For this purpose plenty of light is necessary, but this light we have to a rather limited extent in most cities. The fundamental criticism against most attempts at street lighting lies not in the illuminants used, nor in their application, so much as it lies in the improper adjustment of the illumination to the needs of the city. Street lighting has been a growth and an evolution, but, like all growths, it has proceeded to a certain extent along the lines of least resistance. The result is that, looking over a city, particularly an American city, however good the intention of the city government, and however excellent the technical skill of those who furnished the light, much is still left to be desired. The difficulty lies in the fact that we spread out our illumination too thinly, so to speak.

Streets which are largely used during the evening should receive illumination commensurate with their importance. Where the night traffic is light and where passersby are few, such a street needs only light enough to enable the people to go about comfortably. A third class of street, which needs individual treatment, is the merely suburban road. The important thing with such streets is to so distribute the light that the illuminants serve to mark the way and clear the passage for the passersby.

The chief streets in this country as a rule are rather poorly lighted; the secondary streets are not particularly well lighted, and the tertiary streets frequently have only one illuminant in every long block. Dr. Bell thought that the chief streets of a city should be so well lighted that it would be possible to consult a handbook or to read the address on an envelope without having to walk half a block to get under the nearest light. In connection with this matter he stated that the foreign practice, in England and on the Continent, is to provide in the different streets light enough to read a paper by. That is the ordinary standard of illumination which is lived up to in the large foreign centres. In actual amount the lighting in London averages something like a quarter of a foot-candle, as against one-tenth, one-eighth or one-quarter that amount in the ordinary American city. One of the great points of difference between the practice here and in Europe is that diffusing globes are practically in universal use except in the United States, and therefore there is less uniformity here than almost anywhere else.

In the matter of distribution one can not sacrifice too much for the sake of uniformity. It does not take an expert in illumination to see whether a street is badly lighted or not, and it does not consequently take an illuminometer with a measurement in the thousandths foot-candle to find a half-way distance between lamps to show that improvements are necessary. The thing is strictly a practical matter, and should be treated as such.

This brings up the question of the direction of measurement. The customary measurement here is a tacit apology for bad lighting. The customary method is a measurement practically half way between the lamps, with a disc or other measuring instrument held normal to the latter. If one gauges his illumination solely by such readings as this he can be guaranteed a mighty badly lighted street in every case, because the tendency of competition, from whatever source it come, is to secure that minimum at as low a maximum as possible. Some types of illuminants have been specialized for the purpose of giving 0.02 or 0.03 of a candle-foot at some point down the street, where, if the same illuminant was designed not to give a special form of illumination, but to give the best efficiency it was capable of, it would be possible to make it light not only the distant parts of the street, but the whole of the street. Every effort toward economy should be an effort directed to increasing the total flux of light, because, with our modern instruments, there is this to be taken into consideration for street lighting: the intrinsic brilliancy is so high that some diffusion is necessary, and they are all of a character which permits of securing diffusion to get redistribution if it is desired.

Dr. Bell considered lighting of municipalities on a moonlight schedule to be entirely inadequate, and discussed the origin of this scale. He showed that there was no real relation between the diffused illumination from the full moon and that which is secured even when a street is brightly illuminated by artificial illuminants. As far as economy in lighting was concerned it would be better to put out every other light than it is to utilize the light on a regularly reduced moonlight schedule.

In concluding, Dr. Bell said that the next three or four years will work a considerable change. Illuminating engineers should insist on having more light better diffused and more evenly distributed.

There was no discussion on President Bell's address, and the report of the Committee on Nomenclature and Standards, of which Dr. A. C. Humphreys, president of Stevens Institute of Technology, is chairman, was called for. In the absence of Dr. Humphreys the report was presented by Dr. E. P. Hyde.

This report consisted, in the main, of a recapitulation of the work which the committee had done in the direction of establishing a common national and international unit of candle-power. This special work was assigned to a subcommittee, and a report from Dr. E. P. Hyde, secretary of the subcommittee, appears in the Nomenclature Committee report. A joint committee composed of subcommittees of the American Institute of Electrical Engineers, the American Gas Institute and the Illuminating Engineering Society on February 14 adopted a resolution recommending the adoption of a common national candle unit, to be maintained at the United States Bureau of Standards, to be lower than the unit at present maintained at Washington by an amount not less than one per cent nor more than three per cent, the exact value to be agreed upon as the result of an international conference. This resolution has been endorsed by the directors of the American Institute of Electrical Engineers and approved by the council of the Illuminating Engineering Society. It will be presented to the convention of the American Gas Institute, which meets this month. The subcommittee also reported that the Bureau of Standards has entered into negotiations with the foreign laboratories in regard to possible agreement upon an international unit of luminous intensity, and the hope was expressed that final agreement may be reached very shortly.

After the presentation of the report Dr. Hyde said that it would be well if when we were speaking of photometric measurements of gas and electric lamps, or if we were speaking of photometric measurements made in this country or abroad, we could always use the same terms. It is a far cry, however, from a purely academic conception of such a condition to the practical realization of it. Many of the industries in this country have endorsed this movement and are backing it at no little inconvenience and expense to themselves: much credit is due to the Illuminating Engineering Society for taking the initiative in this matter, and credit is also due to the American Institute of Electrical Engineers and the American Gas Institute for the cordial reception which they accorded to the overtures of the Illuminating Engineering Society.

Dr. Bell said that he thought that the outlook was bright for an international standard. He had come in touch with representatives of the various interests abroad and found that they were very sympathetic in both Germany and France.

MONDAY EVENING SESSION.

The session on Monday evening was called to order by Dr. Bell at 8.30 o'clock, and the paper by T. J. Little, Jr., entitled "Modern Gas-Lighting Conveniences," was read.

This paper was devoted principally to descriptions of some of the conveniences which have obtained with modern forms of gas fixtures. The electric-spark ignition system and the pilot gas-flame system of ignition were described, and some of the adaptations of incandescent mantle burners to domestic and industrial uses were enumerated.

Dr. Bell remarked that in his experience it appeared as though ordinary electric systems of ignition for gas lighting got out of order very frequently.

Referring to this, Dr. Clayton H. Sharp asked Mr. Little whether there had been any modern developments or improvements in pneumatic lighters which would prevent this trouble from taking place. As he saw it, the chief reason for the failure of electric gas-lighting systems is due to the lack of insulation somewhere in the circuit, so that it appeared that the problem resolved itself largely into a question of proper insulation against the high electrical tensions which are involved either in the jump-spark ignition or in the make-and-break system. With regard to the pilot lighting system, Dr. Sharp asked whether there was any possibility of danger due to the extinguishing of the pilot light by drafts or air or perhaps by clogging of the pipe. In this manner a stream of gas would issue, and this brings up the question whether where water gas is used there would not be considerable danger.

F. N. Morton asked Mr. Little whether there were any developments in the self-lighting gas mantles. There was another type of igniter which was not mentioned in Mr. Little's paper, namely, the Welsbach pyrophoric alloy, about which he would be pleased to get some information.

Walton Forstall stated that it had been his experience to have the gas escape from the pilot light for about forty-eight hours before he realized it, and there was just a faint odor of gas present.

Fritz Beck described the pneumatic gas lighter, and stated that with the kind of tube now generally used it can be operated successfully on about twenty yards for one light. The number of lights to be supplied by one tube is about six, and the distance diminishes with the number of lights enclosed in one circuit. The tube is about one-sixteenth of an inch in diameter and has the advantage over electric wiring in that it does not need any insulation. There is no danger of fire or of getting out of order through lack of insulation, as is the case with the electric gas igniter. The simplicity of the parts of the pneumatic lighting system will probably induce many people to use it. It really consists of a valve, a tube and a pump, the mechanics of which are pretty generally known and understood. Another advantage of the pneumatic ignition system is that any number of lights may be turned on or off. On a chandelier of six lights it is possible to turn on one after the other or all at once, simply by pulling the line on the push-button or pressing a ball. For the ignition of a great number of lights, however, the electrical ignition is probably the best, because the distance over which the pneumatic ignition can be successfully operated is limited.

It seemed to be the consensus of opinion that the chief cause of failure with electric gas ignition systems was that the system was installed without due regard to the insulation. It is not remarkable that where single cotton insulation is used that the system should fail.

In closing the discussion Mr. Little said that the wiring necessary for an electric ignition system did not require the same restrictions as wiring for electric lights. While the potential may be high, the current carried by the wires is extremely low. Furthermore, in the make-and-break system the same insulation is not required as with the jump-spark system, where a potential of several thousand volts is necessary, depending on the number of burners in circuit. Insulating the wire by a covering is not resorted to, and in some installations the insulation would be of no avail. In these cases the wires are bare and run on insulators. The usual practice is to use a copper wire of about No. 18 Brown & Sharpe gauge. This is covered with double cotton windings, which in turn are covered with a heavy braided jacket. The entire conductor is impregnated with paraffin or some similar insulator. A good deal of the trouble which existed in the early ignition systems was due to the method of construction of the burners. Where a wipe contact was made, sometimes the wire, in wiping over, would stick and not pass back. When this happened the battery would be short-circuited and the system would be expensive to maintain. This trouble has been eliminated by the construction of the modern burners.

Mr. Little said that there was no danger from the escape of gas from an extinguished pilot burner in an ordinary room. The natural ventilation of the room would take care of the escape of gas even if it were closed pretty tightly.

Concerning the self-lighting mantle, it did not appear that one had been developed to such a point as would make it possible to state that it was commercially practical. The action of the heat destroys the pyrophoric element, and up to the present time a satisfactory self-lighting mantle has not been produced. Concerning the pyrophoric alloy invented by Dr. von Welsbach, this is in the experimental stage. It is an interesting alloy, the product of the electrical furnace. It is an alloy of iron and cerium, and has the property of emitting a brilliant stream of sparks on being scratched with a sharp, hard surface.

Dr. A. H. Elliott presented his paper, entitled "The Illuminating Value of Petroleum Oils."

This paper gave the results of a number of tests which had been made upon various forms of burners and several qualities of kerosene oil and kerosene-oil mixtures. The author remarked particularly upon the steadiness and reliability of flat-flame lamps, even when burned with common reservoirs where the level of the oil varies as the lamp burns. It was noted that the rate of consumption and the candle-power are extremely constant. The lamps were calibrated against standard sperm candles, and it was noticed that many lamps used gave nearly twice the candle-power of sperm candles for the same weight of oil, while the round-wick lamps gave fully three times as much.

C. O. Bond stated that in his work, using the oil lamp as a standard and employing the student feed and flat-wick type of burner, up to ten hours' use a very satisfactory light was secured. He hoped that a lamp could be produced so that the conditions during a run of twenty-four hours could be checked. After twenty-four hours he found that there was, in most cases, a rather heavy incrustation of the wick where it had been exposed to the flame. Any oil lamp will be open to two objections: First, that it is a wick feed, and second, that it is surrounded by a glass chimney.

Dr. Hyde asked the author whether the absolute value of the lamp could be depended upon, and also asked whether the Methven screen arrangement could be used without having to recalibrate the outfit. In the photometry of electric lamps it is not uncommon to check up the comparison lamps several times in order to see that they have not changed, and it appeared to him that the wick might be retrimmed and the lamp restandardized at intervals. If it ran perfectly constant for eight or ten hours it seemed worth further consideration as a secondary or working standard in gas photometry.

Dr. Elliott, in closing the discussion, stated that he has used kerosene oil of a gravity as low as forty-five degrees Beaumé, and had obtained within two or three per cent of the same light as he did if he used an oil at fifty degrees Beaumé. He did not intend that the discussion should turn upon a photometric standard; he simply desired to record the reliability and photometric value of the different types of flames, and did not wish to establish any claim for the lamps as a standard. He objected to the use of the Hefner light because, in the first place, it was too small a unit, and unless a very keen photometrist was employed it was difficult to read to one-tenth of a candle. Another objection was its color. With a white light such as a Welsbach candle to test, considerable trouble was caused in matching the two shadows on the disc. The Pentane light, he thought, was too clumsy an instrument, and the expense of maintaining it was entirely too high. With kerosene oil the upkeep could be reduced very materially. He described a five-candle-power lamp which had operated for six and one-half days, being turned off each night, and varying only 0.06 of a candle during the week. The lamp was not even trimmed, but was lighted every day and allowed to burn for seven or eight hours and then blown out at night. The next morning it was turned up and lighted, care being taken not to disturb the crust. As stated before, at the end of a week it had gained 0.06 of a candle. He used a cotton wick in preference to either asbestos or felt.

The paper entitled "Street-Lighting Fixtures—Gas and Electric" was presented by H. Thurston Owens.

This paper discussed very briefly the several forms of gas and electric illuminants which are familiar to-day, and indicated the general engineering trend with regard to the installation of these sources of illumination in retail business districts, wholesale business districts, residence streets, prominent thoroughfares in residence districts, and in outlying districts.

V. R. Lansingh described a scheme of lighting which was employed on the London Bridge, at London, England. This consisted of equipping the ordinary square lamp-post with three transparent panes of glass and one pane of opal glass. This threw a considerable percentage of the light back onto the roadway, illuminating the bridge and keeping the glare out of the boatmen's eyes. The scheme could be adopted in our cities to prevent a waste of light which goes toward vacant lots and toward houses, and makes this form of illumination uncomfortable for persons sitting in front of the buildings.

Dr. Elliott stated that in Toronto reflectors were used which redistributed the light so that up and down the street the illumination was about 300 candles, with practically no illumination going to the houses at the side.

J. E. Woodwell stated that it was important to cut down the intrinsic brilliancy of the light source, and that rather than project the light up and down the street it would be better to place a larger number of units on the street, directing the light more in a downward direction. He called attention to the lighting of the Connecticut Avenue Bridge in Washington, D. C., as a successful example of street lighting. The roadway is fairly uniformly lighted, and the sources are of low intrinsic brilliancy. A strong downward distribution of light is given, and the globes are a dense opal glass, which cuts down the intrinsic brilliancy to a very low value.

The paper entitled "Structural Difficulties in Installation Work" was presented by James R. Strong.

The author considers that the best electrical installation from the point of view of the first-class contractor is that installation which requires the least amount of changing and alteration after completion. Modern electric lighting installations in the better class of buildings are of some form of concealed conduit work, with iron or steel outlet boxes at the fixture locations. Therefore, the electrical equipment is as much a part of the structure of the building as is the plumbing or heating equipment, and any additions or alterations in the conduit work after the completion of the building must, to some degree, cause weakness in walls, floors or plaster. It would seem that in designing the lighting for an office building, the proper method of procedure would be to consider each floor as a whole, bearing in mind the class of tenants likely to occupy an office building in a given locality. If the outlets for general illumination are placed on the centre line of windows and if other outlets are placed around the ceiling a short distance inside the lines of partitions, it would seem as though every possible requirement could be met by simple fixtures, and the outlets need not be capped up. This plan would probably involve a greater number of outlets in the original layout than would be absolutely necessary, but when it is considered that no changes will probably be required, it will be appreciated that the additional first cost would be more than made up in the saving of maintenance in the first few years. The paper also discussed the arrangement of the installation for residence lighting.

Dr. Bell said that he felt that a great fault in most installations was an insufficient number of outlets. These should be allowed not only at various points in a room, but also at the central points.

G. H. Jones stated that the introduction of the modern high-efficiency unit has done more than anything else to make improvements and changes necessary in large office buildings. Heretofore the standard practice was to provide a small amount of light for general illumination and require that each desk should have a portable lamp or drop cord. Where it became necessary to shift the desks and office arrangements it resulted in either tearing up the floor or having drop cords carried all around the room. It is now becoming standard practice to have the general illumination intense enough to make all these extra lamps unnecessary. In laying out office-building lighting he recommended that no wall brackets or wall switches be installed in the interior of the walls; that is, in the walls leading from one office to another. The need for this can be done away with largely by having the wall switches put on the outside walls of the building, and if extra outlets are required they can be put on the baseboard of the outside walls and also the baseboard of the columns.

F. G. McGuire described a system of lighting which was under consideration in a building which has been erected for about ten years. The ceiling has no space back of it through which wires could be fished, and everything must run along the surface of the ceiling. All over this building a large number of drop lights have been used for illuminating purposes, and the general scheme has been to employ a network of molding, from which any number of local drops could be secured. Instead of forming receptacles at the base line, a tube was run around the entire room, which could be tapped into at any point, allowing great flexibility in the securing of side lights.

In closing the discussion, Mr. Strong said that the suggestion that the outlets in office buildings be kept off the outside walls was an excellent one. Briefly, his plan is to place a centre outlet and in addition a row of outlets, say, five feet apart, two feet from the wall, forming a square—if the room is square—around the centre outlet. With such a distance between outlets it would be possible by means of a fixture to reach a piece of furniture or desk placed in any part of the room, and while the first cost might be increased a little, the owner would be better satisfied in the long run if a simple change in fixtures could be made to take the place of tearing down the plaster or cutting holes in a brick partition. Mr. Strong stated that he was opposed to the use of moldings. They are unsightly and are dangerous, and the electrical contractor was getting beyond them.

The paper by F. E. Cady, on "The Relation Between Candle-Power and the Voltage of Different Types of Incandescent Lamps," was presented.

In this paper Dr. Cady holds that one of the more important relations governing incandescent lamps is that between voltage and candle-power. In the early days of poor voltage regulation this was evident even to the unskilled eye. At the present time, while a good system may have voltage changes large enough to have an appreciable effect on the life of lamps, they are generally too small to affect the candle-power to a noticeable extent. The author concludes that his experiments establish the following facts: The exponent for change of candle-power with change of voltage is not a constant, but a function of the watts per mean spherical candle; that this exponent is different for different types of filament, but probably very closely the same for lamps of the same type of filament when operated at the same watts per mean spherical candle; that the value of the exponent decreases as the watts per mean spherical candle decrease.

During the discussion of the paper Dr. Hyde asked whether any curves had been derived for the variation in current as compared with variation in candle-power.

Mr. Cady replied that such tests as he had been able to make indicate that these coefficients change in a very similar manner, although the change was not as marked as in the case of the change of candle-power with change of voltage. The coefficient for the change of candle-power with change of watts is smaller, and in some cases only half as great as the change of candle-power with change of voltage.

Dr. Sharp asked Mr. Cady what the change in efficiency of the filament amounted to practically in the photometry of incandescent lamps; what it amounted to in candle-power.

Mr. Cady replied that so far as he knew there were no data published either by lamp factories or the testing laboratories as to exactly what coefficient was used. He had pointed out in the paper the extreme limits over which the coefficients range.

Dr. Bell stated that in fourteen years he had measured something like 25,000 lamps, and that he could probably throw a little light on the matter by saying that there is no means known under the heavens whereby the errors due to bad sorting can be entirely eliminated.

The meeting was then adjourned until Tuesday morning.

New York Edison Entertainment.

The New York Edison Company tendered an entertainment and smoker to the electrical contractors of New York city, in connection with the New York Electrical Show, in the concert hall of Madison Square Garden on Tuesday evening, October 13. The occasion was enjoyed by about 700 or 800 contractors, and the programme, which was arranged by the United Booking Offices of America, included singing and dancing and instrumental performances of a very high order. From 9 to 11 o'clock the vaudeville arrangements held forth, and during this time cigars and other smokables were distributed with a lavish hand. After the entertainment the company's guests were invited to partake of a buffet supper, which was excellently served and greatly enjoyed. The Edison company is to be congratulated upon the handsome way in which it arranged for the entertainment and comfort of its guests.

Among those seen in the Edison box were: T. E. Murray, John W. Lieb, Jr., Arthur Williams, S. D. Sprong, F. C. Bates, Theodore Beran, Dr. George F. Sever, W. D'A. Ryan, E. B. Latham, Louis J. Auerbacher, W. H. Atkins and George H. Guy. William Marconi was an interested visitor to the Edison box during a portion of the evening.

Chicago Electrical Show.

The fourth annual Electrical Show, Chicago, Ill., to be held in the Coliseum, January 16 to 30, 1909, will surpass anything attempted heretofore, judging from preparations now being made. The beautiful decorations of the 1908 show are being enlarged upon and exhibits of many large companies are being prepared on a plan more comprehensive and attractive than ever, many working power exhibits being an added feature. Weber's band, which rendered the music at the last show, has been re-engaged. All indications point to boost for the electrical industry in general through the medium of this great exhibition.

The 213th Meeting of the American Institute of Electrical Engineers.

The 213th meeting of the American Institute of Electrical Engineers was held in the Engineering Societies Building, New York city, on Friday evening, October 9. President Louis A. Ferguson, of Chicago, Ill., called the meeting to order at 8 o'clock. The secretary announced that at the meeting of the board of directors held that afternoon 112 associate members had been elected. The following associates, upon the recommendation of the board of examiners, were transferred to the grade of membership: Robert Albert Hadfield, Mayfair, W., England; Edward Belden Merrill, Winnipeg, Canada; William Noble Dickinson, Jr., New York city.

The paper of the evening, entitled "High-Potential Underground Transmission," by Peter Junkersfeld and E. O. Schweitzer, of the Commonwealth Edison Company, Chicago, Ill., was presented by Mr. Junkersfeld. This paper, in abridged form, appears elsewhere in this issue.

In opening the discussion President Ferguson said that the subject was interesting not only from a scientific standpoint, but it was of considerable importance commercially because of the possible influence on investment and methods of operation in large power and lighting systems. The increase in value of property in the centre of cities has caused an expansion of the congested areas until, in the interest of public safety, overhead construction is necessarily limited, and we find ourselves facing the problem of placing high-tension transmission lines under ground. The possibilities of the future are so great, and the trend of the times so marked, that it would seem that the subject for discussion was a very fertile one, and it would appear very important that the large operating companies which produce electricity and sell it in bulk should make the matter of underground transmission a subject of further investigation and more serious thought.

Following President Ferguson, a discussion communicated by Charles H. Merz, chief engineer and manager of the Bulk Supply Company, Newcastle-on-Tyne, England, was read by Professor H. E. Clifford. Mr. Merz said that visiting engineers had always been impressed by the development and distribution of electrical energy in large cities of the United States. The fact that a large proportion of the work hitherto installed had been in crowded and congested districts probably explains why a conduit system had been generally adopted in this country. The solid system was preferred and largely in vogue in England, and armored cables are used largely there, and almost exclusively on the Continent of Europe. The extension of underground transmission to outlying and less congested districts will probably result in the merits of these systems of laying transmission cables being considered. For congested districts such as are met with in the centre of all of the large cities, the duct system is often the only practicable system because it is impossible to frequently take up the streets to lay further cables or carry out repairs. Accessibility to the cables is, however, some would say, the only advantage of this system, for when laid in this way the lead of the cables is probably more exposed to deterioration by electrolysis and chemical action than in either of the other two systems referred to above. In the so-called solid system the cable is laid in an earthenware or wooden trough sufficiently large to allow a three-quarters-inch clearance all around the cable, which space is filled with bitumen, pitch or similar substance. The trough is covered with three-inch brick or tile. According to the writer's experience, the solid system, in either earthenware or wooden troughs, is the cheapest of the three systems mentioned. An efficient armored cable costs, laid in the ground, in England, from five per cent to ten per cent more than a lead-covered cable laid on the solid system, but it would seem fair to say that an armored cable which is made and finished in the factory, where proper supervision is possible, should have a longer life than cables laid either on the solid system or drawn into ducts. Experience in the north of England shows that a 20,000-volt underground cable system may be installed with assurance that it will work well. In the counties of Northumberland and Durham there are now nearly 100 miles of such cables in use. The cables are three-core paper cables, lead-covered, and laid on the solid system in earthenware troughs.

H. W. Fisher, chief engineer of the Standard Underground Cable Company, said that the results of such tests as are given by the authors will add to the sum total of existing knowledge as to what voltages cables may be subjected to under working conditions. He thought, however, that under other working conditions it must be admitted that similar tests might have shown quite different results. It is therefore highly desirable that other operating companies make similar tests covering a long period of time. He said that the authors had not specified clearly what they meant by "double working voltage." With grounded neutral the voltage to ground on the 20,000-volt lines would be 11,550 volts. He would ask, therefore, if the voltage applied between conductors and ground is two times 11,500, or 23,100 volts, and that between conductors 40,000 volts. If these are the voltages applied, the test to ground is not sufficient, because in some cases the spark-gap method gave over 25,000 volts. He would suggest two and one-half times the working voltage as a figure that is more in keeping with tests made on other large installations. He took exception to the statement that asphaltum troughs certainly guard against electrolysis. If it were possible to perfectly protect a cable from moisture by asphaltum, electrolysis would not occur, but this is scarcely possible, and at the moist spots the electrolysis is greatly accentuated, causing pit-holes in the lead. He knew of cases where thousands of feet of cable laid in asphalt troughs were destroyed by electrolysis.

Henry Gorden Stott, chief engineer of the Interborough Rapid Transit Company, said that on the Manhattan elevated railway and in the subway system in New York city during the last three years there have been over 350 miles of 11,000-volt cable in service. Tables showing the classification of the troubles on this system indicated a total of seven burnouts, due to various causes, one of which was due to a surge, and one only was felt on the cable of 122 miles. The year that the subway was put into operation the cable troubles had fallen to six, due to the elimination of bad joints and various mechanical troubles. When the subway cables were put into operation the number of faults increased again. Lately, however, there have been very few faults, and in the last two years the number of burnouts amounted to 0.28 per 100 miles of cable. This is a record which is rather reassuring, and is better than is being accomplished with overhead transmission lines. So far as the discussion contributed by Mr. Merz was concerned, Mr. Stott would suggest some precaution in considering this. In the English system power was scattered between comparatively small stations. The American plants operate under entirely different conditions, and in the case of the Interborough Rapid Transit Company it was possible to have 300,000 kilowatts on short-circuit between stations.

Mr. Stott said that the mechanical feature which was going to help out materially in the development of power plants is the induction generator. We could not go on adding indefinitely to the capacity in synchronous machines in one plant, as a point would be reached where the short-circuit current would make it impossible to take care of the automatic apparatus. In the case of a bad short-circuit the time-element relays and reverse-current relays all fall back together, and everything goes out in a large system. With the induction generator, however, the present plant can be added to indefinitely without increasing the short-circuit current.

E. J. Berg stated that he had recently had occasion to carry out some experiments on the system of the Brooklyn Edison Company. It was found that abnormal voltages occurred relatively seldom, perhaps only once a week or once in two weeks.

Wallace S. Clark said that the putting of high-voltage primary on cables for the purposes of tests did not do the cable any good, as it did not show anything and there was no assurance that the cable under test would not burn out the next day or the next hour. Insulation tests are perhaps a little better made periodically, and furthermore, with the present tendency to make paper cables with very light insulation, it is rather difficult to get good results from such tests. He believed, however, that if the same amount of attention was paid to watching for electrolysis, as many burnouts or perhaps more would be saved as in any other way.

Alex Dow stated that thirty miles of rubber-covered cables which he had put down in Detroit in 1892 were, to all intents and purposes, as good six months ago as they were the day they were put in. In Detroit the Edison company has two cables operating regularly at 23,000 volts. Each is substantially seven and one-half miles long. The cable conductor is nineteen-strand, equal to No. 2 Brown & Sharpe gauge. The cable is insulated with two-thirty-seconds-inch rubber and six-thirty-seconds-inch varnished cambric on each conductor, and three-thirty-seconds-inch varnished cambric over all, with a three-thirty-seconds-inch lead sheathing. The lead sheath is sectionalized at every second manhole between 700 and 800 feet, and a strip of the lead is removed and insulating rubber substituted in order to prevent the continual travel along the lead sheath of street railway return current. At each of these 700 or 800-foot spaces the lead is solidly connected to earth by copper ground wire. One of these cables has been in continuous service for thirteen months. It is not the older of the two cables, but it has the most continuous and useful history. It went into service on September 4, 1907, and since that time has broken down six times. One of these breakdowns was due to high temperature from a steam-heating pipe in the vicinity, and the other five are not attributable to any known cause. Four breaks were in the cable itself and two were in the joints. There were four breaks to earth and one between phases. Adding this experience to the experience with the second cable, which was actually the first cable in service, the total breakdowns are twelve, seven of which were in the joints and five in the cable. The most notable observation is that the faults that are attributable to nothing but extraordinarily high pressure seem to occur in the middle third of the cable, and are not accompanied by any particularly notable disturbances at the terminals. This seems to confirm the observation made by the authors of the paper of the finding that these disturbances do not travel the entire length of the cable, but may spend their energy in one part thereof.

Warren Partridge said that the experience of the Public Service Corporation of New Jersey with high-potential underground transmission, when reduced to burnouts per mile of cable per year, had been considerably better than the 20,000-volt experience in Chicago, as reported in the paper. When compared with the 9,000-volt system in Chicago, however, the results have been very much worse. In spite of the difficulties experienced on their system, however, it could be agreed with the authors that cable systems are fully as reliable as other elements in an electric power system.

E. E. F. Creighton said that the work presented by the authors was most valuable. If one may look into the future, it seems safe to predict that engineers of power transmission systems will some day study the conditions of service as carefully and conscientiously as the insulation is studied on a marine telegraph cable.

L. T. Robinson stated that the reference to the limitations of the oscillograph which was used was not entirely justified. As far as concerns the free periodicity of the vibrators, it is quite possible to produce moving systems in which the current passes through the strips having a frequency nearly double that which was used, or, roughly, 10,000. This is accomplished, however, at such a sacrifice of strength and size of the moving parts that it is not desirable for industrial use. In reference to the statement that the vibrators can not be made absolutely dead-beat, he thought that this must be due to a misunderstanding of what can be accomplished.

Henry Floy stated that, as far as the alternating-current, high-tension cables were concerned, the manufacturing companies were ahead of the operating conditions—that is to say, the manufacturing companies have for years been ready to furnish high-tension cables. He had recently secured figures as to the commercial financial practicability of using high-tension cables. Where conductors are intended to be used on 50,000-volt service it would appear that the thickness of insulation would become so great that three-conductor cable would be impossible, as the leading machines at present available would not be capable of producing a lead sheathing for the cable. The average price for three single-conductor cables is about $4.40 per running foot.

John W. Lieb, Jr., stated that about 1882 a fairly extensive underground system was laid in Milan, Italy, with Edison tubes. It took only about six months in that particular locality to destroy an iron tube under ground. Some time in 1887 or 1888 a line some three or four miles in length, operating on 2,000 volts alternating current, was laid under ground. This was laid with iron-banded armored lead-covered cable, and with this cable was had probably the first experience in operating alternators direct-driven and coupled in parallel. The cable has been in operation ever since, and except for the early troubles, which were due to mechanical defects in the switches and generators, this type of construction has given great satisfaction.

Mr. Lieb read a communication from Philip Torchio, of the New York Edison Company, which described some of the experiences with the New York Edison service. Since June 10, a year ago, there were twelve disturbances on the system, and of these twelve disturbances at least four were indicated by a selective ground detector located on the feeder where the lowering of resistance was going on before the ground indicator gave an indication.

Dr. C. P. Steinmetz said it was extremely satisfactory to discover that underground cable systems can be operated even when on enormous magnitude and with enormous power back of them, with high safety and a small proportion of breakdowns. It would be interesting to investigate and calculate how much stored energy there is available in the system the authors describe.

In closing the discussion, Mr. Schweitzer said that, with regard to the question of the meaning of 100 per cent above normal voltage, this had reference to 100 per cent above normal pressure of any phase to ground, and where the paper referred to 200 per cent rise in current, that meant 100 per cent above the normal full-load current.

The meeting was then adjourned.

Electric Cooking for Restaurants.

An article in *Electrical Engineering* (London), September 17, describes the results of some experiments conducted in a London restaurant with electrical cooking apparatus. The apparatus consists of an oven, a large grill measuring fifteen inches by ten inches and consuming 1,800 watts when hot; an egg poacher six and one-half inches in diameter, consuming 600 watts; a toaster, and a six-and-one-quarter-inch hot plate. The most interesting piece of apparatus is the large grill. This is constructed as follows: Under the nickel-plated cover is a pad of asbestos wool some two inches thick, beneath which is a metal reflector. A grid of spirally wound resistance wire is supported from the latter on small porcelain buttons, and the heat is reflected down onto the chop or steak placed on the grid below. A five-gallon copper boiler is used to keep water at the boiling point. This consumes 1,000 watts. A test made for eight days, during which time the plant was in use almost continuously from twelve noon to 9 P. M. daily, showed that the average consumption of the oven, which had been in use only for keeping the plates hot, was eight and three-quarter units per day; that of the egg poacher, five and one-eighth units; of the grill for chops and steaks, thirteen and one-half units, and of the small grill for toasting bread, eleven and three-quarter units. The total consumption was 313 units, making an average daily consumption of thirty-nine and one-eighth units, which, at 1.8 pence per unit makes a daily cost of three shillings eight pence for current, or about eighteen cents per day, or two cents per hour for each grill, boiling plate and oven in use. The large grill, which is capable of cooking twelve chops or steaks at one time, cooked 678 pieces of meat, at a cost for current of three-eighths of a cent per chop or steak.

STREET RAILWAY CONVENTIONS.

MEETINGS OF THE AMERICAN STREET AND INTERURBAN RAILWAY ASSOCIATION AND ITS AFFILIATED ORGANIZATIONS AT ATLANTIC CITY, N. J., OCTOBER 12 TO 16.

The annual series of conventions of the American Street and Interurban Railway Association and its affiliated organizations was opened at Atlantic City, N. J., Monday afternoon, October 12, with a meeting of the Transportation and Traffic Association. President C. Loomis Allen, of Utica, N. Y., called the meeting to order at 3 o'clock and delivered his annual address. He said that it was a cause for regret that the congratulatory remarks from the Hon. W. Caryl Ely would have to be deferred until the next day.

The work of the American Street and Interurban Railway Association will, in the future, undoubtedly be confined very largely to questions of policy and public relations, including national, state and municipal governments, and to such other matters as only the chief executive officers would be interested in.

Mr. Allen discussed the work of the Accountants', the Engineering and the Claim Agents' associations. The Transportation and Traffic Association, he said, has a much larger field of work, and it will require in the future the expenditure of more energy, more time and more money if the greatest results from this fertile field are to be produced. The Claim Agents, Accountants and Engineers, to a large extent, are consumers of gross earnings. The Transportation and Traffic men are primarily the producers of gross earnings. Since the organization meeting it has been a pleasure to devote considerable time to the work of this association.

Mr. Allen is convinced that the best results will be produced by committee work. It is not intended that committee work shall be confined to a meeting of the committee once or twice during the year, but by committee work is meant the study and knowledge of conditions existing in the various properties of the member companies, the reduction of these conditions to a fair statement in writing, the remedy which should be applied to reconcile abnormal conditions, in so far as is practicable, and the recommendation by the committee of a practical application that will meet transportation and traffic conditions, and perfect street railway service for its patrons, with all that that perfection may mean.

President Allen's address was greeted with enthusiasm, and the secretary read the report of the organization meeting.

The president called for a vote on this report, and stated that if there were no recommendations or exceptions, it would be received and printed in the official proceedings.

John I. Beggs, of Milwaukee, Wis., took some exceptions to several points in the constitution, particularly as regards the matter of eligibility for voting. The paragraph to which Mr. Beggs took objection read: "Each active member shall be entitled to one vote on all questions coming before this association, which shall be cast by a properly accredited representative of its transportation or traffic department." The point was raised that it might not be convenient at all times to have in attendance a representative of the traffic department. In this case there would be no opportunity for a duly accredited officer of the company not a representative of the traffic department to cast the vote for his company.

Mr. Allen said that the points which had been raised by Mr. Beggs should receive careful and serious consideration, and it was finally decided to refer the portions of the constitution and by-laws under discussion back to the committee, with a request that they be given consideration and a further report made.

The report of the executive committee was presented by the secretary. This was accepted, and will be published in the proceedings.

The report of Secretary Swenson covering the period to September 30, 1908, was presented. This report was accepted.

The paper entitled "How Can a Small Road Best Promote Traffic and Increase Its Revenue?" by Ernest Gonzenbach, general manager of the Sheboygan Light, Power and Railway Company, Sheboygan, Wis., was read by J. H. Pardee. This paper was discussed by Messrs. Sylvester, Hegarty, Passailaigue, Gossler, Davis, Pardee, Allen, Dozier, Beggs and Parker.

The meeting was then adjourned to reconvene the next morning.

The Transportation and Traffic Association held further meetings on Tuesday, Wednesday and Thursday. The meetings of the American Association were held on Tuesday afternoon and Wednesday and Thursday afternoons. The meetings of the Engineering Association were held on Tuesday, Wednesday and Friday afternoons and Wednesday morning. The meetings of the Claim Agents' Association were held on Monday and Tuesday afternoons and on Tuesday and Wednesday mornings. The Manufacturers' exhibit was particularly comprehensive and covered the entire expanse of Young's million-dollar pier.

CHILE HYDROELECTRIC PLANT ON THE RIO LOA.

BY FRANK KOESTER.

For the extraction of saltpetre a hydroelectric plant has been installed some eleven miles north of Rica Aventura, utilizing the water of the Rio Loa in the northwestern part of Chile, South America. In this vicinity the saltpetre is found under a layer of gypsum about ten feet thick. The saltpetre is extracted by dynamiting, then transported to the "Oficinas" where it is treated for commercial use.

Prior to the present hydroelectric installation there was a steam-operated plant in connection with which is a 2,000-volt transmission line. Owing to the high cost of the transportation of coal, it proved a poor financial proposition. The steam plant is now used as a reserve.

For utilizing the water of the Rio Loa a comparatively small dam only had to be built across the river. The power plant is located a short distance down stream, as seen in Fig. 1, and has a head varying from eighty-two to 102 feet. It has been designed to accommodate four units, three of which are at present installed, each having a capacity of 455 horse-power at 5,000 volts.

It will be noticed in the accompanying illustration that the complete machinery and also the switchboard were installed before the erection of the superstructure. This was done under the certainty that there would be no rain during that season of the year.

The substructure is made up of rough-faced stone while the superstructure is of a wooden-frame skeleton and brick, the interior being cement plastered, while the floor is tiled. The switchboard itself is located on a raised platform, while the switch gear is housed in a two-story wing. The generating room is served by a hand-operated traveling crane.

The turbines are the inward-flow Francis type and are connected by means of an isolated flexible coupling to a three-phase generator. Between the coupling and turbine is a heavy flywheel to take up fluctuations caused by the cutting of

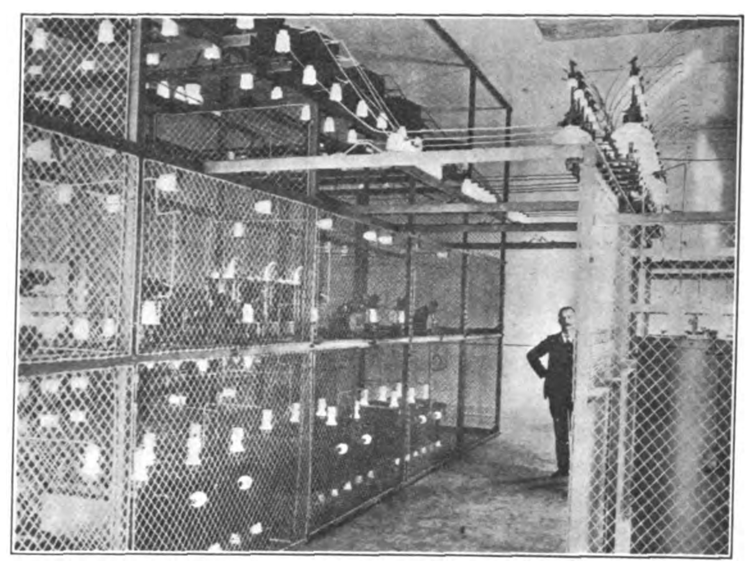

FIG. 4.—HIGH-TENSION SWITCHING COMPARTMENT, HYDROELECTRIC PLANT ON RIVER LOA, NEAR AVENTURA, CHILE.

motors in and out in the various "Oficinas."

Each generator unit has its own exciter mounted on the overhang of the shaft. The generator leads run through trenches to the switchboard. The latter is of ornamental-iron design faced with white marble slabs, there being four panels. In front of the switchboard are five instrument columns, one for each generator unit, and one master control.

The power is distributed by a 20,000-volt transmission line a distance of thirteen miles to the substations at Rica Aventura, Grutas and Empresa, while a fourth substation at Prosperidad is now under construction.

The first section of the conductor is twenty-five square millimetres, the remaining section is sixteen square millimetres. They are carried on wooden poles of a rectangular cross-section.

The line is well protected by lightning arresters and automatic circuit-breakers, the latter being electrically controlled. The lightning arresters consist of a series of horn-gaps, Fig. 4, choke-coils, fluid rheostats and water flow grounds.

The plant was designed and constructed by the Siemens-Schukert Werke, Berlin, who also furnished the above-mentioned steam-power plant.

FINANCIAL REPORTS OF ELECTRICAL COMPANIES.

INTERNATIONAL RAILWAY OF BUFFALO.

The International Railway Company, of Buffalo, N. Y., reports to the Public Service Commission at Albany, for the year ended June 30, 1908, as follows: Gross operating revenue, $4,702,850; operating expenses, $2,751,335; net operating revenue, $1,951,515; taxes, $244,682; operating income, $1,706,833; non-operating income, $26,065; total income, $1,732,898; fixed charges, $894,397; net corporate income, $838,501.

KANSAS CITY RAILWAY AND LIGHT.

The Kansas City (Mo.) Railway and Light Company's report for August and three months, June 1 to August 31, is as follows: August gross, $537,499; expenses, $306,609; August net, $230,890; taxes and interest, $155,540; August surplus, $75,350, comparing with $104,505 for the same month last year. Three months' gross, $1,576,542; expenses, $922,-907; three months' net, $653,735; taxes and interest, $465,349; three months' surplus, $188,386, as against $279,151 for the corresponding quarter of 1907.

PORTO RICO RAILWAYS COMPANY.

The report of the Porto Rico Railways Company for the month of August is as follows: August gross, $35,427; expenses, $21,385; August net, $14,042, as compared with $12,760 for August of last year.

Allis-Chalmers Company Issues Favorable Report.

In the annual report of the Allis-Chalmers Company, which was made public last week, President W. H. Whiteside shows that the operating profits for the year ended June 30, 1908, amounted to $2,573,961, or more than double those of 1907. At the same time there was a surplus after all charges of $385,997, comparing with a deficit last year of $229,817. In his remarks to stockholders President Whiteside says:

"Noteworthy success has been obtained in the sale and operation of our new lines of production, namely, gas engines, steam turbines, hydraulic turbines and electrical apparatus, which are now among the standard products of our company. The extended use of these lines of production, often in connection with our older products, not only by purchasers who have long been our regular customers, but by numerous new customers in almost all classes of industry, forms the basis for an increasing and profitable business."

The detailed income account for the year, with comparisons, follows:

	1908.	1907.
Profit on operation....	$2,573,961	$1,226,242
Maintenance, depreciation, interest, etc...	1,958,147	1,613,540
Net profit for year...	$615,814	*$387,298
Previous profit and loss deficit.........	229,817	†157,481
Surplus.....	$385,997	*$229,817

* Deficit. † Surplus.

The item, profits on operation, as above, is after deducting expenses of manufacturing and selling; dividends on preferred stock of the Bullock Manufacturing Company and ordinary provision for doubtful accounts.

The surplus profits for the year, $615,-814, as above, are equal to 3.81 per cent earned on the $16,150,000 preferred stock.

The report adds: "Inasmuch as owing to present financial conditions there may possibly be a shrinkage in the collection of certain bills receivable, it has been deemed advisable to set aside out of profits a special reserve of $60,000 shown above. Beginning with the second quarter and continuing for half the company's fiscal year, owing to the severe contraction in general business throughout the country the volume of the company's sales averaged about one-half of normal. During the last quarter there was a gradual and steady increase in orders booked."

The balance sheet shows reductions in the inventories amounting to $2,518,841; increase in notes and accounts receivable of $272,137; increase in cash of $1,059,-300, and decrease in accounts and notes payable amounting to the substantial sum of $2,304,413. These changes, together with the net profit on the operations of the year not used for additions to plant and equipment, considerably strengthen the position of the company and increase its working capital.

American Electrochemical Society.

A meeting of the American Electrochemical Society will be held in New York city, October 29, 30 and 31. Headquarters for registration and information will be established on Thursday evening, October 29, at the Hotel Cumberland, Fifty-fourth street and Broadway. On Friday morning and afternoon headquarters will be established in the Chemistry Building of the College of the City of New York. On Saturday, October 31, the meetings will be held at the Chemists' Club. The following programme has been announced:

Thursday, October 29, at 8 P. M., meeting of the board of directors at the Chemists' Club.

Friday, October 30, at 9 A. M., meeting at the Doremus Lecture Theatre, Chemistry Building, College of the City of New York, for reading and discussion of papers; 12.30 P. M., luncheon, by invitation of the staff of the department of chemistry, College of the City of New York, Alumni Hall, main building; 2 P. M., session for the reading of papers, at the College of the City of New York; 7.30 P. M., informal subscription dinner—details to be announced later.

Saturday, October 31, at 9 A. M., session for reading of papers and discussion, at the Chemists' Club; 1 P. M., luncheon at the Hotel Cumberland; 2 P. M., inspection trip—to be announced later; 8.30 P. M., smoker at the Chemists' Club.

Electrical Engineer, Technologic Branch, United States Geological Survey.

The United States Civil Service Commission, Washington, D. C., announces an examination on November 9 to secure list of eligibles from which to make certification to fill a vacancy in the position of electrical engineer in the technologic branch of the United States Geological Survey, at a salary ranging from $1,620 to $3,000 per annum, according to the rating received; and vacancies requiring similar qualifications as they may occur. Applicants should at once apply to the United States Civil Service Commission, Washington, D. C., for application form 304 and special form.

HIGH-POTENTIAL UNDERGROUND TRANSMISSION.[1]

BY P. JUNKERSFELD AND E. O. SCHWEITZER.

From present indications systems operating at potentials of 100,000 volts and over will not be uncommon in a few years, and none dare prophesy what further increase the future has in store.

Within the confines of the largest cities the conditions are sometimes such that it is not advisable to carry these high potentials overhead. In such cases it may be necessary to place the conductors underground. The limitations of insulation and size have kept the transmission voltage for underground cables at about one-third that of overhead transmission, and while there has been a considerable advance in the art the approximate ratio of 1 to 3 seems still to be maintained. However, in large systems of underground transmission, insulation and size are not the only cable limitations. The line-constants may become such that the cable is frequently subjected to dangerously high potentials.

This paper will not deal with experience at pressures lower than 5,000 volts. A typical system using high-potential underground transmission extensively is that of the Commonwealth Edison Company, of Chicago, and its experience will be cited principally. Suffice it to say that at present (September, 1908) the system consists of two generating stations (a third is in process of erection) with a maximum capacity of about 18,000 kilowatts and 100,000 kilowatts, respectively, sixty-six 9,000-volt, three-phase transmission lines aggregating 272 miles, supplying forty-four substations containing synchronous converting equipment almost exclusively. Three additional substations and sixty-eight miles of additional 9,000-volt cable are now under construction.

There is also a 20,000-volt line eleven miles long connected to the 9,000-volt system through step-up transformers and feeding railway and frequency-changer substations located in an outer or suburban zone. Forty-four miles of additional 20,000-volt underground lines are under construction, which will bring the total up to fifty-five miles. The entire cable system is shown in Fig. 1. This 20,000-volt system will be permanently supplied from 5,000-kilowatt, three-phase, step-up transformers connected delta to star with the neutral grounded. The standard size of 20,000-volt cable is 00, and of 9,000-volt cable 0000 and 250,000 circular mils.

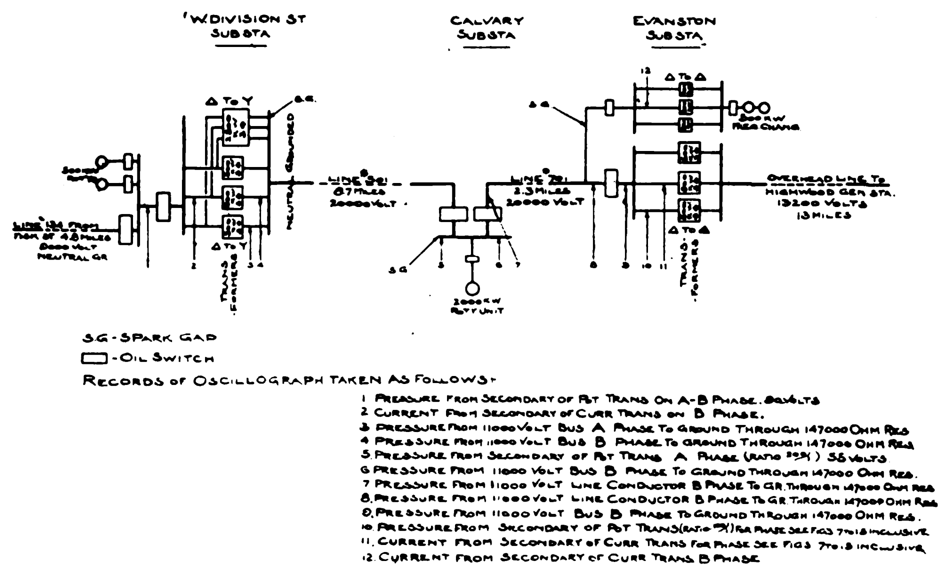

FIG. 1.—SUBSTATION CONNECTIONS OF 20,000-VOLT LINE, SHOWING POINTS AT WHICH OSCILLOGRAMS WERE OBTAINED.

In February, 1902, the twenty-five-cycle, three-phase system of about seventeen miles of three-conductor cable and seven synchronous converter substations was raised from 4,500 to 9,000 volts, the equipment and cable having been installed with this change in view. This transmission system was first put into service in August, 1897. The greater part of the cable at the time of the change to 9,000 volts was 00, some 0 and about one-fifth of 0000 size. The insulation on the original 4,500-volt cables consisted of five-thirty-seconds-inch inner wall of paper around each conductor and an outer wall of three-thirty-seconds inch thick surrounding all three. The thickness of the lead sheath was one-eighth inch. In the 9,000-volt cable the thickness of the paper insulation was finally standardized at six-thirty-seconds inch and four-thirty-seconds inch, respectively.

The early experience in Chicago and elsewhere showed the necessity for avoiding sharp bends and for using extreme care in making the splices. A small number of burn-outs occurred during the first year's operation at 9,000 volts, and nearly all were due to sharp bends or to moisture at the joints. In order to determine how quickly moisture in a cable causes a breakdown, after it has entered through an opening in the sheath, in 1903 Mr. Burch,[1] of Minneapolis, made some interesting experiments. He found that it usually requires from a day to a week for the moisture to work down sufficiently to cause a burn-out. Paraffin had, up to this time, been used at the joints and in the terminal bells, but being hygroscopic in effect, due to voids left after cooling, it was not satisfactory at the higher voltage. About this time some of the engineers of the company, after considerable study and experimentation, developed a high-grade insulating compound which since then has been used exclusively on all high-potential work.

The splices are made up with great care and the compound is poured into the sleeve at a temperature of 150 degrees centigrade in a manner to exclude all moisture. The success of this work is evidenced by the fact that there have been but two failures in splices during the last five and one-half years and there are now some 3,400 splices in the high-tension system. The compound-filled terminal bells were formerly made of brass cylinders with a cast-brass base, a substantial ground connection being made at the base. On some recent work a few bells made of a special impregnated concrete have been used with very satisfactory results. The proper protection of cables against damage due to burn-outs of adjacent cable has received considerable attention, and all cables in manholes are covered with split vitrified-clay tile cemented in. Entirely separate duct lines, either on different streets or on opposite sides of the same street, are provided so as to divide the energy along different routes when possible, so that all important substations have at least two lines, each of which follows a different conduit route.

Semi-annual potential tests were made at the beginning but were discontinued

[1] A paper presented at the 230th meeting of the American Institute of Electrical Engineers, New York, October 9. Abridged.

[1] Burch, A. I. E. E. Trans. 1903, page 433.

when the system became more extensive. The danger and liability of accident from these frequent high-potential tests were thought to more than offset the doubtful advantages derived. Since then testing has been limited to new, altered or repaired cable which, before being put into service, is subjected to a test of double working voltage for one minute.

The record of cable trouble for the last five and one-half years' operation shows that failure of cables thus far has really not been a very serious matter. The line-protecting devices are now so perfected that a cable burn-out causes little disturbance. Of the total of forty-four cases recorded only four seriously disturbed the system, and each one of these was aggravated by faults in the protective relays.

On the 20,000-volt line in Chicago, which has now been in service about fifteen months and which was an initial installation at this higher pressure, there have thus far been a total of four burnouts, one of which was due to a mechanical injury, one to moisture in a poorly made joint, and two were in the cable itself.

It will be seen, therefore, that the experience with high-potential cable has not been such as to cause alarm. The most frequent sources of trouble are from without, and of these electrolysis is apparently the most persistent. However, with rapidly growing systems the destructive effect and danger of breakdowns tend constantly to increase, and it becomes advisable to forego complacency for a while and to look into the system with inquisitive eyes to see just what is going on.

It was this desire to know more about possible dangerous potential rises so that proper safeguards against them could be provided, if found necessary, that led the Commonwealth Edison Company to undertake a series of spark-gap and oscillograph investigations, the principal results of which thus far obtained are described in this paper. A further purpose of the tests was to obtain information regarding these high-voltage systems for use in their further development. The investment required for such 20,000-volt and higher transmission-cable system is very large; it, therefore, becomes all the more imperative to know that such investment is a safe one commercially.

About a year ago a series of oscillograph tests was started on the 9,000-volt system to determine whether or not resonance existed in any part of it, or if dangerous potential rises occurred from any other cause. The oscillograms obtained were taken at the Fisk street station and included current and pressure waves for all principal switching operations, as well as several for a special cable connection in which resonance was sought. None of the records showed any appreciable excess voltage.

These investigations were later continued and expanded but no dangerous rises were found. Spark-gaps were installed at four different points of the system and their record carefully kept. The gaps consisted of needle points in series with which are resistance and fuse. They were connected between each phase and ground. These spark-gaps showed that there are frequent rises of about seventy per cent and occasionally ones of about 100 per cent which apparently have no connection whatever with any switching. These occurred at the station and also in remote substations. At times of cable breakdown, one or more of the spark-gaps invariably discharged at double potential.[1] With grounded systems cables break down first between a phase conductor and ground. When the protective devices fail to act properly, as they did occasionally before recent improvements were made,[2] the arc continues until it is communicated to one or both of the other phases. The effect on the system is then far more severe. Such occurrences were, however, the exception rather than the rule. When, during a breakdown, one or two of the spark-gaps discharge it is on the phase or phases other than the one on which the burn-out occurs. Sometimes all three of the gaps discharge during cable trouble, but not simultaneously. It is quite probable that the potential rises evidenced by these discharges are due to magnetic effect in the generators as much as to surges in the cables. There was only one case of cable breakdown which seemed clearly the result of a surge. During some arrangements which were being made at the Fisk street station to put a potential test on a bus-bar, one of the test leads accidentally came in contact with a live switch stud, the door over which had been opened. This grounded one phase of the system through fifty feet of heavily insulated No. 12 wire in series with the high-tension coil of a dead 150-kilowatt testing transformer. The heavy insulation was punctured in a number of places and the entire fifty feet of test conductor was vaporized. No other damage was done in the station. A few seconds later one of the cables burned out at a point about one mile from the station.

The net result of this investigation indicates that at the present time the 9,000-volt system is reasonably free from dangerous conditions as far as destructive potential rises are concerned. It also indicates the advisability of continuing to make tests on newly installed or repaired cable at double potential for one minute.

Attention was then turned to the new 20,000-volt line in the attempt to learn what difficulties are to be met with there. On the diagram of this line in Fig. 1 are shown the locations at which current and pressure connections were made for the oscillograph. The numerals on the oscillograph refer to the corresponding ones of Fig. 1. Spark-gaps were connected to ground at points marked s.g. These spark-gaps were first installed in the Evanston substation at the end of the line and originally set at 1.1 inch, corresponding to 21,700 volts. During fifteen days A phase discharged eight times, B phase five times, and C phase six times. Five times during this period two gaps discharged at the same time (four on B and C and one on A and B). All other discharges were on one phase at a time. On only one day were there more than one discharge per phase, and on that day B and C phase gaps discharged together twice, the interval between the discharges being eighteen minutes. With the exception of a single discharge on A phase, none of the discharges could be connected with any switching or other apparent source of disturbance. In this single case a heavy lightning storm passed over the overhead transmission line which is fed through transformers from the 20,000-volt line. It seems probable that a static charge passed from the line into the transformer and caused the rise which discharged on the A phase gap. Fourteen days' experience with a gap of 1.15 inch (22,500 volts) showed seven discharges on A phase, six on B, and five on C. The only coincident disturbances were as follows: one discharge on A phase when a steam-driven generator at the Highwood station was "synchronized"; B and C phases discharged together when a steam-driven unit in parallel with generator or frequency changer in Evanston governed poorly causing heavy cross-currents; one discharge on A phase when a steam-driven unit was disconnected at Highwood, and one discharge on B phase when steam-driven unit was shut down in Evanston. With the setting increased to 1.2 inches

[1] Double potential when units with no neutral resistance were grounded and about 130 per cent over potential when neutral was grounded through resistance (R = 2.6 ohms).

[2] June paper A. I. E. E., Chicago, R. F. Schuchardt.

(23,300 volts) there were only five discharges recorded in four months, one on A phase, two on B phase alone, and one on B and C phases together. The simultaneous discharge on B and C phases occurred during a burn-out of the line, probably a breakdown of A phase to ground. One of the B phase discharges took place when a connection between the 9,000-volt coils of the C phase transformer at Division street burned out. A further increase in gap setting was made to 1.25 inches and left for six weeks, during which time A phase discharged when the line broke down. B phase also discharged, but the connection with a disturbance could not be learned. A final increase to 1.3 inches was made. This corresponds to 25,000 volts. During three months there was one discharge on A phase and two on C phase, but here again no cause for the potential rises could be ascertained. Spark-gaps were also installed at the step-up end of the 20,000-volt line in the West Division street substation during a test at that point. They were set at 1.1 inches and during the few hours that they were connected each of the phases discharged heavily at different times. Recently spark-gaps were installed at the Calvary substation. They are set at 1.1 inches and each phase has discharged heavily at times.

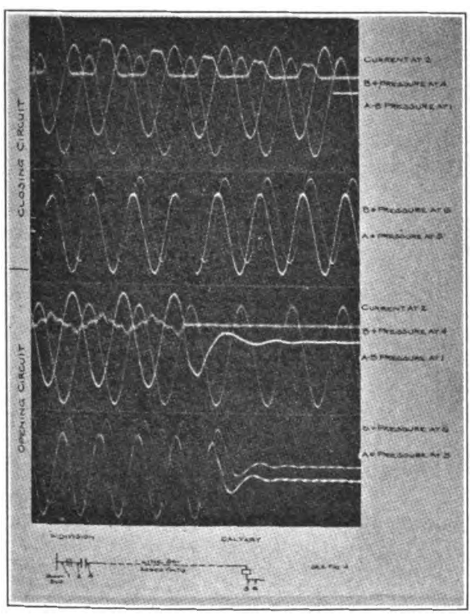

Fig. 2.—Closing and Opening Line No. 501.

An attempt was made with the oscillograph to determine the relation between the potential rises and operating conditions. The oscillograph was connected at various times at the three switching points of the line and some records were obtained for switching operations. Unfortunately the time during which the line could be kept out of service for these investigations was so limited that only a few records could be obtained for each operation. It is recognized that in such a limited number (and especially where, as in most cases, only one phase pressure could be recorded) many disturbances may have escaped detection. However, many of the curves are of considerable interest and may serve to bring out more discussion. A number of them are, therefore, included in this paper. It will be noted that none of the oscillograms shows potential rises as high as those recorded by the spark-gaps. Had more oscillograms been taken, or had all phase pressures been recorded simultaneously, higher rises might possibly have been observed. However, the function of the spark-gap is clearly to detect high potentials, while that of the oscillograph is to show the character of the disturbance and its duration. The spark-gap watches the line continuously while the oscillograph records occurrences for but very brief intervals.

In these figures the source of energy is always from the left, the opening or closing operation being performed on switch marked S. There being but one oscillograph and no pressure wires available, the records at the different substations were not taken simultaneously. The apparatus was set up at one place and curves were obtained for the various operations. The apparatus was then moved to the next substation and the operations were repeated.

Fig. 2 is for closing and opening line No. 501. The current wave in the upper curve is the characteristic exciting current wave of a transformer when first energized. The logarithmic curve due to hysteresis is clearly shown. The dying of the pressures in comparatively slow oscillations when the line and transformers are disconnected is shown in the lower curves.

The curves in Fig. 3 are for closing and opening the entire eleven miles of 20,000-volt line from Division street to Evanston.

Fig. 4 shows curves for closing dead transformers on to a live bus-bar. The first rush of current in this case was nearly six times full-load current. An interesting curve is the one for West Division street showing the duration and amount of the current rush. The curve obtained on opening the switch to the transformers is also given.

The motor of the frequency-changer set at Evanston is wound for 9,000 volts, the line pressure being stepped down in three 200-kilowatt transformers. In Fig. 5 are shown curves obtained when closing these transformers to a live bus-bar. In the upper curve the transformers had previously been demagnetized by keeping them connected to the motor while being shut down until it had come to rest, the fields being kept excited. In the lower curve they had been disconnected at full pressure. The difference in current rush emphasizes the advisability of keeping the transformers connected to a dying machine when shutting down. This applies

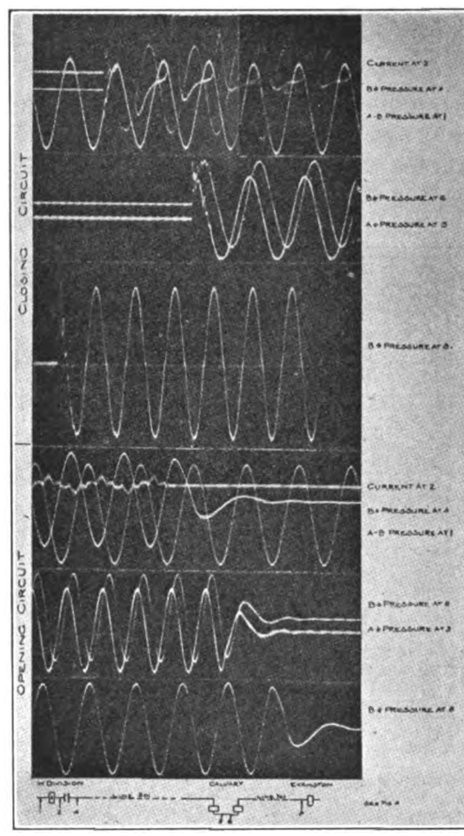

Fig. 3.—Closing and Opening the Entire Eleven Miles of 20,000-Volt Line.

also to transformers of synchronous converter sets.

The curves for starting the frequency-changer set from these transformers show no potential disturbance.

At the Evanston substation there are three 200-watt potential transformers connected in star with their neutral grounded on both primary and secondary. It will be remembered that the 20,000-volt line is grounded solid at the Division street transformers but at no other point. The oscillograph was placed in the neutral connection to ground of the Evanston potential transformers' primary and a current of seventy-six milliamperes was obtained, this amount remaining unchanged even when a resistance of 10,000 ohms was placed in series with the ground connection. The impedances of the three transformers have not been measured but their load is not balanced. In Fig. 6 this current wave is shown taken simultaneously with pressure. The wave for phase-to-phase pressure shows an unstable condition.

From the spark-gaps on the 20,000-volt line we learn then that pressure-rises in excess of 100 per cent occur occasionally. The oscillograms thus far obtained give no clear evidence of the cause, but the cable broke down three times in fifteen months—two of these times in the cable itself, either as a result of these rises or of weakness developed by mechanical stresses imposed upon the cable at the time of installation. This record is reasonably satisfactory, as during the first year's operation we must expect to eliminate the weakest points. The second 20,000-volt line which will complete this

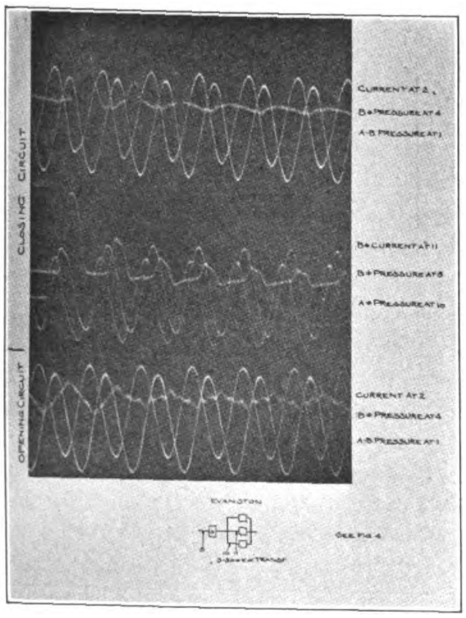

FIG. 4.—CLOSING DEAD TRANSFORMERS ON TO A LIVE BUS BAR.

northern ring is being installed at the present time. After it is put in service the investigation will be repeated. The spark-gaps are kept in service continuously. If dangerous potential rises still exist the remedy will be applied which, in the form of the aluminum arrester, is fortunately at hand. It is, therefore, quite prudent to state that 20,000 volts is a safe pressure for an underground system. Whether a higher voltage will be possible is a matter which has received and is receiving considerable attention.

SUMMARY.

From the viewpoint of the investor or operator the state of the art regarding high-tension underground transmission might be summarized as follows:

1. Underground cable systems of 11,000 volts and under, if properly made, installed and operated, will give at least equally and probably more reliable service than most of the other elements in the electric power system of which the cable system is a part.

2. Where local and commercial conditions justify, pressures as high as 25,000 volts can be satisfactorily used even for systems aggregating as much as a hundred miles of cable. No single line of such a system would be much longer than twenty miles. If higher voltages are needed to meet operating requirements, and can be justified commercially, special construction will be necessary to overcome limitations in paper, rubber or varnished cambric insulation, and also in the standard forms of underground conduit or subways used in this country.

3. On comparatively short lengths, underground or under water, as a part of a long overhead transmission line, cables operating at 40,000 volts can be used.

4. Potential rises of fifty per cent and 100 per cent are not uncommon in large underground cable systems, although this fact may not always be manifest, due to high factor of safety.

5. Definite knowledge of what actually occurs in large high-potential underground systems is still meager, especially regarding intensity and frequency of surges, heating effects and critical temperature for various kinds and thicknesses of insulation, corona effects and similar matters.

In conclusion we would urge all companies having high-potential cable systems to keep a complete and systematic record of all troubles. To quote Dr. Steinmetz:

"To determine the origin and cause of high-voltage disturbances, so as to be able to guard against their recurrence, the most important thing seems to be to very carefully observe and record all the details of the phenomena, even those which appear unessential. The existence of static on switchboards, lines, etc., and the existence of voltages and currents different from those which may be expected, require special attention. Either of these is sufficient to raise the suspicion of some dangerous fault in the system or some dangerous arrangement of apparatus, which requires consideration. . . . The severity of the phenomena depends almost entirely upon the power momentarily available in the system and

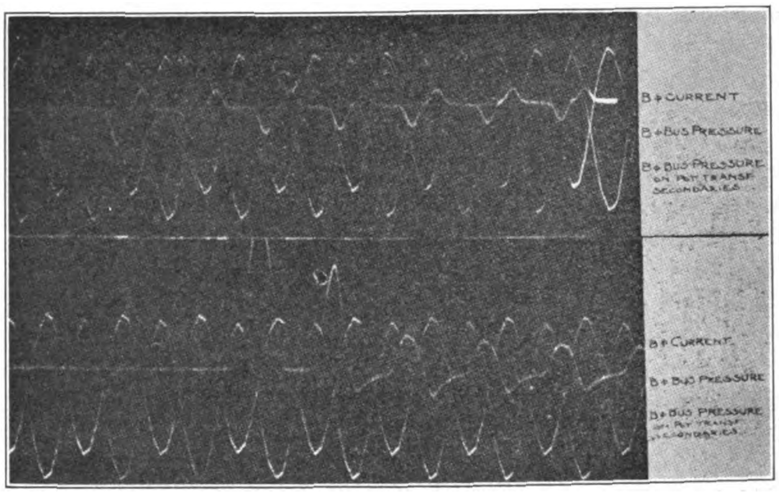

FIG. 5.—CURVES OBTAINED WHEN CLOSING 200-KILOWATT TRANSFORMERS ON TO LIVE BUS-BAR.

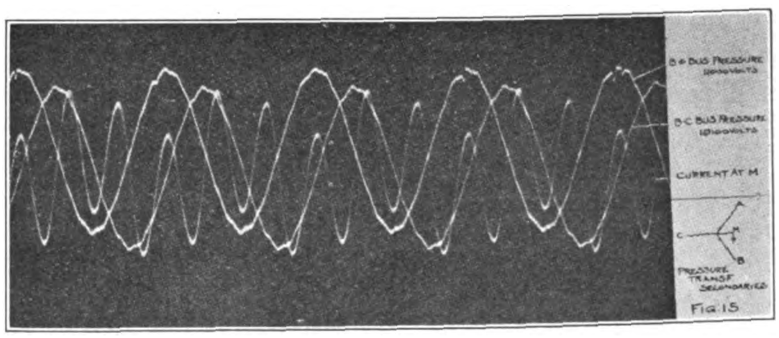

FIG. 6.—CURRENT WAVE TAKEN SIMULTANEOUSLY WITH PRESSURE.

very rapidly increases with the size of the generating stations. With the increasing power and extension of electric systems we must expect to see these disturbances increase in destructiveness. The prospect which this holds out for the future is not very agreeable; it shows, however, the increasing importance for the operating engineer to study and become familiar with the subject so as to be able to cope with the problems which are before him, which perhaps are the most serious in the field of electrical engineering. . . . It would, therefore, be a great help if a far closer interchange of experience existed between different operating engineers."

May we not urge on all engineers to remember these words and to appreciate how, by following Dr. Steinmetz's bidding, we all can help to advance the art?

ADDENDUM.

Spark-Gaps—In using spark-gaps as a means for measuring potentials, certain precautions must be taken to insure reliable results. This fact is, of course, well known. The spark-gaps mentioned in the paper were made up on the usual insulated standard and provided with ordinary No. 5 sewing needles. The series resistance consisted of carbon rods of an amount to limit the current to about one-half ampere at normal pressure. In order to get the correct interpretation for the various settings, the conditions of humidity and temperature of the places where the spark-gaps were installed were duplicated in the laboratory and the gaps were repeatedly calibrated from 0.4 to 1.3-inch gap. Within this range they were found to agree to within about two per cent of the Institute standardization rules. It is safe to assume then that the indications recorded in the paper are correct within five per cent, which is well within the accuracy required for this work.

Where the spark-gaps are in continuous service, to detect occasional high rises it is necessary either to renew the needles daily or to brush the points frequently to avoid an accumulation of dust which would alter the effective gap distances. Any tight enclosure around the gap to prevent this accumulation would introduce errors due to the ionization of the enclosed air. During a discharge the needle points burn to a bead, the size of this bead being an index of the severity of the discharge, and thus roughly of the intensity of the disturbance at that point. A recording meter is placed in series with the gaps to record the time of the discharge.

Oscillograph—The development of a successful portable oscillograph marked an important step in the development of cable systems. It afforded a means for studying the system analytically, so that causes for possible unstable conditions could be determined and guarded against. In the particular application of detecting voltage rises of short duration its usefulness, while still very great, is more limited. The time-interval, already mentioned in the paper, introduces an external limitation. The limitations of the apparatus itself are principally as follows:

1. The free periodicity of the vibrators is less than that of some occasional waves of very short length. In the oscillograph used in the test the vibrators were adjusted for their highest free periodicity, about 6,000 cycles per second. Any peak having a periodicity higher than this would not be correctly recorded. However, a peak of such extremely short duration would have too little energy to cause a harmful disturbance and would thus be of little interest.

2. The vibrator can not be made absolutely dead-beat, but fair results are obtained with five parts of castor oil and one part of turpentine as the damping medium.

3. The self-induction of the vibrator circuit is not entirely *nil*, but is sufficiently low to be practically negligible.

4. The sensitiveness of apparatus can not be made perfect, and its degree of perfection in this regard determines the degree of accuracy of its indications. The amperes per millimetre of deflection of the three vibrators used is from 0.00518 to 0.00578.

While in these four important qualities the oscillograph does not attain the ideal, yet for all practical purposes the apparatus is quite satisfactory. The limited time-interval of application is the most serious shortcoming, and probably the cause for the absence of double-potential peaks on the curves. A great number of oscillograms could be taken, and yet none of them happens to coincide in time with a high peak. This was actually the case in the tests made, during which there was never a spark-gap discharge simultaneous with the taking of an oscillogram.

Reports to the recent meeting in Chicago of the Western division of the American Association of Railway Telegraph Superintendents indicate that within the last two years over 6,000 miles of railroad have been placed under telephone operation.

THE ELECTRICAL FEATURES OF THE GARY (IND.) PLANT OF THE INDIANA STEEL COMPANY.

BY C. A. TUPPER.

The Indiana Steel Company has secured a site of 9,000 acres, with a lake frontage of one and three-quarter miles, on which to erect its steel mills and a residence city for its employés, twenty-three miles east of Chicago, at a point in northern Indiana where the Grand Calumet flows into Lake Michigan. This is the town of Gary, Ind., the like of which exists nowhere else in the world.

The unique and, to engineers, the inspiring feature of this great steel works is the utilization of the entire production of gas from the blast furnaces for useful service in operating blowing engines and in furnishing the source of power for gas engines driving alternating and direct-current dynamos, generating current for light and power.

Eight blast furnaces have thus far been erected, and there are two blowing-engine houses of similar construction to the power-house which contains the electrical machinery. One of the blowing-engine houses is 600 feet long and 104 feet wide. The other is of the same width, but only 530 feet long. The first-named house includes a central pumping and hydraulic power plant equipped mainly by the Snow Steam Pump Works, of Buffalo, N. Y. Besides gas engines, each house contains two steam-driven Tod blowers, but when the plant is in full operation these will not be used. The initial equipment of the plant calls for sixteen blast furnaces. These will produce about 44,900,000 cubic feet of gas per twenty-four hours, equivalent, when used in gas engines, to 500,000 brake-horse-power. Of this quantity approximately thirty per cent is taken for heating the stoves, seven and one-half per cent is diverted to steam-boiler furnaces, five per cent is consumed by various auxiliaries or lost in the process of cleansing, twelve and one-half per cent operates the gas-engine-driven blowers and forty-five per cent supplies the electrical power station.

Each of the sixteen blowing engines consists of a horizontal twin-tandem gas engine of 2,500 horse-power. Eight of the engines were built by the Westinghouse Machine Company and eight by the Allis-Chalmers Company. The power station is 966 feet long and 105 feet wide, with forty-two twenty-three-foot bays. It is located adjacent to the blowing-engine houses and between the blast and open-hearth furnaces. In this station there are installed seventeen horizontal twin-tandem double-acting gas engines running at eighty-three and one-third revolutions per minute. Fifteen of these engines are designed for coupling to alternating-current generators, and two will be connected to direct-current generators. The alternating-current machines are for twenty-five cycles, three-phase, 6,600 volts. The direct-current machines operate at 250 volts. The seventeen generators were built by the Allis-Chalmers Company.

The alternating-current generators are of a type developed by the Allis-Chalmers Company for use with these engines. The laminated stator core is held in a heavy box yoke designed to allow full circulation of air around all parts. The core punchings are held in place by means of dovetails and the armature windings are placed in open slots in the inner periphery of the stator core. The coils are held firmly in place by wedges and, on account of the open-slot construction, can be readily replaced in case of damage. The field poles are mounted on a cast-iron spider and so arranged that they can be removed; the exciting coils are of copper strip wound on edge.

The revolving fields are special in construction, with field poles of solid cast steel bolted to a heavy cast-iron spider; they can, therefore, be readily removed in case it is necessary to get at a field coil. The field-windings are held in place partly by the projecting pole tips and partly by brass rings running completely around the rotor on each side and fastened to the top of the poles by long brass screws. The construction, combined with the solid poles, gives a large damping effect, prevents hunting and aids in securing parallel operation.

The direct-current generators have also been designed with particular regard to this service, but in general are similar to the Allis-Chalmers Company's standard engine-type machines.

In connection with the generators the Allis-Chalmers Company has furnished Cutler-Hammer remote-control field rheostats and field switches. The controlling apparatus is located in the basement as near as possible to the generators and is operated from the bench board located in the power-house gallery. These rheostats are of a unique design, being what the manufacturers call the "cross-head" type. They are driven by means of vertical motors and are provided with automatic devices which insure the stopping of the motor at either limit of the "cross-head" travel, that is to say, either when all resistance has been cut in or out of circuit. Means are provided, also, for operating these field rheostats by hand in case of damage to the motor.

The power generated will be distributed throughout the works and used to operate the heavy induction-motor-driven rolls, the tilting and feed tables for the various passes, the hot saws, hot and cold pull-ups, hot rolls, transfer tables, straightening and drilling machines, cold saws, elevators, conveyers, pumps and a multitude of machines and mechanical devices auxiliary to the operation of such an enormous plant. Several of the motors built by the General Electric Company for these works are of 6,000 horse-power each, being designed for driving the rolls, and from this they range in size down to machines of the smallest capacity used to operate switches in the power-house.

The problems of control presented by the multitude of motors installed at this plant involve many interesting features, the solution of which was largely intrusted to the engineers of the Cutler-Hammer Manufacturing Company, of Milwaukee, and the automatic devices now installed at Gary represent the most recent developments in electric control as applied to steel-mill machinery.

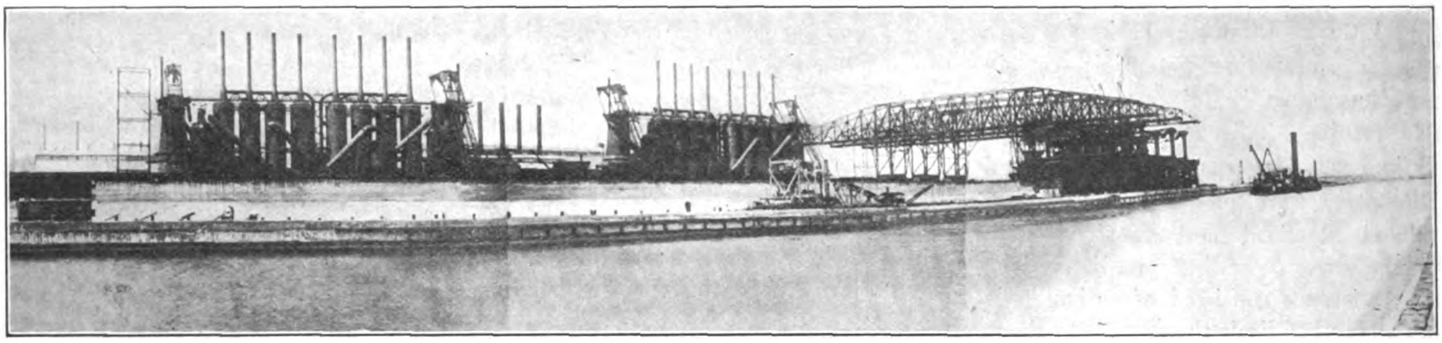
The electrical system as a whole is subject to central control at a switchboard operated from a gallery sixteen feet high. This switchboard, which was designed by the Western Electric Company, has the usual complement of instruments of standard types, and a detailed description would involve more space than can be given to the subject here.

To aid in securing maximum economy under heavy fluctuations of load, by utilizing the full value of the generating power of the gas, without regard to the amount of current required at any given time for the operation of the mills, a storage-battery installation furnished by the Electric Storage Battery Company has been housed in a two-story building, eighty-seven feet long by forty-seven feet wide, located near the power station. The batteries will be kept charged as nearly as possible to their full capacity in order to assist in meeting, for a considerable period of time if need be, any demands for excessive power made upon the gas-engine-driven generators. These can, in themselves, be heavily overloaded, but the best power-factor is, of course, to be secured at about their rated capacity. The battery also aids in maintaining, at light loads, a constant pull on the generating equipment.

The subfoundation of the power station, as well as of each blower-house, is a solid mass of concrete underlying the entire structure on the level of Lake Michigan, and having a depth of five feet. Above this are separate foundations for each of the generating and blowing units.

The arches forming the roof of the power station have a clear span of eighty-five feet, providing headroom, at the dome, of seventy-three feet above floor level. The station is served by two fifty-ton cranes. Roofing is heavy galvanized corrugated steel. The interior walls for a distance of ten feet are of white enamel brick, but above that point the surfacing is in red pressed brick. The exterior consists of red building brick.

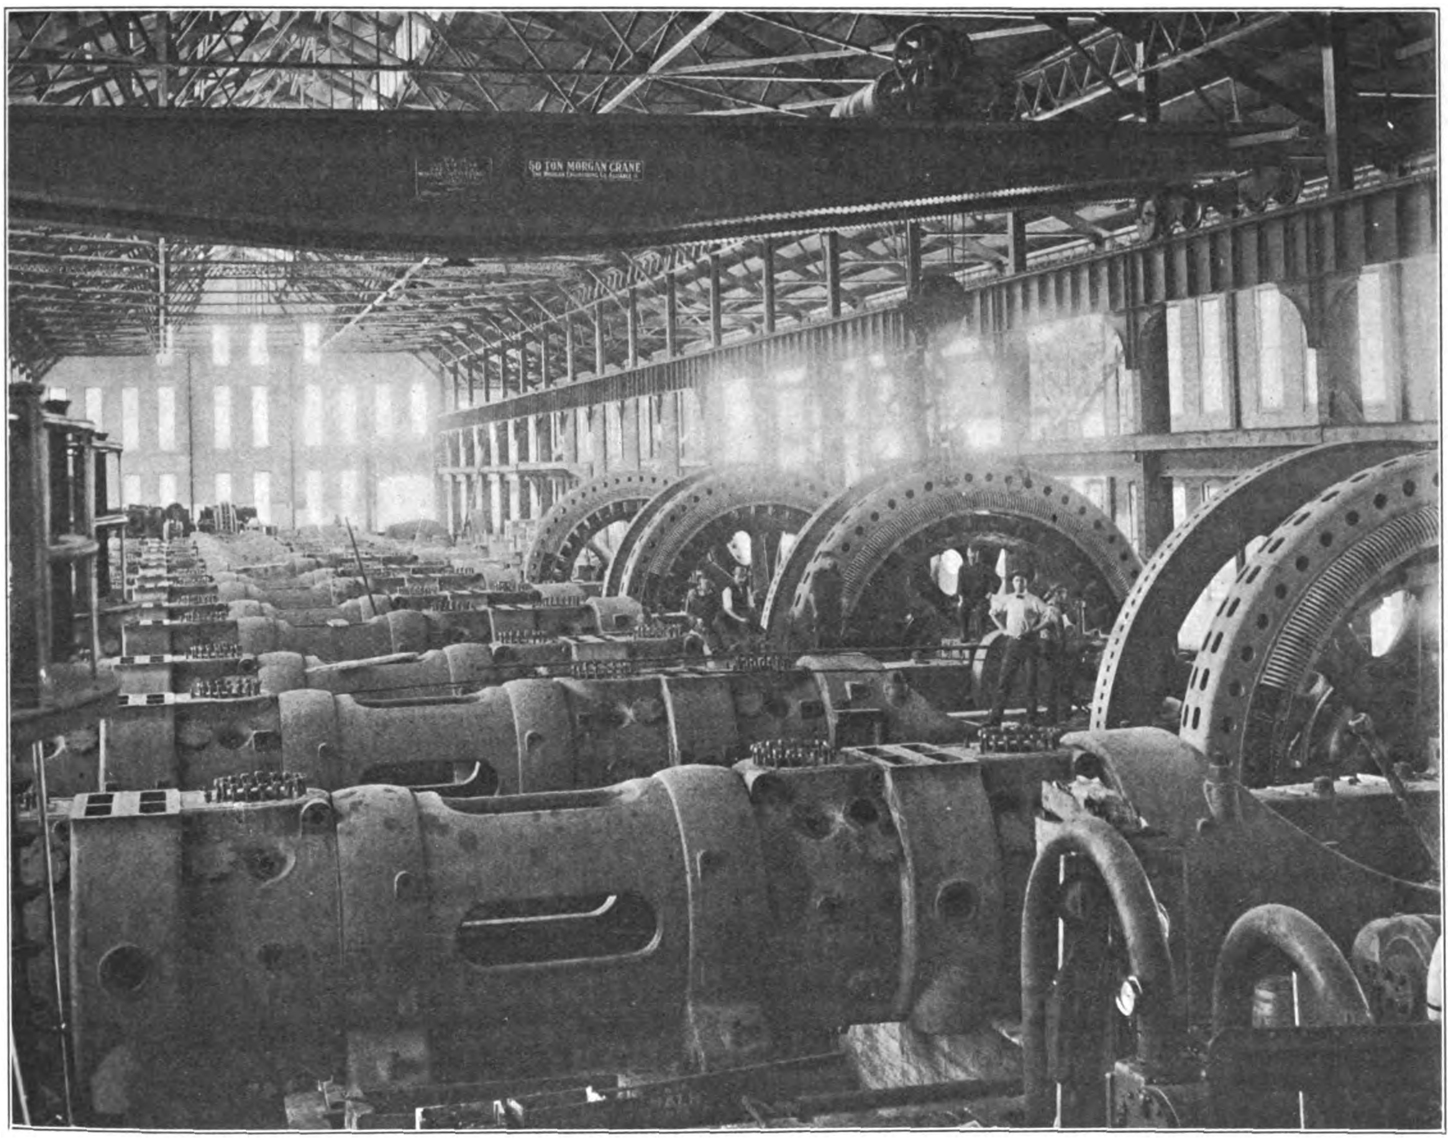
The plans of the plant provide for six batteries of basic open-hearth furnaces,



VIEW OF BLAST FURNACES FROM WATER-FRONT, INDIANA STEEL COMPANY'S PLANT, GARY, IND.

fourteen to the building, of which two batteries, or twenty-eight furnaces, are at present constructed.

With the four open-hearth buildings, now completed or under construction, in operation the Gary plant will have a capacity of over 12,000 tons of steel per day, or 2,000,000 tons per year. With all six buildings in use, the total capacity of the plant, as planned by the United States Steel Corporation, will be upward of 4,000,000 tons per year.



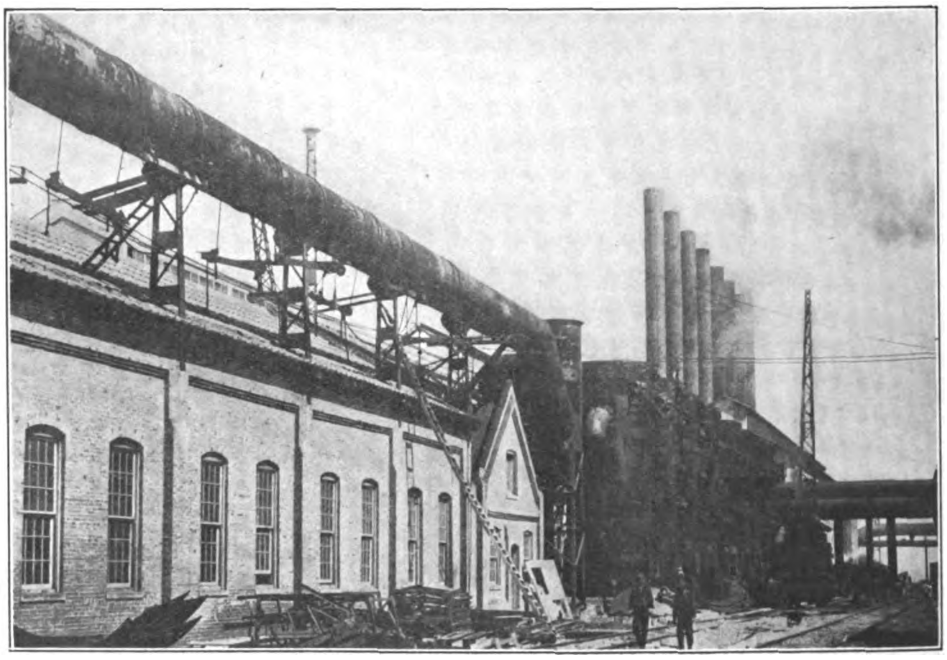
View in Central Station, Indiana Steel Company's Plant, Gary, Ind., Showing Gas Engines and Generators in Course of Erection.

With everything running at top notch 4,000 tons of steel rails can be produced daily; and in normal operation the mill is expected to turn out 100,000 tons per month.

The group of rail-mill buildings, located about 300 yards from the lines of the open-hearth furnaces, constitutes in itself an enormous plant. The main structure is 1,800 feet long, and at right angles to it is another building of one-third the length, with a width in a single span of eighty-five feet. This contains twelve soaking pits or furnaces, each of which is supplied with gas from an independent Hughes mechanical gas producer. The arrangement here is such that ingots enter from the open-hearth furnace buildings along the entire length of one side of the pit building, the other side being reserved for the electrically operated ingot buggies which transfer the heated ingots through the first stand of rolls. Each of the twelve pits has four holes, six feet by six feet, and is provided with the usual equipment of hydraulic cylinder covers and reversing air and gas valves of the well-known Dyblie type. The ingots used are twenty inches by twenty-four inches and six feet long, weighing 8,500 pounds each. For the operation of the two ingot buggies used, Cutler-Hammer Manufacturing Company, of Milwaukee, has developed an ingenious system of control. On account of the length of the building in which the soaking pits are located, it is impossible for the operator stationed at the mill to see when an ingot buggy is opposite a particular pit. It was, moreover, deemed necessary to guard against the possibility of the operator becoming confused and bringing both ingot buggies to the mill at the same time, which would result in a collision. The special controlling system provides guards against this contingency, at the same time enabling the operator to automatically stop the ingot buggy at any of the pits. There are two master levers for the control of the two buggies. Each of these levers can be set in any of eight positions, one corresponding to the rail mill itself, six to the six soaking pits which each buggy serves, and one "off" position. If, when one of the ingot buggies is at the mill, the operator desires it to go to pit No. 5, let us say, and there stop, he merely moves the controlling lever to the position corresponding to pit No. 5, and the buggy proceeds to that point and is there automatically stopped. A suitable interlock between the two controlling levers is provided which renders it impossible for the operator to throw both levers to the mill position at the same time, thus insuring a clear track for each buggy.

The rail mill is equipped with twelve sets or stands of roll trains, all operated at varying speeds by General Electric alternating-current motors, some of which are of the largest sizes ever constructed for industrial service. These are housed in a separate bay or "leanto" running parallel with the rolls. The rotors are twenty feet in diameter and have a speed of eighty-three revolutions per minute. All of the motors are connected directly to the roll trains by regular mill couplings. The aggregate driving capacity is 24,000 horse-power. Although the motors are provided with flywheels and operate in one direction, provision is made for reversing in case of necessity. The control system has been worked out with the greatest nicety, all operations being under the instant control of the operator by means of a master controller.

The first group of rolls consists of four stands of continuous forty-inch mills, each two of which are driven by a 2,000-horse-power motor. They are arranged in tandem, requiring no manipulation from stand to stand. Here, as elsewhere through the plant, sufficient distance is left between successive sets of rolls to enable a quarter turn of the ingot or bloom to be made, so that it is worked equally on all sides. The first two mills are at present equipped with forty-two-inch rolls, enabling twenty-inch by twenty-four-inch ingots to be used. After passing these four mills the ingot is sent to a forty-inch three-high blooming mill equipped with lifting tables and arranged with a combined hydraulic and pneumatic balancing device. This mill, which is operated by a 6,000-horse-power motor, gives the ingot five passes. After being bloomed the ingot is sheared in a ten-by-ten-inch horizontal blooming shear, and the crop ends or butts are taken outside of the mill by a butt conveyer of unusual construction, which was designed and built by the engineers of the Indiana Steel Company. Each bloom then goes through a twenty-eight-inch roughing mill, which is three-high and equipped with tilting tables. This mill has actually three stands of rolls. The roughing stand, however, is the only one that is three-high, the other two stands being two-high. The mill is driven by a 6,000-horse-power motor and gives the bloom three passes. After leaving the roughing mill the bloom goes through a two-high twenty-eight-inch forming mill driven by a 2,000-horse-power motor, receiving but one pass. Then it is sent to finishing mills, which consist of five stands of twenty-eight-inch mills driven by two 6,000-horse-power motors. After the dummy pass the bloom is transferred to the first edging, which is in this same mill but the second stand, and turns back on an elevated table to the second edging, which is in line with the twenty-eight-inch roughing mill. It then travels by chain transfer to the lower tables, and on the leading pass goes through a stand which is also in line with the roughing mill and driven by the same motor and continues on to the third stand of the twenty-eight-inch finishing mill, this being the eighteenth and last pass. After the finishing pass the rail travels through to the saws, of which there are five provided, thus cutting four rails to length. These four rail lengths consist of half the ingot. As the capacity of this dinarily large air space to facilitate the rapid cooling of the rails. The finishing building is 1,383 feet long, central with the hot beds, and provided with live rolls extending the entire length. The roller tables are equipped with stops and kick-offs to transfer the rails to the straightening presses, of which there are sixteen, built by the Hilles & Jones Company, of Wilmington, Del., these being of the usual type and motor-driven. From the straighteners the rails are transferred by the usual skids to three-spindle vertical drill presses furnished by William Sellers & Company, of Philadelphia, which are also motor-driven. These complete the rails for use. From the drill presses the rails are transferred to a roller table, which extends the full length of the building, and from which the rails may be skidded to the loading beds immediately outside of the building.



SECONDARY WASHERS OF GAS-CLEANSING SYSTEM, SHOWING BOILER HOUSE AT EXTREME RIGHT, INDIANA STEEL COMPANY'S PLANT, GARY, IND.

mill is 4,000 gross tons per twenty-four hours it will be seen that there must be a four-rail length sawed about every half minute. The saws are forty-two-inch blades, arranged to be raised and lowered in unison by one controller from the hot-saw operator. After leaving the hot-saw run the rolls pass over the usual cambering machine and are run onto hot beds, 100 feet long, of which four are at present installed, with provision made for an additional two, if necessary. These hot beds extend to the south of the mill proper. In the finishing-mill section they are of unusual design, being made of structural material and placed eight feet above the floor, allowing for an extraor-

The principal machinery was built and installed by the United Engineering and Foundry Company, with the exception of the finishing department, which was erected by the Morgan Engineering Company. For the lifting tables and transfers Westinghouse motors are used.

In the rail mill a number of Cutler-Hammer automatic remote-control devices are installed, the most interesting of which are those designed for the control of the elevating and tilting tables, the bloom shear and the transfer. The elevating table on the forty-eight-inch blooming mill, weighing about 250,000 pounds, is supported on huge bell-cranks which are connected to a rotating crank driven by a 250-horse-power motor operating at 150 revolutions per minute. By means of automatic controlling devices the throwing of a master lever starts the table from the low-level position and raises it to the highest level, where it is automatically stopped. In lifting the table from the low to the high level, the rotating crank moves through an arc of 180 degrees and, on throwing the master lever to the reverse position, the crank revolves another 180 degrees in the same direction, bringing the table to the low level once more. The operation of raising or lowering the table can be accomplished in a period of two seconds, which is quite remarkable when the masses to be accelerated, slowed down and stopped are considered. Its arrangement is similar to that of the elevating table, one end being pivoted and the other end supported on a bell crank. The tilting table is driven by a 150-horse-power motor controlled by a controller similar to that designed for the elevating table. The bloom shear is operated by means of a seventy-five-horse-power induction motor and the pin on the clutch by a direct-current auxiliary motor of five horse-power. The circuit of this motor is interlocked with the controlling device for the seventy-five-horse-power alternating-current motor so that the former can not be put in motion except when the latter is running at full speed. The latch is operated by a crank to which the five-horse-power motor is geared. Pressure on a push-button under control of the operator causes the motor to run long enough to revolve the crank 360 degrees, thereby releasing the clutch and returning the pin to the initial or "off" position.

Automatic controllers installed in connection with motors on the transfers make it possible for the operator to transfer the rail from one table to another by a simple throw of the lever, the motor being automatically stopped after the transfer has been completed.

For the operation of cranes, tables and other apparatus, in and about the rail mill requiring direct current, two 500-kilowatt synchronous motors driving direct-current generators have been furnished by the General Electric Company. This equipment, with the necessary switchboards, is located in one of the motor houses at the rail mill and designated "Substation No. 1." Other substations suitably equipped are being located in other sections of the plant.

The billet mill consists of four continuous stands of forty-inch blooming mills, each two of which are driven by a 2,000-horse-power motor. After leaving these the ingot is turned end for end on a turntable and passes through a five-stand thirty-two-inch continuous mill, the entire mechanism of which is driven by one 6,000-horse-power motor. At the end of this mill is placed a twelve-inch by twelve-inch horizontal blooming shear and also a ten-inch by ten-inch vertical blooming shear, from either of which shears either sale blooms or blooms for the twenty-four-inch mill immediately following may be sheared. The sale blooms are run out on hot beds on the other side of the building where there is a loading yard equipped with overhead traveling cranes. Blooms intended to be further reduced after being sheared are sent through the twenty-four-inch continuous mill, which consists of six stands driven by a 6,000-horse-power motor, reducing the blooms to four or five inches square. At the end of the twenty-four-inch mill is placed a roller table. The billets may be transferred to an eighteen-inch continuous mill to be further reduced or, if for sale, to a shear and from thence to overhead billet pockets from which they may be loaded directly into cars.

For the further reduction of billets taken from the above-mentioned transfer skids the billets are run through an eighteen-inch six-stand continuous mill, driven by a 6,000-horse-power motor and equipped with flying shears.

All of the machinery is electrically driven, General Electric, Crocker-Wheeler and Westinghouse motors being used. This machinery was also furnished by the United Engineering and Foundry Company.

The additional mills to be built are a sixty-inch universal plate mill, which will be the largest of its kind in the world, and a forty-four-inch by 160-inch sheared-plate mill. These two mills will each be served by a thirty-two-inch slabbing mill. Further extensions to the Gary works include an axle mill, structural mill and eighteen-inch, fourteen-inch, ten-inch and eight-inch merchant mills.

The plant for handling ore from the vessels consists of Hulett unloaders and Hoover & Mason bridges of sufficient capacity to furnish material for the eight blast furnaces already built, each of which will deliver 500 tons of pig-iron daily, and for the eight additional furnaces yet to be constructed.

The ore bins and auxiliary apparatus were constructed by the Brown Hoisting Machinery Company, of Cleveland, Ohio, except the electric hoists operating the skids to the blast furnace tops, which are of the Otis Elevator Company's standard design for this service.

In connection with the furnaces and mills of the steel plant proper there have been erected a group of buildings of general utility, consisting of a machine shop, foundry, boiler shop, blacksmith shop, pattern and carpenter shop, pattern storage building, roll shop, electrical repair shop, brick storage house and a very well-equipped general store house. There has also been provided a yard-locomotive house, which is rectangular in shape, with tracks running through on an angle from one side to another, thus avoiding the use of a turn-table.

With all of the power economies which the plant of the Indiana Steel Company possesses, ridding it of gas and smoke, Gary will be one of the few examples of a clean city located near iron and steel works, and every effort is being exerted to make it a model town of its class. The steel company, through its real estate department, the Gary Land Company, has already built about 500 houses of various types and sizes. At present Gary has about 8,000 residents, and it is an incorporated city.

In addition to seven steam roads, most of which are trunk lines, there is a street and interurban electric railway running east and west and north and south through the town, connecting it with the various manufacturing centres located along the southern shore of Lake Michigan, as well as with lines running directly into Chicago.

In practically all respects Gary will be quite different from other communities built under somewhat similar conditions. There will, as a recent writer has said, "be a marked absence of the hovels, dirt and squalor so pronounced a feature of most manufacturing cities." It is to be a clean city, free from smoke and soot, principally because a great corporation has learned how to conserve the appalling misuse of fuel from which these evils spring; and, with the magnificent start which has been given the community, both civic and individual pride will undoubtedly keep municipal affairs upon a higher plane than is common to large industrial centres. Gary stands for a long step ahead in the great economic movement toward elimination of waste, whether material, mental or moral; and its welfare is of genuine concern, not only to the Indiana Steel Company and to its inhabitants, but also to the nation at large. The officers of the Indiana Steel Company are: E. J. Buffington, president; G. C. Thorp, vice-president; T. J. Hyman, secretary and treasurer; K. K. Knapp, general counsel.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Influence of Electricity on the Growth of Plants.

Among the manifold methods for advancing the growth of plants by electricity that of Lemstroem is again attracting particular attention. The investigations of Professor Lemstroem, of the University of Helsingfors, who died two years ago, have extended over more than a lifetime. His observations of plant growth in northern regions, which is striking on account of its unusual rapidity and luxuriance, led him to the conclusion that special causes must be at work here, which partly substitute warmth, the principal factor in plant growth. He found the cause in the stronger atmospheric discharges in northern regions, of which the aurora borealis is a notable example. After some successful experiments with plants in pots, Lemstroem erected a net of wires over larger surfaces of land, which in most cases he charged positively by means of a static machine, while the negative pole was connected to the ground, and permitted a dark discharge to influence such an experimental field during the entire period of vegetation, while a control field nearby remained uninfluenced. The experiments were carried on in different latitudes, and with correct treatment always resulted either in an increase of the crop varying between eighty and 100 per cent, or a shortening of the period of ripening, or else in a marked improvement of the quality. The largest surface experimented upon by Lemstroem was 3.5 hectares (about eight acres). A remarkably small quantity of electrical energy was necessary, a one-tenth-horse-power motor being sufficient to drive the static machine. Lemstroem considered electroculture ready to play an important part in agriculture and horticulture on a large scale, for improving the quantity and quality of crops, but there were still a number of practical considerations in the way of putting the method into practice. One was the imperfect way of producing static electricity by the unreliable and inefficient static machine; another the inconvenience caused by the presence of the wire net during the cultivation of the soil. It was necessary for the technical man to perfect this part of the process. This was done three years ago by Mr. Newman, in England, who tested the method practically on a much larger scale. He succeeded in interesting Sir Oliver Lodge, who proposed the use of special mercury rectifiers patented by him for obtaining the necessary high-tension direct current from alternating current transformed to a high pressure. The tension used is 100,000 volts, but is entirely harmless on account of the extraordinarily small amperage of the current. According to a recent report of Sir Oliver Lodge the experiments have been extended during the years 1906 to 1908 to a surface of ten hectares (about twenty-five acres), and it was demonstrated that with the high tensions employed the wire net may be at a height of five metres above the ground without destroying the beneficial effect. This height will not interfere with any agricultural labors; Lemstroem was obliged to prescribe a height of not more than forty centimetres because of the ineffective apparatus employed by him. Improvements have also been made in the construction of the wire net without apparently decreasing the effect, so that the entire method now seems to be ready to be successfully put into practice.—*Translated and abstracted from Elektrotechnische Zeitschrift (Berlin), September 17.*

New Facts About the Quartz Lamp.

Some peculiarities of these lamps, which have been extensively adopted since their introduction in the fall of 1907, are pointed out by Oskar Bussmann. The quartz lamp is a mercury vapor lamp made of pure fused quartz. As this material can withstand extraordinarily high heat without softening, the mercury vapor arc can be brought to much higher temperatures than in glass tubes. It has been shown that the economy of the mercury arc in glass tubes increases with the rise of temperature up to a certain degree and then diminishes again; but when the fused quartz is substituted for glass and the temperature raised still higher than is practicable in glass tubes, it is found that a great increase in economy takes place before the quartz begins to soften and far exceeds that of common arc lamps. Quartz also has the advantage of being absolutely insensitive to temperature changes, as its expansion coefficient is almost equal to zero, and therefore red-hot quartz can be plunged into cold water without cracking. This property contributes greatly to the strength and life of the lamp. The burner consists of a quartz tube six centimetres to twelve centimetres long and one centimetre to one and one-half centimetres in diameter. It is arranged in a nearly horizontal position. Two small tubes are fused across the ends and contain the mercury into which the terminals are led. The real source of light is the arc passing between the mercury poles through the tube. The arc is started by bringing the mercury electrodes in contact with each other and then separating them. This is done automatically by an electromagnet which tilts the lamp when it is switched on. The quartz tube must be highly evacuated, as otherwise it is difficult to produce an arc. When the arc is started mercury is vaporized at the poles in large quantities and the vapor pressure increases according to the load. In glass tubes the pressure rises to two millimetres to three millimetres under normal conditions, but the quartz burner is strained to 760 millimetres mercury column (one atmosphere) which equals the atmospheric pressure outside, and so there is no strain on the burner during operation. The economy of the quartz lamp is the higher the greater the pressure inside of it. But it is undesirable to use pressures above one atmosphere as the quartz might crack. In glass tubes the bluish mercury vapor arc fills the entire interior uniformly. Its temperature is only 300 degrees to 400 degrees centigrade. When a quartz lamp is started the arc also fills the entire tube, but after a few minutes, as the vapor pressure rises, it recedes from the walls and contracts toward the middle of the tube, until finally it forms a band in the centre about five millimetres in diameter. At the same time the violet-blue tint of the light changes to a yellowish green and its intensity increases enormously. During the starting period the lamp absorbs only twenty-five to thirty volts, but when the pressure has increased to one atmosphere the tension is about 180 volts. The time necessary for attaining the definite vapor pressure and full light intensity naturally depends on the amount of energy supplied to the lamp. If 3.5-ampere lamps were supplied from the beginning with 3.5 amperes, they would absorb only $3.5 \times 25 =$ about ninety watts, which is not sufficient to bring the mercury to boiling temperature; therefore the initial current intensity must be as high as the operating conditions will permit, which may be considered to be ten amperes for 3.5-ampere lamps. This requires a resistance of at least nineteen ohms on 220-volt circuits. The gradual regulation of the resistance is effected automatically by employing resistances of iron wire. Iron has a high temperature coefficient and its resistance quadruples when it is brought to a light-red heat. The dimensions of the wire are so chosen that the high initial current intensity of the lamp will bring it to a light-red heat, and it therefore takes up about 130 volts, but at the definite current intensity of 3.5 amperes it is only slightly heated and absorbs no more than fourteen volts. The quartz lamp is furthermore provided with an adjustable resistance in order to adapt it to the different pressures in use, 220 to 240 volts.

The metallic conductors through the quartz walls of the mercury vessels must have the same coefficient of expansion as quartz and must not be attacked or dissolved by the mercury; and the only material suitable for this purpose was found to be the nickel steel discovered by Guillaume, of Paris. The right temperature of the pole vessels is essential to the proper working of the lamp, as it determines the vapor pressure in the lamp and the intensity of the current flowing through it. In order to adjust the cooling of the pole vessels according to the conditions under which the lamp is used —exterior or interior lighting—they are surrounded by peculiar coolers of copper sheet, whose radiation surface may be varied. Quartz lamps should be used without a globe only when their ultra-violet rays are to be utilized, and in such cases employés near them should protect themselves from these rays which produce skin inflammation. If light of better color is desired, it can only be obtained by using incandescent lamps in connection therewith. The fact that the Koerting & Mathiesen Actien Gesellschaft, the Illgemeine Electrizitäts Gesellschaft and the Siemens-Schuckert Works have united in introducing these lamps would seem to indicate that they are considered of importance. — *Translated and abstracted from Elektrotechnischer Anzeiger (Berlin), September 10 and 17.*

MEASUREMENTS WITH PORTABLE INSTRUMENTS.[1]

BY F. P. COX.

Inaccuracies in reported values may be divided into two classes—those due to errors of the observer and those due to the errors of the instrument. Under the former must be included errors due to incorrect connections, which are by no means unusual in the measurement of polyphase circuits, errors due to not noting and allowing for zero errors in the instrument and errors due to parallax which may be avoided by properly using the image of the needle reflected from the mirror under the scale.

The personal equation of an observer which causes one man to read the needle as above and another as below the true position, need not be taken into account in commercial measurements. When a needle is fluctuating through a considerable angle, it is sometimes difficult to estimate its true position. If the most dead-beat instruments available are used, no further precautions are possible, except to take the average of a considerable number of readings. These readings should be jotted down as fast as they can be taken and no attempt made to obtain the average reading by estimating with the eye the mean position of the needle. Even with this precaution, great reliance must not be placed on observations taken under unfavorable conditions. The results, at best, are approximate.

A fruitful source of error is the habit of reading instruments when the deflection is small. The average observer, using a reasonable amount of care, can not be relied upon to estimate the position of a needle much closer than one one-hundredth of an inch, and at one-fifth scale the error introduced is five times the magnitude of a corresponding error at full scale. It is recommended that deflections of less than twenty per cent of the full scale be classed as approximate. All instruments have errors due to temperature changes and are affected by local magnetic fields. The errors so introduced may be a very small fraction of a per cent or they may amount to several per cent, depending upon the design and type of instrument. Local field errors may be noted and, if not too great, allowed for, by reversing the leads to the instrument or by turning it through 180 degrees. The mean value of the observations should be taken as the correct reading. It must be remembered that local fields are found, not only in the immediate vicinity of buses carrying large currents, but also some distance away where they have been carried by the iron framework of the switchboard or of the building. Sometimes an unshielded instrument is read when resting on the iron grating of a switchboard gallery or on a hand rail, and errors of considerable magnitude may result. Such errors can not be corrected by reversing the position of the instrument or by reversing leads, since they are due to the presence of a mass of iron in the vicinity of the instrument.

Scale errors, due to incorrect marking, are generally small, not amounting to over two-tenths of a per cent, and are most liable to be found in the subdivisions of the scale, since each subdivision is not an observed point. It is customary to observe and check the principal divisions, in some cases the half divisions, and to interpolate the intermediate ones.

Care of instruments or, rather, want of care, should be considered as a very important source of error. Shelves provided with a thick felt covering should be used for storing them. Such shelves are inexpensive and pay for themselves in reduced repair bills and improved accuracy. The instruments should be in charge of one competent man who will examine their condition when they are returned to his stock. He should see that they are compared with suitable standards once or twice a month and frequently cross-checked. He will soon determine which employés are treating the instruments properly and which are abusing them. Such abuse may consist in careless handling in use or in transportation. In riding in street cars the careful instrument man will keep his instruments in his lap or on the cushioned seat. The careless man will drop them on the floor. In sending instruments out by wagon felt-lined boxes should be provided to protect them in transit. It is well to purchase instruments of high torque and robust constitution, but it should be remembered that the term "robust" is only comparative. Instruments should be given the same care which is given to a valuable watch, and no matter how strong the instrument may be, it will not be improved by rough handling.

The measurements which are most commonly made by lighting or power companies are of potential, current, energy and time. Perhaps the latter might seem rather beyond the scope of this paper, but it is an important factor in the calibration

[1] A paper read at the twenty-fourth annual meeting of the Association of Edison Illuminating Companies, held at Lenox, Mass., September 15, 16 and 17, 1908.

of meters and it seems advisable to make some mention of probable errors in this measurement.

POTENTIAL.

In considering the subject of errors in measurement of potential, it is necessary to divide this subject into two types of circuits, continuous and alternating currents. It is well recognized that the best type of instrument for measuring continuous-current circuits is the D'Arsonval. For economy of energy absorbed and deadbeat qualities, this instrument is a most satisfactory one. The best instruments of this type have a resistance of about 100 ohms per volt of scale reading. The errors introduced by temperature changes are insignificant, except in those multiple-scale instruments which have a tap for one and one-half or two volts full-scale reading. Where this tap is used the accuracy of the low-reading scale should be regarded with suspicion, since it is liable to have a temperature error of about one-tenth of one per cent per degree centigrade. This type of instrument, when provided with a iron case, is practically shielded from all ordinary magnetic fields. Normal earth's field introduces an error of about one-tenth of one per cent in unshielded instruments and such instruments should not be used nearer together than eighteen inches. If placed side by side these instruments react on each other and an error of one per cent may very readily be introduced.

The generally accepted model of voltmeter for measuring alternating potential is of the dynamometer type. Those designed for 110-volt circuits have a resistance of from 1,500 to 2,000 ohms or about twelve to fifteen ohms per volt. The resistance of the instrument is somewhat affected by temperature on account of the percentage of copper which it contains, but this is almost exactly compensated for by a corresponding temperature effect on the spring. Double-scale instruments of this type should be limited to a ratio of 2 to 1 between scales, or with special designs, 4 to 1. When designed for the higher scale, bringing out a tap for less than half scale introduces more copper in the circuit than the spring will compensate for, and frequency errors must be expected on account of the change of the instruments' time constant. In building double-scale instruments with a ratio of 4 to 1 between scales, it is customary to design them so that frequency and temperature errors are negligible on the lower scale. The result is an instrument which takes a large current, and the key must not be permanently depressed on the high voltage. Even special design will not permit self-contained instruments to be made with a ratio of more than 4 to 1 between scales, and greater ratios should be obtained by means of external multipliers. These dynamometer instruments should be protected by means of a suitable shield from any ordinary magnetic field, since, unshielded, they have an error of about one per cent, due to normal earth's field.

Although designed primarily for alternating currents, when there is no very marked difference between reversed readings they may be used on continuous-current circuits by considering the correct reading as the mean of the reversed observations. When used with potential transformers the errors of the transformers must be added to the normal instrument error. Account must be taken of the regulation of the transformer, as affected by the connected load and also by the frequency of the circuit on which it is used. A regulation of from one and one-half to two per cent between voltmeter load and full load is not improbable. The correction factors for the transformers can be supplied by the builders and should be taken into account where best accuracy is desired.

CURRENT.

The D'Arsonval ammeter for measurements on continuous-current circuits differs from the voltmeter only in regard to errors due to temperature. In this respect, however, it differs materially and is often credited with an accuracy which it does not possess. Temperature changes affect the accuracy of the instrument in three different ways.

First, in those types of instrument where an attempt is made to avoid errors on account of change in room temperature, it is necessary that the shunt should have the same temperature coefficient as the instrument itself; and, since this coefficient is not low, five or ten minutes after such instruments have been connected, errors of two or three per cent, or even more, may be noted. These errors are due to the fact that the shunt is absorbing energy and increasing in temperature more rapidly than the measuring circuit.

Second, where an attempt is made to avoid the error by making the shunt of zero temperature coefficient material, an error, due to change of room temperature, is introduced. Since the temperature coefficient of the measuring circuit is practically half that of copper, an error of one-tenth or two-tenths of a per cent is caused by each degree centigrade, which the room temperature changes. This error may, however, be reduced to a negligible quantity by using shunts which have a drop of 200 millivolts in place of the forty or sixty millivolts used in switchboard shunts. The extra size and weight are well warranted on account of the improved accuracy obtained.

The third error is found in those shunts which have zero coefficient materials and is due to thermoelectric currents set up in the measuring circuit. These currents are caused by difference in temperature of the shunt terminals. Such differences in temperature may be due to improper contact with the bus, to a difference in circulation of air at the two ends, or more usually, it is due to the Peltier effect. Such thermoelectric currents may be avoided by using materials which have practically no thermoelectric difference of potential between the metals of the terminal and the shunt strip, or by adding a thermoelectric compensator which sets up a thermoelectric effect of equal magnitude and opposite sign.

Ammeters for the measurements of alternating currents are usually of the iron-vane type. The only error which is characteristic of this type of instrument is that due to variation in wave form and this error is within one-half per cent. When used with current transformers, errors of considerable magnitude may be introduced. These errors increase as the impedance of the secondary circuit of the transformer increases and as the primary current diminishes. Where a five-ampere instrument is used as the only load on the secondary circuit of the transformer, above one-fifth scale inaccuracies greater than one-half per cent are not liable to be found. It is not permissible to substitute a two-ampere instrument for lower readings unless the corresponding curve of the transformer under the new condition is at hand, for the inductance of the two-ampere instrument is more than six times that of the five-ampere and this additional load on the secondary introduces considerable error. Where transformers, in addition to the portable ammeter, carry a load of one or two stationary instruments and a tripcoil, an error of three per cent to five per cent at one-tenth load is by no means improbable and an error of one-half per cent at full load is to be expected.

ENERGY.

Portable indicating wattmeters for the measurement of energy are of the dynamometer type and on continuous-current circuits, or non-inductive alternating circuits, their characteristics do not materially differ from those of the dynamometer type of voltmeter. But when used on highly inductive circuits, or with transformers, additional errors are introduced. Errors due to mutual induction of the two circuits are small and may be neglected in commercial measurements. Errors of self-induction may not be neglected in measuring highly inductive circuits such as core losses of some transformers. The best instruments have an inductance of potential circuit of about one one-hundredth henry and at sixty cycles a displacement of potential current of approximately five minutes. Consequently, when used in connection with inductive circuits of power-factor one-tenth, the instruments indicate one and one-half per cent higher than the true watts and at one-quarter power-factor, half of one per cent. Instrument connections should be so made that the loss of the potential circuit, rather than that of the current circuit, is included in the reading, and this loss should not be deducted until after the correction factor mentioned above has been applied. Although this error on low power-factor tends to cause the instrument to read too high on lagging load, yet it is not unusual to find an instrument reading low on low power-factor and the magnitude of such error is sometimes greater than that due to self-induction of the potential circuit. This error is usually due to eddy currents in the metal parts of the instrument. It varies with the frequency, current and power-factor of the circuit and with the position of the moving coil at the time the measurement is made. No correction factor can be given, but with proper design the disturbance may be reduced to a negligible quantity. In these low power-factor measurements, care must be used not to overload the current coil of the wattmeter, for its capacity is often very much exceeded before the instrument is at one-half scale deflection. A short-circuiting switch across the current coil is recommended.

When used with either current or potential transformers, or with both, the errors mentioned in connection with voltmeters and ammeters must be allowed for, and, in addition, the phase displacement between the primary and secondary circuits of the transformers must be taken into account. The magnitude of this displacement depends principally upon the design of the transformers and the time-constant of the devices in the secondary circuits. In well-designed potential transformers, this phase displacement will not amount to more than five of six minutes at light secondary load, and the secondary potential leads the primary. As the full secondary load is approached, if the load is non-inductive, such as potential circuits of indicating instruments, the displacement may become ten minutes lagging, while if the load is mostly inductive, as for example, the potential circuits of induction meters, it may become thirty to thirty-five minutes leading. If the current being measured is non-inductive, no appreciable error is introduced by this change, but with power-factor one-half and a fully loaded potential transformer, the instrument may read one-half per cent high or one and one-half per cent low, depending on whether such load is principally non-inductive or highly inductive. With lightly loaded potential transformers this error would not amount to more than one-half per cent.

In current transformers this displacement of phase between primary and secondary current is usually greater than in the potential transformers. With one or two instruments on the secondary and full current in the primary, it may amount to thirty or forty minutes, and the secondary current leads the primary. As the primary current decreases, this angle increases. At one-quarter load it is about one degree and at one-tenth load, about one and one-half degrees. This means an error on a non-inductive load of one one-hundredth per cent at full load, one-fiftieth per cent at one-quarter load, and one-thirtieth per cent at one-tenth load, the instrument reads low. At power-factor one-half these errors become one and one-half per cent at full load, three per cent at one-quarter load and four and one-half per cent at one-tenth load, and the instrument reads high on inductive load. It is therefore evident that combinations of transformer and instrument errors may not infrequently occur in which the error of the wattmeter reading may exceed five per cent at power-factor as high as one-half and that an accuracy better than three per cent is not to be relied upon without taking all possible precaution and having at hand the correction factor for each individual piece of apparatus used. With such correction factors applied, errors greater than one to one and one-half per cent need not be expected.

TIME.

The accuracy of stop watches is generally very much overestimated. Watches with compensated balances and well-jeweled bearings are purchased. It is a poor watch which can not be adjusted to keep time with an error not greater than one minute per week. That is, as a timepiece, its error is within one hundredth part of one per cent. The balance wheel of a watch completes its excursion of approximately 250 degrees in one-fifth of a second. It is necessary for good timekeeping qualities that its motion should be free as possible and that it should be entirely disconnected from the train for the greatest possible portion of this excursion. It swings entirely free for approximately 240 degrees, during which time the train drives the hand forward one-fifth of a second division and again locks it from any movement during the 240 degrees of the balance wheel excursion. In other words, the hands of a watch are absolutely stationary during ninety-five per cent of any interval of time and it makes no difference in the movement of the stop hand, whether it is thrown in mesh at the beginning or the end of an excursion of the balance. Therefore, with a perfect timepiece, a perfect stop mechanism and absolutely no error on the part of the observer, an error of practically one beat or one-fifth second may easily occur in measuring time. In thirty-second observations, this error may amount to two-thirds per cent. When we add to this error those due to imperfect stop mechanisms, a throw of the hand in the interval between freeing it from the friction clamp and meshing it with the train, a similar throw in disconnecting from mesh and again clamping it, and the inaccuracy of the meshing itself, it is not difficult to realize that an additional error of one-half per cent may be introduced. The only precautions which can be taken are to use two stop watches, one in each hand, to practice operating the stop mechanism with as little jar as possible to the watch, to reject any observation in which the watches do not agree within two-fifths second, and to refuse absolutely any measurement covering a period of less than fifty or sixty seconds.

In conclusion permit me to express the hope that nothing in this paper may be considered as a reflection on reasonable accuracy of portable measuring instruments. I have sought only to show that laboratory accuracy may not be obtained under other than laboratory conditions, that errors of one or two per cent represent reasonable commercial accuracy and that even this may not be relied upon unless the best judgment is exercised in the selection, care and use of portable instruments. Purchase those instruments which are best adapted to the conditions under which they are to be used, place them in the custody of an experienced instrument man and give him facilities and authority in control of them which will insure their proper use.

INDUSTRIAL SECTION

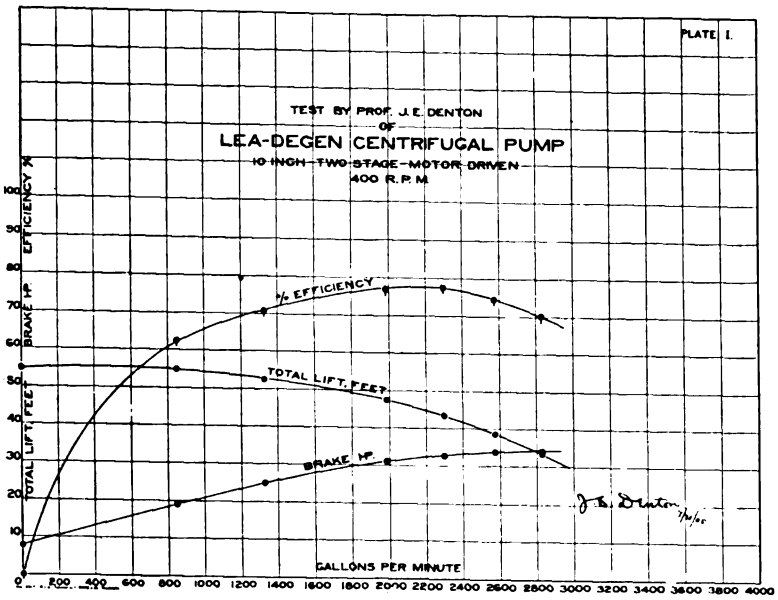
ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

The Lea-Degen High-Duty Turbine Pump.

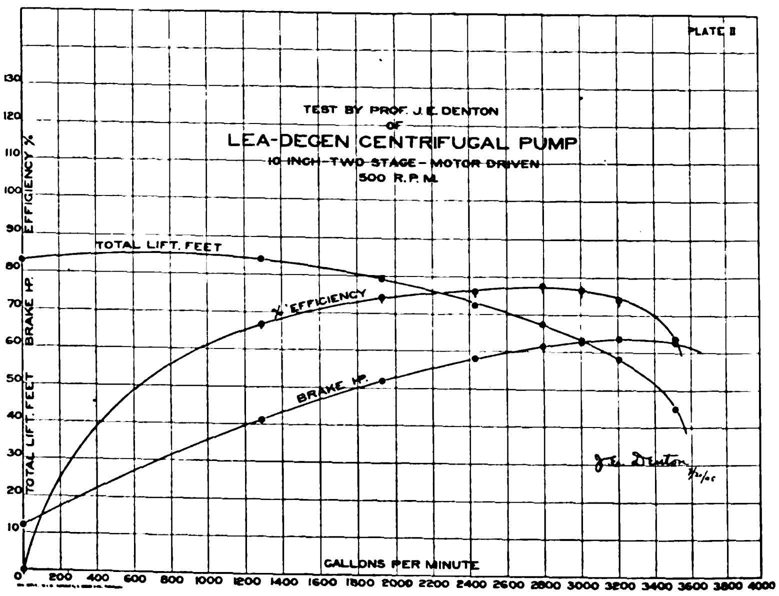
The Lea Equipment Company, 136 Liberty street, New York city, has placed on the market a motor-driven high-duty turbine pump, illustrations of which are shown herewith. The complete line of pumps is made of separate units that are designed for heads from seven to 1,000 feet or higher, and their capacities range from seventy-five gallons to 30,000 gallons per minute. The general design of the pump is indicated in the illustrations. It consists essentially of two shrouded runners or pump wheels mounted on the same shaft in a double case. The case is so proportioned that the water is drawn from the source of supply and put under pressure by the first wheel and then delivered to the suction chamber of the second wheel. The second wheel imparts to the water the same amount of energy it receives from the first wheel, thereby increasing the pressure, and then delivers the water into a spiral discharge conduit terminating in a diverging nozzle connecting with the main pipe.

The case is divided through its horizontal diameter by bolted flanges, so that its top half can be quickly freed and lifted off without disturbing either suction or discharge connections. By means of bolted circumferential divisions of the case provision is made for either using the suction and discharge end of a case together as a single-stage pump or adding as many intermediate sections as may be necessary to afford any desired pressure at any fixed speed. Additional stages can therefore be installed after a pump has been in operation, without wasting any parts of the existing case.

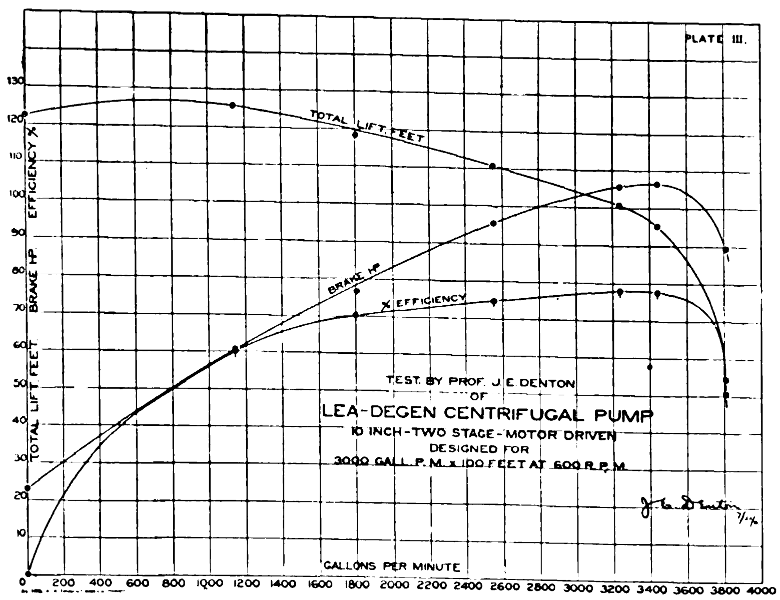
The curves herewith show the results secured under a test conducted by Professor James E. Denton, of the Stevens



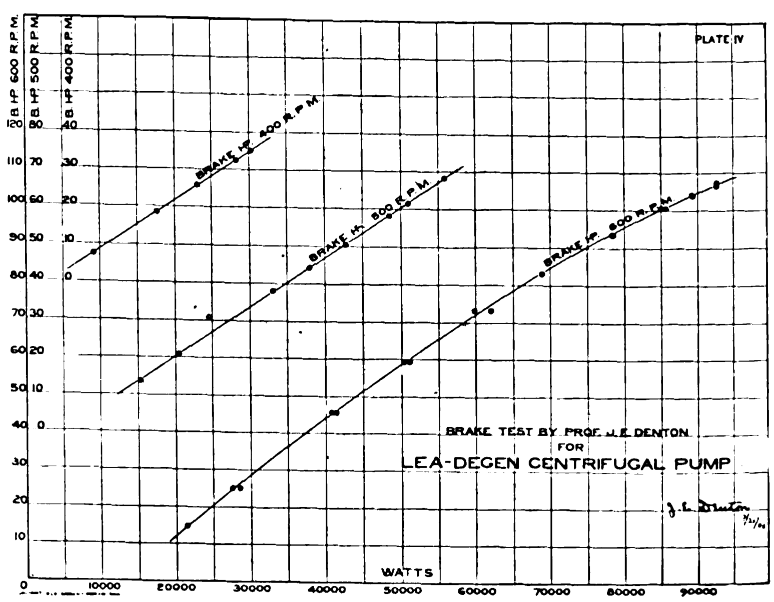
"GALLONS-LIFT" CURVE FOR 400 REVOLUTIONS PER MINUTE TURBINE PUMP.



"GALLONS-LIFT" CURVE FOR 500 REVOLUTIONS PER MINUTE TURBINE PUMP.

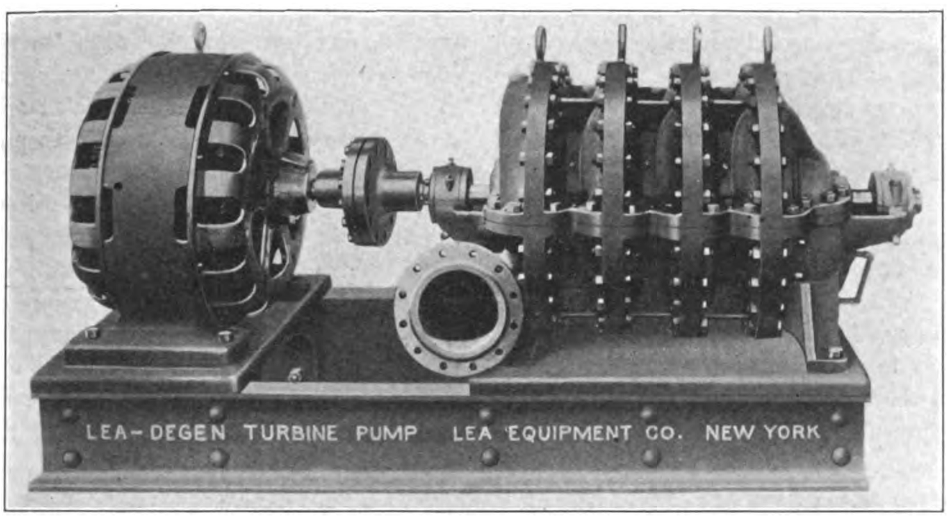


"GALLONS-LIFT" CURVE FOR 600 REVOLUTIONS PER MINUTE TURBINE PUMP.



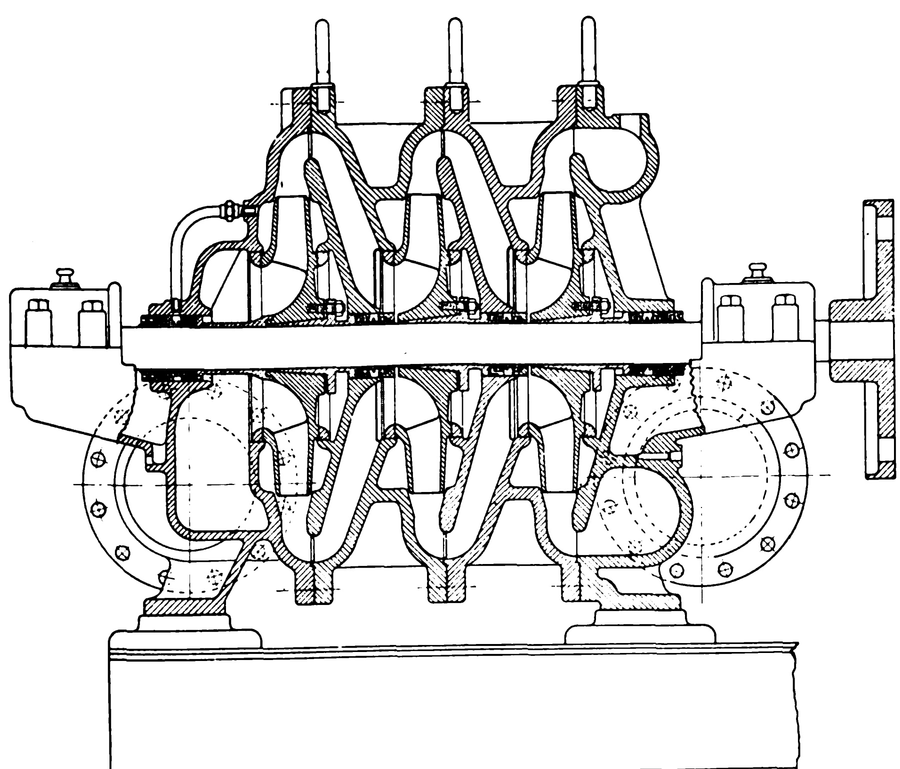
"BRAKE-HORSE-POWER-WATTS" CURVE, TURBINE PUMP.

Institute of Technology. This test was conducted on a Lea-Degen two-stage centrifugal pump driven by a 220-volt, direct-current General Electric motor. The test



The Lea-Degen Motor-Driven Turbine Pump.

shows that the pump gave the following results, under conditions of maximum efficiency: At 400 revolutions, seventy-seven per cent efficiency with a capacity of

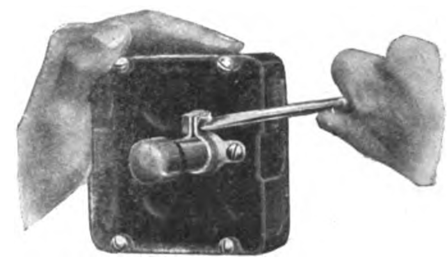


Sectional View of Two-Stage Lea-Degen Pump.

2,296 gallons under 43.6 feet lift; at 500 revolutions, 77.6 per cent efficiency with a capacity of 2,794 gallons under 67.4 feet lift; at 600 revolutions, 77.97 per cent efficiency with a capacity of 3,235 gallons under 100.7 feet lift. In round numbers, therefore, the capacity at maximum efficiency is directly proportional to the revolutions, and the lift, or head, is proportional to the square of the revolutions. At each speed the efficiency averaged more than seventy-six per cent over a range of 600 gallons of capacity for the two lower speeds, and 900 gallons at the highest speed, the head remaining nearly constant.

A Clamp for Ceiling Outlet Boxes.

A neat little device for fastening ceiling outlet boxes to the dummy or gas pipe has recently been put on the market which bids fair to eliminate many of the difficulties experienced in installing boxes in the old way.



Clamp for Ceiling Outlet Boxes.

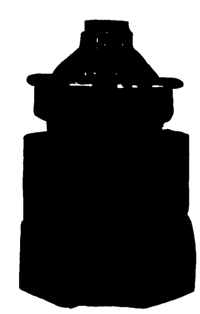
The outlet box is held firmly in position at right angles to the pipe, so that there is no chance of breaking the plaster by swaying fixtures. The opening where the pipe passes through the box is also filled up, thus preventing flames from being drawn up through it in case of fire being started by a short-circuit or loose contact.

The clamp is made in two sizes, three-eighths-inch and one-half-inch, with two lugs for ordinary purposes, and three lugs for heavier work, such as in fire-proof buildings.

It is manufactured by the Federal Electric Company, of Chicago, and is approved by the Underwriters' Laboratories.

The Lang "Quixet" Floor Box.

The accompanying illustration shows the Lang "Quixet" floor box, made by the J. Lang Electric Company, 116 Lincoln



The Lang "Quixet" Floor Box.

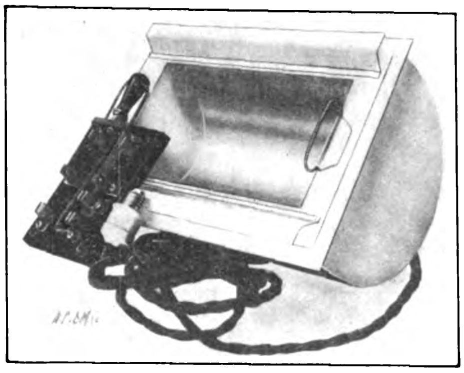
street, Chicago, Ill. This box is designed to overcome all of those disadvantages with floor boxes which have proven expensive and annoying in their use. In installing this box it is not necessary to cut out or adjust the floor in any way. The box adjusts itself to the floor without the use of screws, gaskets or other devices. It is smaller than the ordinary floor box, and will fit into installations where the ordinary box would not be permissible.

Electrically Heated Chocolate Warmer.

Among the industrial applications which are being successfully met with electrically heated devices, the confectioner's chocolate warmer or dipping pan is an example. The Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa., is making the Hadaway electrically heated dipping pan, an illustration of which is shown herewith, and which is being used by a large number of prominent candy manufacturers in this country and abroad.

The pan consumes about the same amount of current as a sixteen-candle-power lamp. The heater is placed in operation by closing a switch. A further advantage of the Hadaway electrically heated chocolate warmer for refrigerated rooms arises from the fact that the dry, flameless heat results in a great reduction in the expense for cooling.

Hadaway electrically heated chocolate warmers are usually made with a high and low heat, the change from one to



ELECTRICALLY HEATED CHOCOLATE WARMER.

the other being made by a small switch. The low heat is sufficient to maintain the chocolate at the proper working consistency, while the high heat is designed to bring the chocolate to the working temperature in a short time. When desired, warmers can be supplied having only the low heat. These are used in connection with chocolate melters, but it occasionally happens that the chocolate cools in the pan, causing loss of time and delay in the work. This can be avoided by using the two-heat apparatus with which the high heat will be available whenever required.

The warmer is made in two standard sizes. The large size is fourteen and one-quarter inches long, seven and five-eighths inches wide and six inches deep. The small size is twelve inches long, six and one-quarter inches wide and five inches deep. These dimensions refer to the pan in which the chocolate is placed. The heating element is upon the outside of a receptacle in which the chocolate pan is placed and is hermetically sealed in by an outer jacket. The heater and wires are shielded so that accidental contact with them can not be made and the operators are absolutely protected from all danger of an electric shock.

The warmers can be set in the top of a table and connected with the heat-control switch by the engineer on the premises according to a simple wiring diagram sent out with the apparatus. The chocolate warmer can be connected to a lamp socket, but permanent wiring is recommended for factories. The entire method of mounting them can be arranged to suit the individual preference of the purchasers. The dipping pans are shipped all ready to place in a table and connect up, and the tables for mounting the pans can be procured or made by the purchaser without difficulty.

Electrical Supplies for the Navy Department.

The Bureau of Supplies and Accounts will open bids in Washington, D. C., on October 20 for the following electrical material: Sixteen hundred and fifty incandescent lamps for delivery at Annapolis, Md.; twelve starting panels for delivery at Norfolk, Va.

Bids will be opened on October 27 for 100 dry batteries, 3,000 wood blocks, nine dozen brushes, 20,000 feet lighting cable, 12,000 carbons, 4,000 feet silk-covered cord, miscellaneous fittings, miscellaneous inner and outer globes, 3,000 wire lamp guards, 200 insulators, 19,100 incandescent lamps, four direct-current motors, 2,300 porcelain receptacles, 35,000 feet rubber-covered wire, and 8,000 feet twisted wire, for delivery at Brooklyn, N. Y.; one Wheatstone bridge, six desk-type fans, miscellaneous electrical supplies for delivery at Annapolis, Md.; miscellaneous electrical supplies for delivery at Norfolk, Va.

New Holophane Reflectors for Tungsten Lamps.

The Holophane Company, New York city, has completed the designs for an entirely new line of reflectors for tungsten lamps.

The new tungsten reflectors are of three types which will be known to the trade as the "Extensive," "Intensive" and "Focusing" types. In appearance all are similar to the original "bowl type" Holophane reflectors designed for Gem lamps, but each of the three new types above named gives a distinctive distribution of light. In the preliminary engineering work connected with these new types, the engineering department, Holophane Company was ably assisted by A. J. Sweet, of the Westinghouse company.

In the designing of the reflectors an entirely new principle was evolved—that of the "merging prism." As is well known, Holophane reflectors having a continuous prism from the collar to the edge lose considerably in efficiency, owing to the fact that the prism is much larger at the bottom than at the neck. To prevent this the Holophane Company designed what is known as the "equal prism" reflectors, in which prisms of practically equal size are run in several banks from neck to top. In the new types, instead of an abrupt step between the banks of prisms the several banks are merged one into the other, which not only adds greatly to the beauty of the reflectors but at the same time gives the maximum of efficiency.

The new "merging prism" reflectors are made for forty, sixty and 100-watt tungsten lamps, three types, as above de-

NEW HOLOPHANE REFLECTOR.

scribed, for each size of lamp. This makes a very compact line and one which is uniform in appearance.

A new Holophane bulletin descriptive of this line of high-efficiency reflectors is now in press. In addition to technical description, photometric curves, etc., this bulletin will contain a few simple rules by following which even a novice may be sure of selecting proper size of lamps and correct Holophane reflector and of spacing these rightly in any ordinary lighting installation. The new "flux of light" method of calculating illumination, it is stated, enables the Holophane Company's engineers to reduce the salient features of practical illuminating engineers to a few simple "rules of thumb" which are applicable wherever the installation is not complicated by æsthetic or architectural difficulties or restriction.

The new line will be handled not alone by the Holophane Company, but also by the General Electric Company, Westinghouse Electric and Manufacturing Company, Franklin Electric Manufacturing Company and the companies comprising the National Electric Lamp Association.

Current Electrical News

DOMESTIC AND EXPORT.

ARKANSAS INTERURBAN PLANNED—A project to build a third-rail interurban line from Little Rock south to Sheridan, branching out from that place to Hot Springs and Pine Bluff, all in Arkansas, the entire road to be built at an actual cost of $2,700,000, has been planned by the Central Arkansas Electric Railway Company, of Pine Bluff, and is now being considered, it is stated, by Chicago capitalists, who will probably reach a decision in regard to the project by the first of the next year. Preliminary surveys and plans for the railroad have already been made. Sheridan is thirty or thirty-five miles south of Little Rock. Hot Springs is about forty-five miles west of Sheridan and Pine Bluff about thirty miles east of the same place.. A. M. Van Auken is chief engineer of the company.

TELEPHONE COMPANIES UNITE—At a meeting of the stockholders of the United States Telephone Company, the Cuyahoga Telephone Company, of Cleveland, Ohio, and the Citizens' Telephone Company, of Columbus, Ohio, the three companies were merged. The new company, which has not been named, will act as an operating company with a capitalization of between $5,000,000 and $10,000,000 and will take over the three independent companies on a lease for 999 years. Other Ohio independent companies will, it is stated, be added from time to time. The merger places under the control of the operating company over fifty per cent of the independent telephones and about 75,000 of the 325,000 telephones in the state of Ohio. The United States company has extensive long-distance lines in Ohio and adjoining states.

MEXICAN ELECTRICAL NOTES—The Guanajuato Power and Electric Company has arranged for the construction of a new line eighty-five miles in length to be used as a reserve line in case of accident. The wire for this new line will be strung on steel towers beginning at Penjama and terminating at the station at Guanajuato. There will be substations every twelve miles. Work will be begun at once. The Atotonilco Light and Power Company, a concern recently organized by Guadalajara men to furnish current for light and power in the town of Atotonilco, the centre of the orange district of Jalisco, has placed an order with Siemens-Schuckertwerke, of Berlin, for hydroelectric machinery, transmission lines and substation equipment. The value of the order is $14,000. The Guadalajara company will utilize a waterfall near the town.

OMAHA MEN INCORPORATE INTERURBAN COMPANY—The Nebraska Traction and Power Company, of Omaha, is the name of a new corporation that has filed articles with the secretary of state under the interurban law passed two years ago. It has an authorized capital stock of $2,000,000 and the incorporators are: Mel Uhl, N. P. Dodge, Jr.; William D. Crist, F. A. Howard and J. F. Emmert, all of Omaha. The company proposes to build a line from South Omaha in a westerly direction through Douglas County to the town of Ralston, thence in a southerly direction through Sarpy County and in a northerly direction from Ralston through the counties of Douglas, Dodge, Washington, Burt, Cuming, Thurston and Dakota, Neb. It is to be either a single or double-track road, and operated by electricity or any other motive power. The company proposes to operate telephone or telegraph lines and to transmit power, light and heat for itself or other persons, and to carry passengers, baggage, express and mail. The $2,000,000 capital stock is to be divided into shares of $100 each, 15,000 shares to be preferred and 5,000 common.

NEW ELECTRIC COMPANY FILES ARTICLES—The Des Moines (Iowa) Electric Company has filed articles of incorporation. The charter of the company gives it the right to own lighting plants and all appurtenances and property in connection therewith and railways. Its capital stock is $5,000,000, of which $3,500,000 is common and the rest preferred. Of the common stock fourteen shares, representing $1,400 par value, has been issued. None of the preferred has been issued. The officers of the company are: J. Berry, president and treasurer; Lewis A. Burleigh, clerk; Joseph Williamson, Ernest L. McLean, Walter M. Sanborn, E. M. Leavitt and M. M. Spinney, with the officers named, forming the board of directors. All of the officers except Mr. Leavitt of the board live at Augusta, Me. He lives at Winthrop. Five of the common stock shares of the company are held in New York city, six at Augusta, Me., and one each at Ridgewood, N. J., at Brooklyn, and at Winthrop, Me.. The purpose of the new organization, which now has a right to do business in Iowa, is to take over the Edison Light Company, of Des Moines. The Edison Light Company operates under the laws of the state of Iowa.

IDAHO-OREGON LIGHT AND POWER COMPANY—All business of the subsidiary companies of the Idaho-Oregon Light and Power Company will hereafter be transacted in the name of the owning company, recently formed for the purpose of perfecting a merger. The Oregon-Idaho company, which is incorporated with a capital stock of several million dollars, and in which the Mainland brothers, of Oshkosh, Wis., are interested, has now absorbed the Capital Electric Light, Motor and Gas Company, the Boisé-Payette River Electric Power Company, the Electric Power Company, of Boisé; the Interstate Light and Power Company, of Meridan, and the Emmett Electric Light Company, of Emmett. This company is at present furnishing light and power to Boisé, South Boisé, Pearl, Horseshoe Bend, Neal mining district, Meridian, Emmett and Ontario, Ore., and is constructing lines to New Plymouth and Weiser. Power is supplied from the Horseshoe Bend plant on the Payette River, the Barber plant on the Boisé River and a smaller plant on the Ridenbaugh canal in South Boisé, with a total capacity of 5,000 horse-power. The company is building a large power plant on the Snake River, sixty miles north of Huntington, which will have a capacity of 30,000 horse-power. One hundred and thirty miles of transmission line is now supplying the district south and east of Weiser, Ida., and some 200 additional miles will be built next year.

NEW MANUFACTURING COMPANIES.

RICHMOND, VA.—The corporation commission has issued a charter to the Southern Electric and Manufacturing Corporation, Richmond, with B. B. Brauer, president; E. D. Moore, vice-president, and J. W. Church, secretary and treasurer—all of Richmond. The maximum capital is $50,000; minimum, $25,000. The company will manufacture and sell the Brauer automatic time switch.

SEATTLE, WASH.—The United Wireless Telegraph Company has purchased the factory of the Nelson Metal Specialties Company. It will be taken over by the operating department of the company, headed by C. C. Galbraith, and work will begin at once in the manufacture of wireless apparatus for use on the Pacific Coast. The first wireless instruments to be turned out will be for a demonstrating wireless station at the Spokane fair.

SALINA, KAN.—The Anderson Electric and Manufacturing Company has been incorporated with a capital of $200,000 to manufacture the inventions of John Anderson, of Salina, Kan., including the Anderson lockout system for telephone circuits and other telephonic appliances and improvements. The officers are: R. T. Blair, of Emporia, Kan., president; C. E. Carlson, of McPherson, Kan., vice-president; R. G. Henderson, of McPherson, secretary, and J. K. Bremyer, of McPherson, treasurer. The temporary headquarters of the company are at Salina.

DATES AHEAD.

American Society of Municipal Improvements. Annual meeting, Atlantic City, N. J., October 20-23.

American Electrochemical Society. Fall meeting, New York city, October 30-31.

Association of Car-Lighting Engineers. First annual meeting, Chicago, Ill., November 18.

National Society for the Promotion of Industrial Education. Annual meeting, Atlanta, Ga., November 19-21.

American Roentgen Ray Society. Annual meeting, New York city, December 28-30.

ELECTRIC LIGHTING.

SHERMAN, TEX.—The city has voted on the issuance of $16,000 light-betterment bonds.

OTTAWA, ILL.—Ground has been broken for the interurban between Streator and Grand Ridge.

GADSDEN, ALA.—The Sand Mountain Electric Company has been organized to install an electric light plant at Albertville.

WAVERLY, IOWA—The municipal light and water plants at Waverly were destroyed by fire on September 22, involving a loss of $50,000.

NASHVILLE, TENN.—The Chattanooga Electric Company, chartered under the laws of Maine with $3,000,000 capital, has filed its charter.

FLORESVILLE, TEX.—The city council has granted permission to Dr. Largen, of San Antonio, to establish an electric light plant at Floresville.

WINCHENDON, MASS.—The town selectmen have granted the Connecticut River Transmission Company permission to erect towers for the support of high-tension wires.

EL PASO, TEX.—Richard Caples and W. B. Latta have been granted a franchise to build an electric line through El Paso County. The grantees must build at least ten miles of road in two years.

SPRINGFIELD, ILL.—The Springfield, Clear Lake & Rochester Interurban Railway Company has been given the right to operate cars over the lines of the Springfield Consolidated Railway Company.

DOUGLASVILLE, GA.—M. L. Hathcock has purchased the old Arnold mill property and it is said will build a dam and generate sufficient power to operate an electric plant to supply nearby towns.

BALTIMORE, MD.—At the annual meeting of the Consolidated Gas, Electric Light and Power Company, of Baltimore, the seventeen retiring directors were re-elected, with the addition of W. H. Cassell.

LORAIN, OHIO—The service board has decided to employ F. C. Werk, a Cleveland contractor and engineer, to submit preliminary estimates on a municipal lighting plant for the city as requested by the council.

KENNETT, CAL.—The new power line of the Northern California Power Company, directly from the Volta power plant to Kennett, a distance of forty miles, is in operation. The line will carry 60,000 volts.

STEVENSON, ALA.—The board of aldermen has granted an electric light franchise to Fred A. Howe, of Huntsville. The business men are subscribing liberally for lights, both in their homes and business houses.

SEATTLE, WASH.—The finance committee of the city council has authorized Superintendent L. B. Youngs, of the light and water department, to complete the present extension of the lighting system from Cedar Lake to the city.

FREDERICKSBURG, VA.—Work on the new steel dam of the Fredericksburg Power Company on the Rappahannock River, above this city, is progressing rapidly. The first section of the dam will be completed within the next thirty days.

MONTGOMERY, ALA.—General Manager R. L. Pultz, of the Birmingham & Gulf Navigation Company, says that it is the intention of the company to build electric lines from Gadsden to Birmingham and Tuscaloosa in a short time.

WOONSOCKET, R. I.—The Woonsocket Realty Company has sold to the Woonsocket Electric Machine and Power Company valuable water rights on the old Ray Mill property. The company will use the power for operating its No. 2 station.

MILLEN, GA.—J. B. McCrary & Company, of Atlanta, have been awarded the contract for a lighting plant and water works for Millen. W. O. Lumpkin will have charge of construction and will commence work as soon as material can be had.

OGDEN, UTAH—The preliminary work on the proposed power plant in South Fork cañon has been started. It is the purpose of the builders to put in a pipe-line and a plant that will generate 10,000 horse-power which will be brought to this city by a pole-line.

PONTIAC, MICH.—The title to the Clinton River Power Company at Amy has passed into the hands of William H. Osmun. Mr. Osmun says he expects to utilize the Clinton River to secure 1,000 horse-power. Electric light and power will be furnished to Pontiac.

DURHAM, N. C.—The East Durham Cotton Mills announce that as soon as the installation of the new machinery can be made the mills will be run by electric power. Two of the engines with eight boilers will be removed for the erection of new boiler and engine houses. The change will involve an outlay of $75,000 or more.

LEBANON, PA.—A meeting of local capitalists was held in this city for the organization of a trolley company. A line will be built from Womelsdorf, Berks County, to Campbelltown, Lebanon County. A committee was appointed to secure a charter and to have surveys made. Most of the rights of way of the company have been secured.

ASHBURN, GA.—Bonds to the amount of $50,000, issued by the city of Ashburn, for the purpose of putting in electric lights and waterworks, have been sold and the contract let for the work, J. B. McCrary, of Atlanta, being the successful bidder. The work will be commenced as soon as the necessary preparations can be made.

ALBION, N. Y.—At a meeting of the village board of trustees a resolution was passed entering into a contract with the Albion Power Company to furnish the village with sixty-eight street arc lamps at $70 each. The company has expended $20,000 in improving its plant. Hereafter this village will receive an all-night service.

SACRAMENTO, CAL.—Work is progressing on the new dam of the Folsom Power Company on South Silver Creek in El Dorado County, and a force of men is employed clearing the right of way which has been secured over state and private lands. It is estimated that the new plant will give the company an additional 10,000 horse-power. The new plant will be installed within the next few months.

MONTPELIER, VT.—The Molly Falls Electric Light and Power Company has purchased all the right and interest which the late Perrin P. Kellogg, of Whitefield, N. H., had in the Molly Falls water power under a lease and contract given to Mr. Kellogg in 1903. The company leased its water rights and privileges for a period of ninety-nine years at $900 a year, reserving 400-horse-power with which to furnish lights to Cabot, Plainfield, Marshfield and North Montpelier.

COLUMBUS, OHIO—At meetings of the board of directors of the several companies concerned, held in Springfield, the merger of the People's Light, Heat and Power Company and the Home Light and Power Company, of Springfield, under the new name of the Springfield Light, Heat and Power Company was completed. Officers of the new company were provided for and the first payment of $50,000 made on the properties of the Home company. The new company will issue $500,000 of bonds, to be sold at ninety, the proceeds of which will be used to purchase the Home plant and retire the outstanding bonds of the People's company. An exchange of stock will be made for that of the People's company now outstanding. The capitalization of the new company is $1,000,000.

MISSOULA, MONT.—The Idaho Railway and Navigation Company has been incorporated in Washington with a nominal capital of $100,000 to build an electric line from Dead Man's Creek, in the northern part of Garfield County, through Asotin County and around the Blue Mountain range to the Seven Devils mining district, in Idaho, seventy-seven miles. The incorporators are: D. Van Arsdale, president; Samuel L. Tate, secretary; C. W. Hadley, general manager; M. Wood, engineer; Lester P. Edge and Fred Larson. Eleven directors and a council of five will be elected in November, at which time it is expected to have twenty miles of line completed. The single-phase system will be installed. The power-house, to be erected on Snake River, and the distributing stations, will cost $64,000, while the line will cost $40,000 a mile. The line will tap coal, cement and mineral deposits, and also run through agricultural, orchard and stock districts, not now served by railroads.

PERSONAL MENTION.

MR. PATRICK B. DELANY has been awarded the Elliott-Cresson gold medal for his invention of a system of rapid telegraphy.

MR. ALLEN L. HASSE has resigned as sales manager of the Pierce Company, and joined forces with the Harvard Electric Company, Chicago, Ill., as general sales manager.

MR. G. L. CONKLIN, who has been assistant manager of the Mankato Electric Traction Company, of Mankato, Minn., for some time, has been made general manager of the company, succeeding H. E. Hance, who will become connected with a proposed electric road to St. Peter.

MR. FRED W. GODFREY, for the past six years representing the Bryan-Marsh Company, and manager of the Cincinnati, Ohio, branch for the past two years, has organized the Godfrey Sales Company, with an office in the Perin Building, Cincinnati. Mr. Godfrey will continue to represent the Bryan-Marsh Company, as well as the Ambos-Cudmore Company, of Cleveland, Ohio. Among the lines represented by the Godfrey Sales Company are Bryan-Marsh Company lamps, Duncan wattmeters, Duncan transformers, Wheeler reflectors, Weston instruments, Bristol recording instruments. Aladdin specialties, Detroit rubber-covered wire, Hartford automatic time switches, Condit circuit-breakers and oil switches.

NEW PUBLICATIONS.

CALCULATIONS FOR POWER DISTRIBUTION—The Association Amicle des Anciens Elèves has reprinted in pamphlet form the treatise by J. H. Jacobsen, entitled "Calcul Electrique et Mécanique des Distributions d'Energie."

DEPARTMENT OF EDUCATION, CITY OF NEW YORK—The Department of Education of the city of New York has published its announcement of public lectures to be given in Manhattan and The Bronx for the October-December course. The department has also published the annual report of the supervisor of lectures of the board.

THE BROOKLYN INSTITUTE OF ARTS AND SCIENCES—The Brooklyn Institute of Arts and Sciences has published its prospectus for 1908-1909. In science the department of electricity will conduct a series of illustrated lectures on electrical engineering on Thursday evenings. Professor Samuel Sheldon is president, and Hubert S. Wynkoop is secretary, of the department. The department of engineering will conduct a series of illustrated lectures on engineering on the third Thursday evening of each month. Nelson P. Lewis is president, and Arthur S. Tuttle is secretary, of the department. The central office of the institute is now established in the Academy of Music on Lafayette avenue.

NEW INCORPORATIONS.

AUSTIN, TEX.—The Godley Independent Telephone Company, Godley, Johnson County. $3,200. Incorporators: B. B. Robinson, J. A. Dalton, C. D. Odom, John R. Beaver.

MADISON, WIS.—Cady Telephone Company, village of Wilson, St. Croix County. $5,000. Incorporators: S. L. Pickett, G. W. La Pointe, Jr., Martin D. Erickson, Frank Smith, David Cushing and Peter Simonson.

MOSCOW, IOWA—E. S. Johnson Company, of Davenport, Iowa, $100,000. To do general construction work, operate and build manufacturing plants, deal in stocks and real estate and build and operate steam and interurban railways. Officers: E. S. Johnson, president; John C. Sessor, vice-president, and Julius E. Burmeister, secretary and treasurer.

HARRISBURG, PA.—Lost Creek Valley Rural Telephone Company. $5,000. To build a line from Mifflin to Selins Grove and Middleburg; from Mifflin to Blain, Newport, Millerstown and New Bloomsfield, and from Mifflin to Liverpool. Incorporators: A. J. Beyers, Mifflin; H. J., J. H. and Leo Shallenberger, and A. W. Herr, McAllisterville; J. O. Smith and J. H. Carney, Bunkertown.

ELECTRICAL SECURITIES.

The market suffered during the week, by reflection from foreign financial centres, from the disturbances created by the boiling over of the Balkan cauldron. For a few days even the political situation here was overshadowed, but when the first-mentioned matters were analyzed and discussed it remained to be seen that the latter was still the predominating factor in stock market influences. Industrial betterment seems to be more generally recognized, and with the better prices than usual prevailing and posted for futures it appears as if our agriculturists would be richer by some billion of dollars when the season's crops shall have been harvested and disposed of.

Dividends have been declared upon the following electrical securities: Electric Bond and Share Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable November 1. Commonwealth Edison Company; quarterly dividend of 1½ per cent, payable November 2 to stock of record October 20. The rate previously was 1¼ per cent quarterly. Central District and Printing Telegraph Company; regular quarterly dividend of 2 per cent, payable October 31 to stock of record October 24. American Light and Traction Company; regular quarterly dividends of 1½ per cent on the preferred stock and 1¾ per cent on the common stock, both payable November 2. Books close October 21 and reopen November 2. Mexican Telephone and Telegraph Company; regular semi-annual dividend of 2½ per cent, payable November 2 to stock of record October 16. Edison Electric Illuminating Company of Boston; regular quarterly dividend of 2½ per cent, payable November 2 to stock of record October 15. East St. Louis & Suburban Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable November 2 to stock of record October 15. Columbus Railway Company; regular quarterly dividend of 1¼ per cent on the preferred stock, payable November 2 to stock of record October 15.

ELECTRICAL SECURITIES FOR THE WEEK ENDED OCTOBER 10.

New York:	*Closing.*
Allis-Chalmers common	11¼
Allis-Chalmers preferred	35½

The annual meeting of the Manhattan Railway Company will be held at 195 Broadway, New York city, on November 11.

Boston:	*Closing.*
American Telephone and Telegraph	126¾
Edison Electric Illuminating	225
Massachusetts Electric	51
New England Telephone	119½
Western Telephone and Telegraph preferred	75

The number of stockholders of the American Telephone and Telegraph Company now amounts to better than 25,500, an increase of over 2,000 since the beginning of the year. This is a gain of 8 per cent in the nine months. Less than two years ago the American Telephone Company had barely 18,000 stockholders, so that there has been an average yearly increase of over 3,500 names in the past two years.

Philadelphia:	*Closing.*

For September the Chicago Telephone Company gained 2,095 telephones, making a gain for nine months of 21,443, and a total in service of 175,075.

The annual meeting of the Commonwealth Edison Company will be held November 9. Proxies run to Robert T. Lincoln, Samuel Insull and William G. Beale.

ELECTRIC RAILWAYS.

WACO, TEX.—The survey of the proposed Waco, Temple & Marlin interurban has been begun out of Temple. Construction will start in a few weeks.

MILWAUKEE, WIS.—The first through electric car over the Chicago & Milwaukee Electric road, from Evanston to Milwaukee, arrived at the southern city limits of Milwaukee on September 30.

MONTGOMERY, ALA.—It is understood that in a short time the Montgomery Traction Company will begin the work of generally extending its lines. At a meeting of the directors, held in Philadelphia, it was decided to take up the matter.

WEATHERFORD, TEX.—Mayor Moseley announces the completion of the Weatherford interurban survey subscriptions. The expenses to survey the line to Mineral Wells were guaranteed by Fort Worth, Mineral Wells and Weatherford. The work will cost $3,500.

SPOKANE, WASH.—Announcement is made that about the middle of December the new Brookville-Puyallup branch of the Puget Sound Electric Railway will be opened for traffic. The completion of this line of electric railroad will enable the people of the Puyallup Valley to come direct to this city.

DOWAGIAC, MICH.—Articles of incorporation have been filed for the Dowagiac Railway Company, the incorporators being C. K. Minary, H. S. Grey and Henry Mason, of Benton Harbor, and the capital stock being $200,000. These gentlemen are identified with the Benton Harbor & St. Joseph Street Railway and Power Company, and it is their purpose to extend the electric line from Eau Claire to Dowagiac.

BUFFALO, N. Y.—The last link connecting Erie with Buffalo by trolley will be completed by January 1, 1909, according to General Manager Calisch, of the Buffalo & Lake Erie Traction Company. The only gap now remaining is at Westfield, and this will soon be closed under action taken by the village taxpayers, who have voted $35,000 toward the expense of a viaduct to connect the hills on the opposite sides of Chautauqua Creek.

SPRINGFIELD, ILL.—The construction of the interurban line from Springfield to Quincy by way of Petersburg is an assured fact, according to the officials of the Springfield-Rochester line, who have charge of the proposed new line. Practically all of the right of way has been secured, and grading from the entrance of the Zoo park west has been carried a considerable distance. The extension of the city street railway line to the Zoo park next spring will assure an entrance into the city for the new line.

GREELEY, COL.—At a meeting of the directors of the Burlington Interurban Railway Company, which is building a line from Hudson, on the Burlington, to Greeley, Pleasant Valley, Ault and Fort Collins, the resignation of F. O. Olson as president was accepted and John P. Klug, one of the wealthiest stockmen and land owners in Weld County, was elected to the vacancy. C. I. Moore, a merchant of Greeley, was elected treasurer. All surveys are made and grading is expected to be begun in a few days.

GUTHRIE, OKLA.—A charter has been issued by the secretary of state to the Oklahoma, Kansas & Missouri Interurban Railway Company, of Miami, with $200,000 capital stock. The company proposes to build an interurban line from Miami through Hattonville and Lincolnville to Baxter Springs, Kan., twenty-two miles, at an estimated cost of $20,000 per mile. The proposed line goes through the heart of the Miami-Baxter zinc field and proposes to haul ore as well as passengers. The incorporators are: Franklin Smith, of Joplin, Mo.; F. O. Freeman, R. H. Holton, John Hall and D. W. Cooter, of Miami.

BALTIMORE, MD.—Work on the new line of the Baltimore, Halethorpe & Elkridge Electric Railway is being pushed, and it is probable that cars will be in operation over the route early in December. The portion of the road now in course of construction reaches from the terminus of the Wilkens avenue car line to Halethorpe, a distance of three and a half miles. The line branches off from Wilkens avenue and runs almost parallel with the Pennsylvania tracks to Halethorpe. The road is being built over a private right of way, and the development will be carried only to Halethorpe for the present. The total cost of the line to Halethorpe will be about $125,000, and when completed it will be operated by the United Railways.

STOCKTON, CAL.—The electric road between Stockton and Modesto will be commenced at an early date, the financing of the road having been completed by Morris L. Brackett, of New York. Surveyors are now in the field, running the first lines between the two cities. It is proposed to build the road from the water front in Stockton out Lincoln street alongside the French Camp toll road through French Camp, Manteca, Ripon and on to Modesto. The South San Joaquin Improvement Company some weeks ago closed up the rights of way with the farmers on the understanding that they were to be transferred to the first corporation or firm that would build the road. The company turned over these rights of way to Brackett, who interested $500,000 capital.

INDUSTRIAL ITEMS.

THE BIRD-ARCHER COMPANY, New York city, has published a bulletin devoted to boiler troubles and their prevention.

STANLEY & PATTERSON, INCORPORATED, 23 Murray street, New York city, is distributing a folder calling attention to the advantages of Marshall fuse plugs.

THE RAIL JOINT COMPANY, New York city, announces that at the close of September business the total output of its base-supporting rail joints amounted to over 50,000 miles equipped during the past fourteen years.

THE FRANKLIN ELECTRIC MANUFACTURING COMPANY, Hartford, Ct. has published some interesting information in its bulletin No. 7, concerning the Franklin tungsten lamp. Copies of this bulletin will be furnished to those interested upon request.

THE HILL CLUTCH COMPANY, Cleveland, Ohio, manufacturer of power-transmitting, elevating, conveying and cement machinery, has issued a catalogue devoted to its collar oiling bearing. Copies of this catalogue will be furnished to those interested upon request.

THE TRUMBULL ELECTRIC MANUFACTURING COMPANY, Plainville, Ct., in the October issue of "Trumbull Cheer," gives some interesting information concerning the manufacture of switch clips, and illustrates the Trumbull type "A" switch for 4,000 amperes, 250 volts.

THE NERNST LAMP COMPANY, Pittsburg, Pa., has issued bulletin B, devoted to a description and illustrations of the Westinghouse Nernst multiple-glower lamps. These new types of Nernst lamps have attracted a great deal of attention, and the data contained in this bulletin will be found of value by all those interested in problems of illumination.

THE TAUNTON-NEW BEDFORD COPPER COMPANY, Taunton, Mass., has purchased the manufacturing interests of the W. S. Hill Electric Company, of New Bedford, Mass. The Hill company will become the electrical department of the Taunton-New Bedford Copper Company, and the Hill factory at New Bedford will be used until new quarters are prepared in Taunton. Charles S. Mendell, formerly treasurer and general manager of the W. S. Hill Electric Company, will be manager of the electrical department.

THE CONSOLIDATED SUPPLY COMPANY, 321 Dearborn street, Chicago, Ill., has issued its loose-leaf catalogue No. 15. In distributing this catalogue the company calls especial attention to the patented metal car roof which has just been placed on the market after having been tested out on a car for the past five years. The roof has special features fully covered by letters patent. The company is also calling attention to a new malleable tie plate which has had considerable sale, and on which patent is now pending.

THE WHEELER CONDENSER AND ENGINEERING COMPANY, Carteret, N. J., manufacturer of the well-known Wheeler surface, jet and barometric condensers and Wheeler centrifugal pumps and water-cooling towers, announces that Harry Pennington, of the Lumbermen's National Bank Building, Houston, Tex., has been appointed its agent for Texas. Mr. Pennington has been engaged in the practice of mechanical engineering in Houston for a number of years, and has been identified with many of the large enterprises in that section. He is at present consulting engineer for the Galveston waterworks, engineer for Houston and Fort Bend counties, president of the Southwestern Engineers' and Architects' clubs, and chief engineer of the state of Texas.

THE GENERAL ELECTRIC COMPANY, Schenectady, N. Y., has published an attractive bulletin entitled "Steady *versus* Unsteady Voltage." This bulletin, No. 4,619, refers particularly to the use of automatic feeder regulators for incandescent lighting on alternating-current systems. Bulletin No. 4,622 is devoted to a description and illustrations of polyphase maximum-watt indicators, and bulletin No. 4,616 contains a detailed description of high-voltage type H transformers. An attractive booklet, descriptive of the General Electric "Multi-catch" socket has been issued, and bulletin No. 4,618 describes the company's new form PB polyphase generator for use in small power plants and isolated lighting plants where rapidly increasing inductive loads and low power-factors are encountered.

Record of Electrical Patents.

Week of October 6.

900,165. PROGRESSIVE CUTOUT MECHANISM. Jay H. Hall, New York, N. Y., assignor to the Electric Controller and Supply Company, Cleveland, Ohio. Filed March 18, 1908. Means are provided for rendering the cutout driving member inoperative for a predetermined travel of the driving mechanism after each cutout operation.

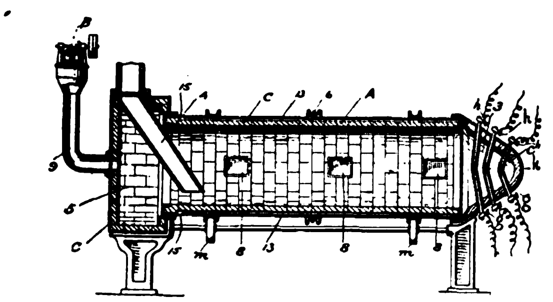
900,169. APPARATUS FOR ELECTROPLATING METAL SHEETS. Henry L. Hollis, Chicago, Ill. Filed August 1, 1907. Means are provided for conveying sheets of metal vertically from one end of the vat to the other.

900,192. ELECTRIC FURNACE. Robert McKnight, Pittsburg, Pa. Filed August 28, 1906. A rotating tubular furnace is heated by passing a draft through an electrically heated firebox.

900,207. ELECTRIC FURNACE. James H. Reid, Cornwall, Ontario, Canada, assignor of one-half to Stephen Lemuel Tingley, Ottawa, Canada. Filed April 1, 1907. The material under treatment comes in contact with serially-arranged electrodes, and means are provided for varying the chemical conditions in each electrode chamber.

900,208. ELECTRIC LAUNDRY IRON. Earl H. Richardson, Ontario, Cal., assignor to Pacific Electric Heating Company, Ontario, Cal. Filed December 2, 1907. There is a thermic fuse in circuit with the heating unit.

900,214. VENT-VALVE FOR AUTOMATIC TRAIN STOPS. Hiram G. Sedgwick, Mill Valley, Cal. Filed June 29, 1907. Means are provided for giving the valve a differential movement.



900,192.—Electric Furnace.

900,215. AUTOMATIC TRAIN STOP. Hiram G. Sedgwick, Mill Valley, Cal. Filed September 4, 1907. Means are provided for manually operating the circuit-breaker and for automatically restoring the circuit-breaker to a normally closed position. A registering device is operated every time the circuit-breaker is released.

900,216. AUTOMATIC TRAIN STOP. Hiram G. Sedgwick, Mill Valley, Cal. Filed October 28, 1907. An eccentrically geared mechanism imparts to the valve a quick and slow movement.

900,217. AUTOMATIC TRAIN STOP. Hiram G. Sedgwick, Mill Valley, Cal. Filed January 4, 1908. A supplemental vent is operated after the main vent is closed. Means are provided for manually closing this supplemental vent.

900,238. TELEGRAPH KEY. James Z. Tucker and Lawrence V. Tucker, St. Louis, Mo. Filed December 16, 1907. The throwing-in switch is adjacent to the key-button.

900,266. HOOD AND REFLECTOR. George Cutter, South Bend, Ind. Filed October 30, 1907. A weatherproof cluster reflector.

900,273. ELECTRIC RAILWAY SIGNAL SYSTEM. Thomas M. Freeble, Latrobe, Pa. Filed June 7, 1907. A lever arm and contacts are actuated by the passage of the trolley wheel.

900,278. ELECTROLYTIC ALTERNATING-CURRENT RECTIFIER. Arthur S. Hickley, Manasquan, N. J. Filed November 12, 1907. The electrolyte contains a substance for preventing oxides and precipitates forming and collecting in the cell.

900,279. ELECTROLYTIC ALTERNATING-CURRENT RECTIFIER. Arthur S. Hickley, Manasquan, N. J. Filed January 16, 1908. One electrode extends across the cell near the bottom and through one wall.

900,289. SYSTEM OF CONTROL FOR ELECTRIC MOTORS. Benjamin G. Lamme, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. Filed December 4, 1905. An auxiliary field magnet winding remains open-circuited when the motor is operated by alternating currents, but is closed-circuited on itself when the motor is operated by direct currents.

900,292. ELECTRIC CURLING-IRON HEATER. Wynn Meredith, San Francisco, Cal., assignor to Pacific Electric Heating Company, Ontario, Cal. Filed September 25, 1907. The heating element is adapted to receive a curling iron.

900,295. ELECTRIC HEATING DEVICE. William C. Mortensen, Salt Lake City, Utah, assignor of one-half to Joseph R. Harris, Woodruff, Ida. Filed April 6, 1908. Resistance lamps are contained between an outer and inner cylinder.

900,304. ELECTROMAGNET FOR TELEGRAPHONES. Peder O. Pederson and Valdemar Poulsen, Copenhagen, Denmark, assignors to American Telegraphone Company. Filed April 9, 1902. Means are provided for directing an effective number of lines of force outside the coil.

900,320. CIRCUIT-INTERRUPTER. Cullen B. Snell, Bradford, Mass. Filed February 18, 1907. The circuit-operating device is yielding supported by a plurality of contact springs.

900,340. APPARATUS FOR ELECTROPLATING. John A. Yunck, South Orange, N. J. Filed November 8, 1906. The cathode, or negative pole, is adapted to hold an incandescent electric lamp. The anode has its operative face shaped to conform to the adjacent surface of the lamp bulb.

900,344. MAGNETIC OPERATING MEANS FOR CAMERA SHUTTERS. Arnold Bartels, Los Angeles, Cal., assignor of one-half to Rosa Hug, Los Angeles, Cal. Filed June 10, 1907. The shutter-operating arm is actuated by means of an electromagnet.

900,359. CHANGING BATTERIES IN ELECTRICALLY PROPELLED VEHICLES. Albert J. Doty, Mount Vernon, N. Y., assignor of one-half to Charles Berg, Philadelphia, Pa. Filed February 3, 1908. Battery trucks are disposed on opposite sides of the vehicle, in position to deliver a battery to one side of the battery receptacle, and receive a battery from the other side.

900,370. BLOCK-SIGNALING SYSTEM. John S. Holliday, Wilkinsburg, Pa., assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed February 21, 1908. The track rails are electrically continuous for all currents and equipped with synchroscopic relays having a movable element connected across the track rails.

900,372. ANTISEPTIC MOUTHPIECE FOR TELEPHONES, SPEAKING TUBES, ETC. Milton S. Hufschmidt, San Francisco, Cal. Filed April 7, 1906. A porous disc extends transversely across the interior of the mouthpiece.

900,382. MOISTURE-PROOF CASE FOR INSULATED WIRES. Adrian L. Joynes, Paducah, Ky., assignor of one-third to Charles L. Meyers, St. Louis, Mo. Filed June 4, 1906. A terminal head adapted to be hermetically sealed by screw-threaded rims and sectional washers.

900,386. TELEPHONE TRANSMITTER. Adolph G. Kaufman and Leopold J. Lippmann, New York, N. Y., assignors to American Callaphone Company, New York, N. Y. Filed January 19, 1907. The diaphragm is actuated by a plurality of mouth-pieces.

900,387. TELEPHONE RECEIVER. Adolph G. Kaufman and Leopold J. Lippman, New York, N. Y., assignors to American Callaphone Company, New York, N. Y. Filed February 7, 1907. A loud-speaking receiver.

900,392. SOUND RECORDING AND REPRODUCING INSTRUMENT. Georg Kirkegaard, New York, N. Y., assignor to Stilson Hutchins, Washington, D. C. Filed November 18, 1899. Means are provided for successively magnetizing a number of bodies in accordance with sound waves and a diaphragm subjected to the successive action of said bodies.

900,404. TELEPHONE DESK SET. Rap H. Manson, Elyria, Ohio, assignor to Dean Electric Company, Elyria, Ohio. Filed August 23, 1907. Means are provided within the upright for securing the upper hinge member to the base.

900,416. ELECTRIC GLOW LAMP. Walther Nernst, Göttingen, Germany, assignor, by mesne assignments, to Nernst Lamp Company, Pittsburg, Pa. Filed March 29, 1898. The element comprises a mixture of zirconium oxide and another refractory metal oxide.

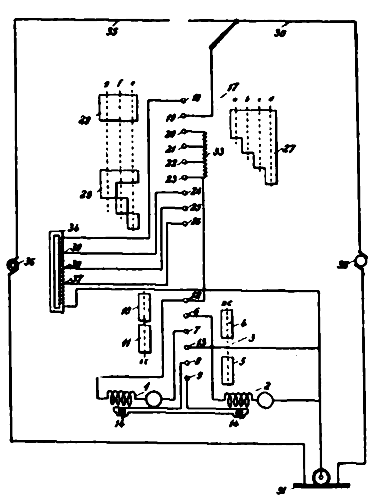
900,420. VARIABLE-SPEED MOTOR. Alvin A. Pifer and Charles E. F. Ahlm, Cleveland, Ohio, assignors, by mesne assignments, to F. B. Wagner, Cleveland, Ohio. Filed February 14, 1906. The regulator is equipped with two pole-shoe sections adapted to be moved from and toward each other.

900,426. SHADE AND SOCKET FOR INCANDESCENT LAMPS. Benjamin P. Rucker, Wilkinsburg, Pa. Filed June 21, 1906. The lamp socket is located entirely within, and sheathed by, the cap or dome of the shade.

900,429. ELECTROSONATOR. Ryusai Sakamoto, Tokyo, Japan. Filed April 11, 1907. A regulating socket is moved laterally to vary its point of contact on a spring plate.

900,447. ANTISEPTIC ATTACHMENT FOR TELEPHONES. Frank C. Tabler, St. Louis. Mo., assignor of fifty-one one-hundredths to Gus V. R. Mechin, St. Louis, Mo. Filed January 24, 1908. Fibrous material is arranged in front of, and parallel to, the diaphragm of the telephone. Means are provided for supplying said material with an antiseptic medium.

900,456. BLOCK-SIGNAL SYSTEM FOR RAILWAYS. James T. West, Rockingham, N. C. Filed March 25, 1908. A signaling circuit is adapted to be carried by a train or vehicle having a suitable signaling device therein responsive to current impulses through the track circuit.



900,289.—System of Control for Electric Motors.

900,458. TELEPHONE TESTING SYSTEM FOR PARTY LINES. Charles S. Winston, Chicago, Ill., assignor to Kellogg Switchboard and Supply Company, Chicago, Ill. Filed May 31, 1905. Means are provided whereby a special tone is produced in the operator's receiver when the busy circuit is closed.

900,476. COVER FOR ELECTRIC BATTERIES. Horatio J. Brewer, New York, N. Y. Filed May 29, 1908. The cover is arranged to carry the carbon and zinc elements and effect a moisture-tight cell.

900,478. ALTERNATING-CURRENT MOTOR. James H. Bryson, St. Louis, Mo., assignor to Wagner Electric Manufacturing Company, St. Louis, Mo. Filed October 7, 1907. Means are provided for shifting the pole phases.

900,486. ELECTRIC FURNACE. Erik Cornelius, Trolhättan, Sweden. Filed July 9, 1908. One electrode is fixed and the other is adapted to travel along the top of the chamber.

900,489. TELEPHONE EXCHANGE SYSTEM. William W. Dean, Elyria, Ohio, assignor to the Dean Electric Company, Elyria, Ohio. Filed October 18, 1906. An automatic ringing device comprising a ringing relay with line and generator connections.

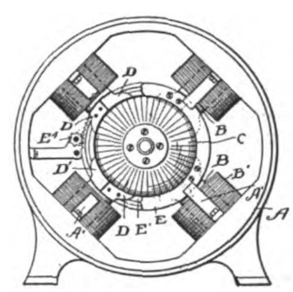
900,493. APPLIANCE FOR THE CURE OF RHEUMATISM AND OTHER DISEASES. Daniel R. Dewey, Hamilton, Ontario, Canada. Filed December 26, 1907. A blue-glass receptacle encloses an electric light filament, and is covered with a perforated non-combustible substance.

900,502. ELECTRODE FOR ELECTROLYTIC PURPOSES. Paul Ferchland, Berlin, and Joseph Nussbaum, Charlottenburg, Germany. Filed November 5, 1906. The conductors are dipped into a solution of lead sale, and current passed through said conductors and solution until a deposit of considerable thickness is formed.

900,529. PROGRAMME ATTACHMENT FOR CLOCKS. Julius W. Hansen, Princeton, Ind. Filed February 28, 1908. Means are provided to close an electrical circuit at any desired time.

900,542. ELECTRIC GENERATOR. Gottlob Honold, Stuttgart, Germany. Original application filed April 30, 1902. A high-tension spark generator.

900,553. TELEGRAPHIC RELAY. Isidor Kitsee, Philadelphia, Pa. Filed February 14, 1908. Means are provided to lower the resistance of a series of independent selenium cells through incoming impulses, and to move after each impulse the selenium cell formerly in the local circuit out of said circuit, and to move a selenium cell formerly out of said circuit in operative connection with said circuit.



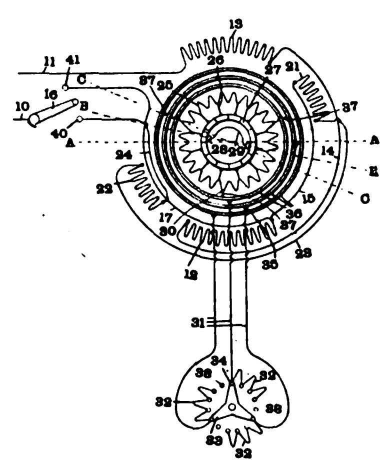
900,420.—Variable-Speed Motor.

900,555. CONTROLLING SYSTEM FOR ELECTRIC MOTORS. Benjamin G. Lamme, Pittsburg, Pa., assignor to Westinghouse Electric and Manufacturing Company. Original application filed December 4, 1905. Means are provided for arranging the circuit relations of the motors in accordance with the character of the energy supplied thereto.

900,571. SECONDARY BATTERY. William Morrison, Chicago, Ill. Filed June 8, 1903. A reversible electric galvanic battery.

900,597. PROCESS FOR PRODUCING AN ELECTROLYTIC DEPOSIT OF METALLIC CHROMIUM. Franz Salzer, Dresden, Germany. Filed January 16, 1908. Metallic chromium is produced by employing a bath containing a mixture of chromic acid and chrome oxide.

900,602. MASSAGE VIBRATOR. William G. Shelton, Chicago, Ill. Filed September 3, 1907. A motor operates the vibrating head.



900,478.—Alternating-Current Motor.

900,613. AUTOMATIC CIRCUIT-CLOSER FOR ELECTRIC-LAMP HOLDERS. William D. Tickner and Lucius C. Tickner, Blanchardville, Wis., assignors of one-half to Charles M. Crowell, Blanchardville, Wis. Filed February 3, 1908. The movement of the plunger closes the circuit and shifts the position of the lamp.

900,641. ELECTRIC FIRE ALARM. Harry Anderson, Haddonfield, N. J. Filed February 14, 1908. Fusible means are provided between a movable lug and a stationary lug.

900,658. REMOTE-CONTROL ELECTRIC SWITCH. Jay S. Bristol, Gillespie, Ill. Filed April 6, 1907. Means are provided for determining the direction of circuit closers.

900,676. TELEPHONE EXCHANGE SYSTEM. Ray H. Manson, Elyria, Ohio, assignor to the Dean Electric Company, Elyria, Ohio. Original application filed February 1, 1907. A plurality of ringing generators is adapted to supply current of different frequencies.

CONTENTS

MUNICIPAL STREET LIGHTING CONTRACTS.

Among the problems of central station work which involve close appreciation of both technical and commercial elements for the largest success and most lasting satisfaction between a company and its customers the modern street lighting contract takes a prominent place. The taxpayer realizes that the cost of street lighting is a direct charge, and while he may be a power consumer in his private business, it is easy for him to look upon street lighting costs as sheer outgo, in comparison with the definite results which he obtains on his own premises for a given expenditure devoted to lighting or motor service. The approach of a renewal time in a street lighting contract is only too often the signal for unfair attempts on the part of the politicians to scale down the charges for service, and as everybody is interested in the quality and amount of illumination provided in the thoroughfares of a city buying central station current, it is easy to stir up public opinion on the rate question. A most important part of the central station manager's work is therefore the study of street lighting conditions in other communities, in order to meet unfair attempts to secure reductions by definite explanations of differences in local conditions that justify differences in rates or service, and to provide on the other hand the best service that is available in the art.

The form of street lighting contract desirable will naturally vary widely in different cities and towns, but in general the more definite the contract as to the service to be rendered, the price to be charged, the privileges of the two parties, and the inclusion of possible new conditions, the less opportunity there will be for future disagreement.

A well-drawn contract will, it would appear, state definitely the extent of service and its duration, with the course to be followed in case a named maximum number of lights are desired to be exceeded by the city. It is desirable from the city's standpoint to state in the contract that the price named covers the service, the company being required to bear the cost of generating the current, and as a rule paying for the supplying and maintenance of all lamps, poles, wires and attachments. The rating of the lights is obviously one of the most vital points to define, and all hazy specifications should be avoided on this point. Thus, in a recent contract the lighting unit is specified as of "not less than two thousand nominal candle-power, and as long as the present type of alternating-current lamps are used the current supplied shall be not less than seven and one-half amperes intensity, and the apparent watts shall be not less than 540 at the lamp." This particular specification wisely brings the lamp size down to accurately and easily measurable quantities, and still provides for future improvement in the art. Too close a specification on a single point tends to prevent the municipality from enjoying the advantages of progress in equipment manufacture, as in the case of an eastern city which required the company to supply incandescent lamps of a certain wattage each, regardless of their candle-power.

The privilege of installing testing instruments, either of the indicating or recording type, is sometimes allowed the municipality, and it is not considered unfair to the company to require recording ammeter charts showing the hours of service and the outages to be submitted with each bill. Either party may rightfully demand the recalibration of the recording meter at any time. The place where such meters may be installed, and the reduction allowed on outages should also be stated. In one recent contract of this character the bill is reduced two cents per hour per lamp for each ampere or fraction thereof that the current falls below 7.5 amperes, up to a total of four cents per lamp per hour. Right to use the public thoroughfares for construction of street lighting equipment and its maintenance may properly be incorporated in the contract, to save time and formality in regard to permits when work is to be done. No charge should be made by the municipality to the company for any pole or fixture work under the duties of the street lighting service.

Unless the terms of lighting and extinguishment are positively and definitely set forth in such a way that no possible misunderstanding can arise, the contract is faulty. If any lighting schedule or table is referred to it should either be included in the contract text or attached as an included supplement. Another wise provision is to specify the heights permissible for lamp suspension, the quality of fittings desired and the conditions under which tree trimming may take place. Continuous service is so essential to this class of work that generally a brief statement to the effect that the company shall maintain a patrol system and emergency force required to handle outages or defects at the earliest feasible moment on report from police officers or individuals is all that is needed. In some cases it is desirable for the company to furnish the city a map, showing the location of all poles, wires and lamps used in the arc service, filing a new and corrected map at the office of the city engineer whenever a change of any consequence is made. A fair appreciation of mutual conditions will do much to create good feeling and avoid disagreements. The right of the city to install and maintain fire-alarm and other municipal signaling wires on the lighting poles for street service is frequently considered fair by central stations. The day of the month upon which payments are due from the city may properly be included. If at any time the city desires new types of equipment for use in its street lighting service, the contract ought to provide the course to be followed in conference with the company, together with provision for appeal to an arbitrating authority in case of disagreement. The central station can request the inclusion of a provision for the extension of the contract for given period if it desires, without going to the trouble of rewriting the contract in detail.

ELECTRIC POWER IN SOUTHERN MILLS.

Cotton mills in the South are rapidly abandoning steam plants in favor of power from the hydroelectric companies. One of the hydroelectric systems in the Piedmont region of North and South Carolina, where the majority of the southern cotton mills are located, is now operating more than seventy of these mill plants, and most of the mills have been connected to its lines within the past two years.

As a rule, these cotton mills operate about 3,300 hours per year, when there is enough business, and electric power is usually sold to them at so much per kilowatt-hour, recorded by a meter, so that the only payment by a mill is for energy received.

Rates vary, but eight-tenth cent per kilowatt-hour, or about $26 per kilowatt for an operating year of 3,300 hours, is a common rate, while some mills do better than this. Lower rates are made to mills that own substations and receive their energy at the voltage of transmission than to mills that are supplied with current at motor voltages by the hydroelectric companies.

Formerly most of the motors in cotton mills were operated at about 550 volts, and substations were designed to distribute current at this voltage. As this practice tended too much to the multiplication of small substations, of less than 1,000 and even less than 500 kilowatts capacity each, with a high cost per kilowatt, the hydroelectric companies have offered some inducements in rates to mills taking current at about 2,000 volts, and many mills now operate motors at this voltage. Where a mill operates with individual motors of twenty-five-horse-power or less for its looms, it is often necessary to step down the 2,000-volt current to 550 volts.

Most, if not all, of the electric power supplied to cotton mills in the Piedmont region is three-phase at sixty cycles. The choice of sixty cycles by the hydroelectric companies appears to have been mainly influenced by the fact that mills using electric drive from local power plants, when the electric companies came into the field, were mostly equipped with sixty-cycle motors, that the power demands of the cotton mills were much greater than any railway loads in prospect, and that generators, transformers and motors are cheaper for sixty than for twenty-five cycles.

Cotton-mill loads are remarkably constant during the hours of each day when in operation, so that a large generating station driving dozens of these mills on a long transmission line shows a variation of less than ten per cent in load from 6 A. M. to 6 P. M., except at the noon hour. For this kind of load the highest points appear to be reached at about 9 A. M. and 3 P. M. The consumption of electric energy from day to day is also very uniform in cotton mills, the variation being usually less than ten per cent, except on Saturday when the hours of operation are less than on other week-days.

Southern cotton mills may be contrasted with those in the North as to the larger number of the former often found in one city or town, and as to their consequent small capacity. The average power required by the southern cotton mill is therefore small.

One of many illustrations on this line may be noted at Concord, N. C., a city of 7,910 people in 1900, where there are ten different cotton mills with a combined equipment of 149,310 spindles, 3,495 looms and electric motors and steam engines of 5,610 horse-power. The average equipment for each of these ten mills is thus 14,931 spindles, 349 looms, and driving apparatus of 561 horse-power. In five of these Concord mills the driving power is taken from the transmission lines of a hydroelectric company.

Records of operation here presented for two southern cotton mills show well the uniform character of their loads, and consequent high-load factors. One of these is a cotton-spinning mill operating sixty-six hours per week, and during one week of normal operation the total consumption of electric energy was 12,650 kilowatt-hours, giving an average load of 191.6 kilowatts. The meter indication of power in use at this mill was taken at about 2 P. M. on two days and was found to be 208 and 210 kilowatts respectively. During twelve months, frequent observations of the meter disclosed a maximum load of about 220 kilowatts at this mill. On this observed maximum the average of 191.6 kilowatts gives a load factor of eighty-seven per cent.

Another cotton mill is supplied with electric current at about 2,000 volts from transformers of 475 kilowatts total capacity, for motors of 445 aggregate horse-power, driving 14,000 spindles and 800 looms. This mill operates sixty-two hours per week, and driving one week of normal operation the energy consumed amounted to 19,050 kilowatt-hours, corresponding to an average load of 307 kilowatts per day. During a period of twelve months the maximum reading of the meter at this mill showed a load of 320 kilowatts, so that the load factor, on the basis of the average of 307 kilowatts noted above, was ninety-six per cent. Another normal week of operation at this last-named mill showed a consumption of 19,650 kilowatt-hours, corresponding to an average load during the hours of operation of 317 kilowatts and to a load factor of ninety-nine per cent. So high a load factor raises a doubt as to the accuracy of the reported maximum load of 320 kilowatts during the entire year, but in any event the load factor is very high. The load factor here considered is, of course, taken for the hours of operation only and not for the entire twenty-four hours of each day.

At the last-named mill the motor capacity of 445 horsepower is the equivalent of 333 kilowatts, and with an efficiency of ninety per cent the power demand with all motors at rated load would be 370 kilowatts. The average load of 317 kilowatts is thus about eighty-five per cent of the demand of all motors at normal load.

Several of the above features of its cotton-mill loads make the South an attractive field for the construction of hydroelectric plants. As the cotton factories are split up into rather small units that require only 500 to 600 horse-power each, on an average, the cost of steam power at each mill must be greater than it is in the larger plants at the North, and this tends to keep up the price of electric power. Besides this, few industries show better load factors than those indicated above.

MACHINERY DATA FOR PURCHASERS.

Whenever an intending purchaser of machinery asks a manufacturer for technical data regarding his product it is more important than is always appreciated to supply information of this character promptly. A well-conducted district office should usually be provided with all the important dimensions of standard apparatus, its capacity under clearly defined conditions of service and its approximate cost for preliminary figuring. Where special machinery must be designed and built or where standard equipment must be somewhat modified in order to effect a sale it is out of the question to expect the manufacturer to supply detailed figures at short notice, but certainly so far as regular products are concerned there is little excuse for delay.

There is no doubt that some prospective purchasers call for data with very little idea of awarding the contract to the company which supplies them, and sometimes even the buyer of apparatus will ask for the most minute details of the equipment-points which do not concern him in the slightest direct way in the matter of operation. In the sale of a new design of electric motor, for instance, a purchaser may call upon the manufacturer to give him a copy of the detailed design, showing the exact cross-sections of the magnetic circuits, the number of turns of wire on each coil, dimensions of commutator bars, bearing surface and many other facts. Whether the manufacturer gives out this sort of information willingly or not, most of it can be determined if the purchaser cares to take the trouble, so there is little reason to hold back such data from bona-fide purchasers. It may be well to request that the information be kept as confidential, and most buyers of machinery are willing to accede to a reasonable request of this sort, but after all, mere possession of the statistics of a machine design far from qualifies the holder to reproduce the actual apparatus. It is entirely proper, however, that the innermost details of a costly machine design should be difficult of access, protected though they may be by patent rights.

It is an actual fact that the failure to furnish such information as the capacity of apparatus, its over-all dimensions, weights, number and size of important parts, areas of working sections, etc., at an early stage of the negotiations with a prospective purchaser may result in serious delay to all parties concerned, and if these data are withheld after the apparatus is installed, considerable inconvenience may result. Particularly when sudden interruptions of service occur is it essential to know the principal technical data of a piece of machinery in order to expedite repairs and the replacement of extra parts that may often have to be ordered by wire. Among the loose ends which remain to be cleared up after a new installation begins service there is nothing of more importance to the purchaser than the possession of sufficient information to enable him to maintain as well as operate the apparatus. A narrow policy in supplying blue prints and other important data on the part of a manufacturer may easily prejudice the purchaser against him in future selections of equipment.

Street Railway Conventions.

Meetings of the American Street and Interurban Railway Association, the Accountants', Engineering, Claim Agents' and Transportation and Traffic Associations, Atlantic City, N. J., October 12-16.

THE annual meetings of the American Street and Interurban Railway Association and its affiliated organizations, the Accountants', Engineering, Claim Agents' and Transportation and Traffic Associations were held at Atlantic City, N. J., October 12 to 16. Sessions were held on the morning and afternoon of each day, and in addition to the exhibit of the Manufacturers' Association there were a number of entertainments which were greatly enjoyed.

On Monday the Atlantic City Business League held a carnival, with a military parade and industrial parade on Atlantic Avenue. In the evening there was a display of fireworks and a musical carnival near the city hall. Later in the evening an informal dance was given in the ballroom of the Marlborough-Blenheim Hotel.

On Tuesday evening the annual reception of the associations was held in the solarium of the Marlborough-Blenheim. The soloists were Miss Margaret Keyes and Oley Speaks.

On Wednesday afternoon the ladies of the associations were entertained at the Country Club of Atlantic City. On Wednesday evening the Manufacturers' amateur vaudeville and theatrical performance was given at the Savoy Theatre.

On Thursday afternoon the ladies of the convention were tendered an entertainment in the solarium of the Marlborough-Blenheim Hotel, Miss Amy Grant giving a series of musical readings. On Thursday evening there were theatre parties at the Apollo and Savoy Theatres.

On Friday evening there was an entertainment in the solarium of the Marlborough-Blenheim.

Headquarters were established for convention registration and other business on Young's million-dollar pier. The American association and Manufacturers' association established hotel headquarters at the Marlborough-Blenheim, the Accountants at the Chalfonte, the Engineering association at the Dennis, the Claim Agents at the Traymore, and the Transportation and Traffic association at the Traymore.

The morning of Monday was given over to the registration of the delegates and guests and to preparation for the technical sessions.

The American Street and Interurban Railway Association.

THE first meeting of the American Street and Interurban Railway Association was called to order at 3 P. M. on Tuesday by Vice-President Shaw, acting as chairman in the absence of President Calvin G. Goodrich. Mr. Shaw read a letter from the president expressing his regret at being unable to be in attendance at the convention.

The report of the executive committee was read and approved.

The secretary's annual report was presented and accepted.

The annual address of President Goodrich was read by Mr. Shaw. It contained several suggestions concerning the future policy of the association. The suggestion that the association appoint separate times and places for holding the annual conventions of certain of the affilated associations was discussed, and it was considered inadvisable on account of the importance of the subject to take immediate action. A resolution was introduced by W. G. Ross and adopted as follows: "That a discussion be held at Thursday's session with the idea of appointing a committee to study the question, this committee to make a report, which is to be distributed among the members."

The Committee on Badges reported that a badge for associate members had been adopted.

The report of the Committee on Membership was presented, followed by the report of the Committee on Subjects.

The final business of the session was the hearing of the report of the Committee on State and Federal Regulations.

The Wednesday session was called to order by Vice-President Shaw at 2.15 P. M.

The report of the Committee on Education was presented by Professor A. S. Richey, in the absence of the chairman, H. H. Norris. This report described the apprenticeship courses adopted by the New York Central Railroad Company, the Master Mechanics' Association, the Trustees' Gas Educational Fund, and the Edison companies. The results of the apprenticeship work have been very satisfactory, and the report concludes that the example being made by the railway and lighting industries in the training of employés indicates the importance and value of the work. Some form of cadet or apprentice plan seems necessary to the best development of employés, but the plan must be adapted to local conditions.

This report was discussed by Professor D. C. Jackson, who said that but few electric railway corporations had shops and construction organizations of such magnitude as to make it desirable to establish an apprentice course. On the other hand, there are many companies employing large numbers of men who are without advanced technical training. Such companies would find it well worth while to establish courses of training, and it seemed that the extension of the cadet system among the various electric railway companies would lead to an ultimate enlargement of the body of competent and able engineering and executive officers which the companies would have to draw from.

The report was also discussed by C. H. Hile, of the Boston Elevated Railway Company; Howard F. Grant, who described the system employed by Stone & Webster, and L. H. Storrs.

W. Caryl Ely delivered an address on the subject "How Can the American Street and Interurban Railway Association and Its Affiliated Associations Be Made of the Greatest Value to the Member Companies"?

Mr. Ely believes that the different classes of work should be subdivided and committed to the care of various committees, so that ample time could in that way be had for proper investigation.

A communication was presented from the *Electric Railway Journal*, offering to compile and publish, free of any cost to the organization, an electric railway dictionary, and requesting the association to name an editing committee, this committee to be an advisory committee on the publication of the dictionary. This proposition was approved and the following committee appointed by the chairman: H. H. Adams, New York; Paul Winsor, Boston; Richard McCulloch, St. Louis.

The constitution and by-laws of the American Street and Interurban Transportation and Traffic Association were approved, and a communication from the J. G. Brill Company was read, offering a prize to students in the technical schools of the country for the best thesis on city and interurban cars. It was decided to authorize the incoming president to appoint a judge to act in conjunction with S. M. Curwen and H. W. Blake.

The Thursday session of the American association was called to order by Vice-President Shaw at 2.50 o'clock.

The report of the Committee on Insurance was presented and accepted.

E. G. Connette, chairman of the Committee on Welfare of Employés, presented the report of this committee.

Following the discussion on this report, the report of the Committee on Nominations was presented and accepted as follows: President, James F. Shaw, Boston, Mass.; first vice-president, Arthur W. Brady, Anderson, Ind.; second vice-president, Thomas N. McCarter, Newark, N. J.; third vice-president, Gen. O. H. Harries, Washington, D. C.; fourth vice-president, Charles N. Black, San Francisco, Cal.

The Committee on Resolutions presented a report thanking the Manufacturers' association for bringing together the elaborate collection of railway appliances on exhibition. The report also presented resolutions thanking the mayor of Atlantic City, the Atlantic City Business Men's League, the Atlantic City Hotel Men's Association, the technical and local press, the officers and committees of the association, the committee which had carried out the conferences with the Interstate Commerce Commission on depreciation, and President Goodrich.

Resolutions of regret upon the death of C. Densmore Wyman and John A. Brill were also presented.

The convention of the American association was then adjourned.

The Accountants' Association.

THE twelfth annual meeting of the American Street and Interurban Railway Accountants' Association was called to order at the Chalfonte Hotel at 10 A. M. Wednesday by R. N. Wallis, acting president.

The records of the last meeting were read and approved, and Mr. Wallace delivered the annual address of the president.

Acting Secretary H. E. Weeks read the report of the executive committee, recommending an addition to Section 1 of the by-laws, as follows: "All past-presidents of the American Street and Interurban Railway Accountants' Association and its predecessor, the Street Railway Accountants' Association of America, shall be honorary members of the executive committee without the right to vote."

The appointment of a committee upon inter-line accounts was also recommended.

W. H. Forse, Jr., explained that the Central Electric Accounting Conference, an informal association composed of the accountants of various electric railways in the Central States, had been organized in order that the accountants might get together and discuss matters of mutual interest at more frequent intervals than the meetings of the national association afforded. At a meeting in Indianapolis recently the subject was brought up, and it was suggested that the American association be asked to act in the matter, so that it would be broader in its scope, and not only affect the railways in the Central States, but all the electric railways in the country that are interested in inter-line accounting. It was decided that the chair appoint a committee of five to act on this matter.

The report of the treasurer showed that the expenditures during the fiscal year were $1,794.66. Standard classifications sold during the year amounted to $119.50.

F. W. Sweney, special examiner Interstate Commerce Commission, addressed the meeting, and stated that the commission had issued three classifications which will become effective on January 1. He was satisfied that if there were any points in which the classifications were not clear they could be developed, and that the commission would be glad at any time to receive suggestions with regard to any points which might be disputed.

A. R. Patterson read a paper entitled "Organization of the Accounting Department of an Electric Railway and Light Company."

There was considerable discussion on this subject, and the meeting adjourned after the appointment of nominating and resolution committees.

The Thursday session of the Accountants' association was called to order at 10.20 A. M. Fred G. Simmons, president of the Engineering association, addressed the meeting, and his recommendation for the appointment of a joint committee was referred to the incoming executive committee.

Ellis G. Carpenter, representing the Claim Agents' Association, addressed the convention, followed by William H. Forse, Jr., who presented a paper entitled "Inter-Line Accounting of Interurban Railways."

Mr. Forse was followed by A. F. Weber, statistician for the Public Service Commission for the First District, New York, who made a brief address.

The Friday session of the Accountants was called to order at 10.20 A. M., and the paper by A. B. Bierck, entitled "Effect of Electrification on Accounting Methods of Steam Railways," was read by Acting Secretary Weeks.

Frank R. Henry, who resigned as president of the association during the year because of his resignation from the United Railways Company, of St. Louis, to engage in other business, was elected an honorary member of the association.

The incoming executive committee was directed to take up with the Transportation and Traffic association the desirability of the appointment of a joint committee to consider questions of interest to that organization and the Accountants' association. It was also proposed that similar committees be created with the Claim Agents' association and with the Engineering association.

It was voted to direct the incoming president to request the president of each of the various state electric railway associations to appoint one member to keep the member companies in such associations in touch with the work of the Committee on Standard Classification of Construction and Equipment Accounts and form of report of the Accountants' association.

Acting President Wallis appointed the following Committee on Inter-Line Accounts: W. H. Forse, Jr., Indiana Union Traction Company, chairman; Irwin Fullerton, Detroit United Railway Company; C. L. Wight, Interurban Railway Company, Des Moines, Iowa.

R. N. Wallis, treasurer of the Fitchburg & Leominster Street Railway, Fitchburg, Mass., was elected president for the ensuing year. The office of secretary and treasurer is purely honorary. H. E. Weeks, secretary and treasurer of the Tri-City Railway Company, Davenport, Iowa, was elected to fill this position.

The convention was then adjourned.

The Engineering Association.

THE American Street and Interurban Railway Engineering Association held sessions on Tuesday afternoon, Wednesday morning and Wednesday afternoon, and Friday morning and afternoon. The sessions were devoted entirely to the reports of committees, taking up the special work which comes under the jurisdiction of the engineering department, and on Friday afternoon the following officers were elected: President, Paul Winsor, Boston, Mass.; first vice-president, F. H. Lincoln, Philadelphia, Pa.; second vice-president, W. H. Evans, Buffalo, N. Y.; third vice-president, W. J. Harvie, Utica, N. Y.; secretary and treasurer, John W. Corning, Boston. Executive committee: William Roberts, Akron Ohio; E. O. Ackerman, Columbus, Ohio; L. L. Smith, Highwood, Ill.; Martin Schreiber, Newark, N. J.

TUESDAY AFTERNOON SESSION.

The first session of the Engineering association was called to order by President Fred G. Simmons at 2.45 P. M. on Tuesday. President Simmons then delivered his annual address. He stated that the idea of carrying on the work of the association by means of standing committees had been put into effect to such an extent that all the work presented by the association this year, excepting only the question box, was carried on by the standing committees. At the present time there were committees covering practically the entire field, but it will undoubtedly be found desirable to add, to change and to supplement these committees as further progress is made. It was advisable that the standing committees endeavor to make definite recommendations as their work progressed.

He called attention to the lack of co-operation on the part of some member companies with regard to filing complete answers to the data sheets distributed by the standing committees.

The report of the executive committee was presented, which was adopted.

The report of the secretary and treasurer was presented. This showed that the expenditures during the fiscal year ending October 16 were $1,983.86. There was a balance on hand of $4.37. The association received from the American association $1,950, and from miscellaneous sources $38.23.

The report of the Committee on Maintenance and Inspection of Electrical Equipment was presented. This report was prepared by L. L. Smith, chairman; E. T. Munger, C. C. Long, L. W. Jacques and F. P. Maize. It was abstracted briefly by Mr. Munger.

This report was developed along the same general lines as were followed last year. Specifications for important items of supplies were added and the rules governing the maintenance and inspection amplified. The general subject of the report was divided under various subheads and considered separately as follows: Carbon brushes for railway motors; Insulating materials for railway repair shop use; Recommendations of committee of last year—extent to which they have been approved and followed; Gear and pinion specifications; Lubrication; Gear and pinion lubrication; Rules for lubrication for the guidance of car-house employés; Armature and axle liners; Trolley wheels; Air-compressor maintenance; Air-compressor inspection; Time versus mileage basis car-house organization; Practical rules for the inspection of electrical equipment, for the guidance of car-house employés; Home-made tools and devices.

The committee reports a greatly increased interest in the work by the member companies, the data sheets having been filled out in a complete and painstaking manner. The thanks of the committee were extended to E. H. Anderson, of the General Electric Company, and J. L. Davis, of the Westinghouse Electric and Manufacturing Company, who rendered valuable assistance in the preparation of this year's report, and also that of last year.

The discussion was opened by E. W. Olds, who analyzed the various subdivisions and called attention to the number of recommendations which had really been put into practice by the member companies.

The committee recommended as one of the tests for carbon brushes a vibrating test using a rotating disc with a drop of one-eighth inch. One could hardly tell without trying it whether this test would be too severe. In his judgment this would seem to be the case. He was happy to say that there had been a considerable advance in the production of insulating material within recent years.

Concerning the gear and pinion specifications, it would seem that if the pinion steel was of the proper tensible strength, that the test would not show very much reduction of area. A dense and tough material must be secured. At the same time, the steel must have a high elastic limit. To-day there are very few companies using grease for lubrication, and even with old motors, oil is being very extensively employed.

Paul Winsor stated that his company had used about fifty impregnated coils with a good deal of success. With regard to babbitting, the company had held out against using patented babbitting, and had found its greatest success with the use of an expensive babbitting which ran high in tin. He had used a small trolley wheel, as light as could be got, but it had not been possible yet to convince his company that it could make any great saving by changing its procedure. He thought that the foremen's meetings were very important and helped materially in cutting down delays and improving the service. To-day the delays are one-half of what they were a year ago, and this improvement has been followed month by month throughout the year.

Mr. Adams endorsed Mr. Winsor's remarks, and said that he tried to go a little further, and in addition to decreasing troubles with the foremen, presented brief talks on interesting subjects. Representatives of the various companies had attended these meetings and talked to the men. Regarding the use of trolley wheels, he had found that the average life of a five-inch wheel was from 20,000 to 25,000 miles, as against 3,000 to 10,000 miles for four-inch wheels.

Mr. Doyle stated that in New York city service during the last year the company has secured about 3,000,000,000 miles of work with a certain type of carbon. This carbon had reduced the troubles on the Manhattan Elevated Railway eighty-five per cent, and had reduced the troubles in the subway about ninety-six per cent. The cost runs to about 17.3 cents per 1,000 car-miles, as compared with a former cost of forty-four cents.

E. Gindre, of Le Carbone Company, addressed the meeting on the matter of carbon brushes, and stated that there should be as many specifications for controlling carbon brushes as there are different grades taken as standards. He discussed the various tests. The vibrator tests he did not think corresponded closely enough to the conditions of practice. The shocks and vibrations to which traction brushes are normally subjected in actual service can not be compared with the exaggerated trial connected with the vibration test. The resistance test he had always found of value, as it answers more closely to actual practice. The abrasion test he considered would be a rational method when running the different brushes on soft material. The decrease in weight would be proportional to the abrasive coefficient. With regard to the subject of single and double widths of brushes, he thought the advantage of single-width brushes lay in a better distribution of the current, as they fitted the commutators more easily on account of their smaller section.

Mr. Brady, of the National Carbon Company, said the report was a step in the right direction. He thought, however, that most of the tests would be found impossible for most mechanics or men in the barns to make. Most of the tests were laboratory tests, which it was hard for those skilled in such work to make accurately. Unless extreme care were taken it was hard to bring the brush down to a true surface. The slip-ring test was a good test, but to his mind was more a matter of contact resistance than anything else—that is, a brush with a high-contact resistance will glow more quickly than a brush with a low-contact resistance. A brush with a high-contact resistance is a good brush to have in some cases, while one with a low-contact resistance is good in other cases. The manufacturing companies were glad to go into the matter of brush tests with anybody and make brushes for any specifications. It did not necessarily follow that if a brush would give 100,000 revolutions on a vibrator, and 300 amperes under test on a slip ring, that it would work satisfactorily on all motors.

Mr. Doyle suggested that the carbons be classified on the car-mileage basis. If their performance could be measured in this way it might prove a reasonable mark for the manufacturer to work to.

Taking up the matter of gears and pinions, Mr. Doyle said that his company had found that a special treatment of carbon steel increases its value as much as 100 per cent. It occurred to him that some suggestions might be made by the Standardization Committee with a view to designing some form of test which would indicate the wearing characteristics of different compositions of material which had been subjected to different courses of treatment.

Mr. Winsor said that the vibration test

would help a great deal. It would not fix a standard of how many vibrations a certain brush would make, but it would show that under certain conditions, if a certain character of carbon would make 20,000 vibrations or revolutions, that it would be able to live up to certain conditions.

E. E. F. Creighton presented a paper entitled "Lightning Protection for Electric Railways."

This described the new types of aluminum arresters which have been developed by the General Electric Company for street-railway lightning protection.

Mr. Anderson took up the discussion of the gear and pinion specifications given by the committee. He said that the values given in the report are within the range of carbon steels, applying particularly to the service where they would be required. It will not be wise to run tensile strength and elastic limit tests too high, because this makes the tools too brittle and they will not stand the shocks.

The discussion of Mr. Creighton's paper was then taken up, and in reply to the question whether there was any well-defined method of applying lightning arresters with reference to the number installed per mile, Mr. Creighton stated that a great deal depends upon the internal resistance of the arresters. The idea of installing five or six lightning arresters to the mile was probably due to the fact that the arresters in themselves had a considerable internal resistance. If a cloud discharges directly over a line, the more arresters installed per mile the greater freedom will there be from trouble from such discharges. The line arrester would have little effect in taking care of a discharge just over a car, and dependence would have to be placed largely upon an arrester on the car. The line arrester can take care only of the discharge in its near vicinity, and it helps out in the general protection by reducing the quantity of discharge that the arrester on the car has to take care of. It is rather an undecided question if there should be more than two arresters per mile. Mr. Creighton thought that if there were a good discharge path, two arresters per mile would be sufficient to relieve the ordinary strain.

The further consideration of the subject of lightning protection on cars, on motion, was referred to the Committee on Maintenance.

The report of the Committee on Maintenance and Inspection of Electrical Equipment was accepted, and the report as a whole referred to the incoming committee, which would have charge of these matters.

The meeting was then adjourned until Wednesday morning.

WEDNESDAY MORNING SESSION.

The Wednesday morning session of the Engineering association was called to order at 9.30 o'clock.

The report of the Committee on Standardization was presented by H. H. Adams.

This report stated that the standards adopted by the association as a result of the report in 1907 are being seriously considered by the various electric railway companies and rapidly adopted by others throughout the country. This applies particularly to axles, journal bearings, journal boxes, brake shoes, brake-shoe heads and keys, and standard section of flange and tread of wheels. The present report recommends that the standard height of couplers for interurban cars from the top of rail to the centre of the coupler should be thirty-one inches. This is the standard adopted for all steam railroad passenger cars. The committee recommends that the standard height of couplers for city cars from the top of rail to the centre of the coupler be twenty inches.

With regard to the type of coupler to be recommended as standard for city cars, the committee suggests that the subject be continued for consideration for at least another year, or until a coupler has been developed of sufficient merit to meet with general approval and suitable for adoption as a standard. In selecting a proper type or pattern of coupler for interurban cars, the committee has been handicapped from the fact that no form of automatic coupler or attachment has been developed in practical service by which interurban cars can be coupled together and can also be directly coupled to standard steam railroad cars. The committee recommends the adoption as standard for interurban railways of a coupler of a vertical plane type which will have the same contour lines of knuckle and guard arm as will automatically couple with standard steam railroad couplers. It is also recommended that the distance from the centre of the pocket pin to the pulling face of the coupler be fifty-four inches. This length will apply equally as well for cars in city service. Where a bumper arrangement will permit, the committee recommends that on city cars a pocket casting should be placed on the top of the bumper, the centre of the pocket to be thirty-five inches above the top of the rail, and the casting to be of ample strength and properly braced, so that, by means of a suitable bar, city cars can be coupled on the level with the automatic couplers of interurban cars. It would appear that for the present, at least, it would be advisable to maintain a link slot and coupling pin hole in the knuckle of the automatic couplers.

For standard height of platforms for interurban cars the committee recommends that from the top of rail to the top of platform floor the height be fifty-one inches, and that the height for city cars from the top of rail to the top of platform be thirty-one inches.

So much variance in practice is found in the different cities concerning the height of car steps that the committee merely suggests the following as recommended practice for interurban cars: Height from top of rail to top of tread of first step, seventeen inches; to top of tread of second step, twenty-nine inches; to top of tread of third step, forty inches; to top of platform floor, fifty-one inches. Similar recommendations are made for the heights of step on city cars as follows: To top of first step, seventeen inches; to top of second step, thirty-one inches; height of riser from top of vestibule floor to floor of city car, ten inches.

The committee recommends that the bumper arrangement on interurban cars be made as solid and substantial as the design of the equipment will permit, and if possible, some suitable arrangement provided which will prevent the bumpers of interurban cars from passing over the bumpers of the lower city cars.

The committee also recommends that where possible the top of bumper on city cars be reinforced with a bumper casting of suitable design which will engage the bumper of the interurban cars as well as provide a wider surface, thus preventing the bumpers from passing over and the cars from telescoping in case of collision between city and interurban cars.

The committee recommends that the standard height for bumpers on interurban cars from the top of rail to the top of bumper shall be fifty-one inches, and the height from the top of rail to bottom of bumper, forty-three inches. The standard height from the top of rail to the top of bumper on city cars shall be thirty-one inches, and the width of bumper for city cars shall be six inches.

In opening the discussion Mr. Adams said he believed that the question of the height of bumpers is one of the most important considerations presented in the report.

Mr. Doyle stated that in his lay-up yards an eight-car train, running at a speed of thirty-five miles an hour, collided with a string of empty cars. One of the cars that was laid up was equipped with a bumper plate made of a steel casting with a corrugated face. This casting prevented the front car of the moving train from telescoping the rear car of the stationary train, but the cars following the leading car climbed over each other and destroyed the ends. The corrugated bumper plate engaged the other car and prevented it climbing up at that point. The condition of the cars at the other points in the two trains was a valuable demonstration of the efficiency of the corrugated buffer plate.

Mr. Olds stated that the ordinary steam coupler was not sufficient to take care of the vertical movement which obtained where the roads changed their grade. As far as the height of platform was concerned, he thought that the committee's recommendation of thirty-five inches, which is steam railroad practice, is what should be adopted because of the many roads handling steam cars over their tracks.

In reply to a question Mr. Doyle explained that the corrugated buffer which he described was placed in the end of the sills, and as the cars come together the line of sills is maintained and the force of collision is dissipated by throwing the cars off sideways. Unless the casting is placed right on the ends of the sills the great force of a high-speed collision would break down an ordinary platform. The construction of the car should permit the interlocking of the sills by their ends; then it is impossible for the car to telescope. If, in the ordinary city car which has a platform tied up to the main sills, the interlocking device is provided, the device is valuable only at such low speeds as the strength of the platform will resist. He did not believe it would be possible to generate speed enough to destroy the alignment of long sills. The force tends to go sideways or up, and the superstructure would break at the point of attachment to the sills. In connection with having castings provided in the structure there should be some material between the casting and the end of the sills proper to offer a resistance similar to that employed in the couplers of freight cars. There should be a dampening spring or some other provision made to absorb the shock, because of the effect on the passengers of the sudden stopping of steel cars.

J. F. H. Wyse, of the Toronto Railway Commission, said that the subject of standardization is of especial interest in Toronto at the present time, as there is now before the Ontario Railway and Municipal Board an application to lower the steps of city cars. In Toronto a number of prominent physicians have come forward and stated that high steps on the cars in the city of Toronto were injurious if not dangerous. The height of step recommended, regarding which discussion has taken place, and to abolish which an application has been made to the Toronto commission, is practically the same as that which the committee suggests in the present report as standard. In view of this condition, therefore, it would seem to him that if postponing the adoption of the proposed standards and going further into the question resulted in securing a lower standard than seventeen inches for the first step on city cars, the public's best interests would be served, an immense amount of expense to the operating companies would be avoided, and a cause removed which promises to be a source of irritation between the municipal authorities and the railway companies.

The president read a communication on the subject of the height of car steps from Howard A. Kelley, a physician of Baltimore, Md., in which he entered a protest as a physician against the seventeen-inch standard, which he considered militated against the safety and comfort of women, little children and the aged.

H. W. Blake said that the New York State Street Railway Association had gone carefully into the matter of the height of car steps three or four years ago. The conclusion had been reached that there was thirty-one inches to be made up between the ground and the platform riser. If the first step is made lower, the second must be made higher. The first step one naturally takes with the right foot, and the hand rail is in position for assistance.

Mr. Adams stated that in New York the operating companies are limited in the width across sills, which is a vital point. Cars can not be built eight feet across the sill, and consequently, clearance between sills can not be obtained to enable the radiation of a truck with thirty-three-inch sills and keep the car floor low enough to give a lower step. The New York companies do have a step somewhat lower than recommended in the report, but he would point out that there are conditions which limit the height of these steps.

The report of the Committee on Power Generation was presented by G. H. Kelsay, chairman.

This report gave particular consideration to the practical operation of steam turbines, steam meters and flue-gas analyzers. The report states that the investigations of the committee have brought forcibly to its attention the apparently indifferent methods of operation practised in many power stations, and particularly in the boiler room. The committee believes that there is far too little attention given to economy in the boiler room, and that a careful and systematic use of apparatus available would result in a great saving. It is suggested that the work of the committee be continued and that further reports should be expected next year on the question of carbon-dioxide recorders in addition to an investigation into the use and merits of draft gauges, pyrometers and systems of damper control. It is also suggested that an investigation as to the merit of buying coal on a basis of analysis should receive attention by such a committee, together with an investigation as to the methods of making analytical tests of coal and the use of calorimeters.

The report stated that twenty out of twenty-seven replies received from companies indicated that the users considered a turbine equal to or preferable to the reciprocating engine on the score of reliability, while but five preferred reciprocating engines as to this point. For operation under varying steam pressure the replies are not so decidedly in favor of the turbine, there being five out of twenty-four replies favoring the reciprocating engine. Steam-driven auxiliary equipment is preferred under most circumstances, but especially so where the exhaust is needed to heat the feed-water. The users of steam meters seem to agree that they have found the instruments valuable for test, for measuring accurately small quantities of steam, and for getting approximate divisions of steam used for various processes. Some complain of the high cost of the meters and the small variety of uses to which a given meter can be applied.

The result of the work the committee has been able to do on flue-gas analyzers indicates that these instruments are of unquestionable value, and the records, when properly taken and interpreted, offer a means of detecting defects both in the construction and operation of boiler furnaces which might not otherwise be exposed.

Charles Hewitt, in opening the discussion on this report, said that it was his experience that in the case of turbine plants and steam-engine plants equally modern and equally well designed, there was very little difference in the steam economy. An exhaust-steam turbine with a well-designed reciprocating engine would show an economy much greater than any straight turbine plant that could be built.

Mr. Roberts said that he had been surprised at the excellent performance of the turbine under excessive overload conditions. There seemed to be almost no range of power within the possibility of the strength of the material of which the turbine is constructed that it will not work up to.

R. H. Ross said that with regard to the ability of the turbine to operate under overload, that certain types of steam turbine, particularly the impulse type, give an increased efficiency under overload. The best economy with such a turbine is obtained at the greatest load that can be carried. It is to the advantage of users of this type of turbine to put on it all the load which the generator can carry without overheating.

In taking up the discussion of flue-gas analyzers, Mr. Winsor pointed out that it was customary to weigh the coal and record the electrical output, but between these two there is almost nothing to work from. Methods of knowing how coal is being burned are needed, and it is necessary to know what the boiler and what the various other units entering into the generation of power are doing.

Mr. Hewitt stated that it was generally believed that the most satisfactory point from which to take out the gas for analysis was from the stack or near the stack. He was opposed to this conclusion. In a battery of five boilers, for instance, working on one stack, it is no indication whatever of any individual boiler's performance. As a general principle, the nearer the approach is made to the stack, the less indication of carbon dioxide is found. He has discovered that the only reliable indication which can be secured is by taking a sample of gas from about the middle of the combustion chamber. Various means of abstracting the gas have been tried, and he has finally settled down to the following scheme: A pipe is run into and completely across the combustion chamber. This pipe is perforated with holes, so that a very large sample all the way across the combustion chamber is secured. He has found that the banking of a boiler in one bank materially affects the gas in the flue and in some cases it has been found that the banking of one boiler affects the other, although the other boiler may not be banked.

It was voted to accept the report and refer the subject matter to the incoming committee.

The session was then declared adjourned.

The report of the Wednesday afternoon and the Thursday sessions will be presented in the next issue.

Claim Agents' Association.

THE first session of the Claim Agents' Association was called to order by the third vice-president, J. S. Harrison, at 3.45 P. M. Monday. The president's address was read by Charles B. Hardin, claim agent, United Railways Company of St. Louis.

The report of the executive committee showed that W. H. Weh, second vice-president, had resigned because of leaving the employ of the Cleveland Electric Railway Company to engage in other business.

The treasurer reported that the total expenses were $807.89, leaving a balance on hand of $1.37 on October 1.

The Tuesday morning session of the Claim Agents was called to order at 10 o'clock, with Vice-President Harrison in the chair.

The first paper taken up was entitled "The Organization of a Claim Department for a Small or Moderately Large Company, Including a School of Instruction as a Means of Preventing Accidents," by Francis J. Ryan, M. D., Syracuse Rapid Transit Railway Company, Syracuse, N. Y.

Dr. Ryan exhibited a set of record books and forms, and explained their use.

In discussing Dr. Ryan's paper, F. W. Johnson stated that with the Philadelphia Rapid Transit Company proper instruction had brought about a marked reduction in the number of accidents.

The second paper was entitled "The Claim and Its Disposition," by Peter C. Nickel, claim agent, New York City Railway Company.

The Tuesday afternoon session was called to order at 2.30 o'clock, and the paper entitled "Uniformity in Claim Department Records and Accounts" was read by John J. Reynolds, claim agent of the Boston Elevated Railway Company.

The paper was referred to the incoming executive committee for further consideration.

An address was made by James R. Pratt, claim agent of the United Railways and Electric Company, of Baltimore, who spoke upon the advantages he had received from joining the Alliance Against Accident Fraud.

The paper entitled "The Duties of Claim Agents and Other Officials of Quasi-Public Corporations to the Public" was presented by Eugene R. Roberts, claim attorney of the Knoxville Railway and Light Company.

At the session of the executive committee held on Tuesday evening the following nominations were presented: President, C. B. Hardin, claim agent, United Railways Company of St. Louis; first vice-president, E. C. Carpenter, claim agent, Indiana Union Traction Company; second vice-president, J. S. Harrison, claim agent, Jacksonville Electric Company; Dr. F. J. Ryan, Syracuse Rapid Transit Railway Company; secretary and treasurer, B. B. Davis, claim adjuster, Columbus Railway and Light Company.

The closing session of the Claim Agents' convention was held on Wednesday morning. President Goshorn presided and stated that the amendments to the constitution and by-laws proposed by the executive committee had been considered by the executive committee of the parent association, and it had been decided to refer them for action to the 1909 executive committee of the Claim Agents' association.

The question box was read and President Goshorn described the working of the index system in his office.

The report of the nominating committee presented at the executive session on Tuesday evening was unanimously adopted.

President-elect Hardin, after a brief address, appointed the executive committee a Committee on Employment and a Committee on Ways and Means, after which the Claim Agents' convention was adjourned.

Transportation and Traffic Association.

THE American Street and Interurban Railway Transportation and Traffic Association held its technical sessions on Monday afternoon, Tuesday morning, Wednesday afternoon and Thursday morning. The first session was called to order at 3 o'clock Monday afternoon by President C. Loomis Allen. The report of this session was presented in last week's issue of the ELECTRICAL REVIEW.

On Thursday morning the following officers were elected: President, C. Loomis Allen; first vice-president, R. T. Todd; second vice-president, G. L. Radcliffe; third vice-president, A. W. Warnock; executive committee, the officers, and G. W. Parker, H. C. Page, N. W. Bolen, H. A. Davis.

TUESDAY MORNING SESSION.

The Tuesday morning session was called to order at 9.30 o'clock.

The report of the Committee on Training of Employés was presented by J. W. Brown, chairman.

This report deals with a comparison of the past and present requirements of transportation employés. The methods of procedure of a number of companies are presented in categorical form, and the report makes the following conclusion: "The committee, after careful consideration of the various methods of discipline, and with knowledge gained through actual operation of the merit and demerit system, recommends it as being the best form of administering discipline on account of its taking notice of minor infractions of rules which otherwise would not be subjects of discipline, and also because of the fact that it makes possible commendation of good work on the part of the employés. It affords, as well, an accurate record of the employé's work in every particular."

The committee also recommends that this subject be given earnest consideration, to the end that the men operating the cars and trains may be selected with a proper view of their fitness as to intelligence, acuteness of senses, physical condition and proper aptness for the work.

In opening the discussion on this report, W. H. Collins stated that his company was securing very good results by making a careful selection of its motormen and conductors and starting to train them by putting them on cars with regular motormen, and afterward giving them an opportunity to become familiar with the mechanical equipment by a special training in the shops.

P. P. Crafts stated that the Iowa & Illinois Railway Company first selected the man for his general appearance and qualifications. He then was put through a medical examination, being given a very complete test for vision and hearing and other physical and mental qualifications. If he passed the surgeon's test he was put on a car with one certain motorman and one certain conductor. The company has one man who is especially fitted for breaking in men—that is, he has the knowledge and the moral power to make a man understand what he wants him to learn. Mr. Crafts believes that the indiscriminate breaking in of car-service employés with various motormen and conductors does not result as a general thing to the best advantage of the company. It is better to have one or two men in particular who are especially adapted to this kind of work. After the man has run for such a length of time as is required by the instructor, if he be a motorman he goes into the shop for a few days to learn the essential points of the equipment. The conductor is examined to a greater or less extent as to his knowledge of ticket forms and the handling of the public, etc. After that both classes of employé are put on the extra list. The company selects from the extra list, after the summer season is over, the employés best fitted for the winter list or to go into regular service.

E. E. Potter, of Seattle, said that conditions in his city were governed a good deal by its great distance from other centres. As a consequence, there is more or less of a floating population. The Seattle Electric Company does not, as a rule, employ men who have had previous experience on other roads. The company has found that it gets better results from men who seem to possess the necessary physical and mental qualifications, training these men in its instruction school. The company has an equipment of dummy apparatus, with which the applicant is taught the necessary rules concerning signals, the working of the air devices, and the starting and stopping of cars. He is put under carefully selected motormen and conductors. Only men who have exceptionally good records and who possess the natural qualifications of instructors are picked for this work. The new man's work is carefully observed for a period of six months, and if he does not conform to a certain standard he is taken off the car and placed with a number of other men on an experimental car run over the various lines. He acts as motorman or conductor and is put through another series of tests and his work observed. The company also makes use of daily bulletins, which are posted each day, commenting, in the colloquial phrases that the carmen use, upon the good or bad work which has been noticed on the various lines. A general meeting of the men is held at headquarters about once a month, and some one from the other departments gives them a brief, interesting talk. The men are interested and secure a knowledge of the various parts of the system, the mechanical part of the car and the power stations, and the different points that there are around not only the company's lines, but other lines in the same section.

The men are also given short talks by the claim attorneys and the various inspectors.

Dana Stevens, of the Cincinnati Traction Company, stated that where his company has city and interurban lines operating from the same centre, the practice is to promote conductors and motormen from the city service to the interurban service, the principal reason for this being that the city rates of pay are lower than the interurban rates, and that by the time a conductor or motorman has become a proficient city man, he has reached a point where he will probably want the higher rate of wages which is paid on the interurban lines; therefore, he is promoted to the interurban, on which the lowest rate of pay is as high as the highest rate on the city lines. He has the privilege of staying on a city line, but if he wants to go to an interurban he can, with the prospect of advancement for time service there. Men between the ages of forty and fifty years of age are selected, preferably men with families, regardless of whether they are city or country-bred. If the man gives any local references these are seen personally. Of course, if his references are away from the city, these are written to. If the applicant is accepted he is sent to an instruction school, which is equipped with the various appliances with which he should become familiar. He is then sent to one of the different divisions, reporting to the superintendent, and is put on a car to be broken in. He works directly under an instructor until he is endorsed as competent to operate a car over the line in question. At the present time it is possible to make a very good selection of men, and in no case is a man known to be under twenty-one years of age or over forty-five selected.

R. S. Goff, of the Boston & Northern Street Railway Company, stated that in operating in ninety-five cities and towns some 930 miles of road, almost every condition is met. The employment of men is put directly up to the division superintendents, of which there are sixteen. As far as employing men who have been in other branches of public service is concerned, there is a rule that they shall not be employed except under the O. K. of the vice-president's office. The application is forwarded by the superintendent to the inspection department at Boston, the division superintendent taking care of everything local. The men are placed in service and broken in for varying lengths of time. The older men in the employ are selected for inspection service, and if it appears that a beginner does not get along properly with one instructor, he may be changed to another. In each division there are a few men who are selected for their competence as instructors. He did not agree with the other speakers with respect to the men having had city service making the best men for interurban service. He thought that it was the general opinion of the superintendents that the men on interurban service are far better if they are brought up in that class of service than if they are trained as city men.

C. E. Learned, of the Boston Elevated Railway Company, said that their procedure was very much the same as that described by the gentleman from Seattle. Instead of taking the extra man off a car and showing his deficiencies to the other men on the road, he is quietly instructed by a special instructor. The instructors receive ten cents a day extra for their service the year round, whether they break in a man or not.

J. E. Duffy, of the Syracuse Rapid Transit Railway Company, stated that one of his companies operates three systems: one a purely city system, one an interurban operating for thirty miles between two cities, and the other a city and interurban. When the interurban line was started—an electrified steam road of the West Shore Railroad between Syracuse and Utica—the question of providing men for this service came up. The management decided to take the old men from the two city lines and train them for interurban service. The selection was left to the superintendent of the two ctiy companies. The men were entirely unfamiliar with high-speed equipment and block signals. They were first placed in the shops when the cars were being assembled, and were paid the regular rates of wages while they were receiving instruction. There were forty-two men in the first instruction classes, and it cost the company approximately $7,800 to instruct the men necessary to man the cars. The experience of the company was entirely satisfactory in the matter of promoting the men from the city service to the interurban service, and he believed that the management was quite satisfied with the expenditure of the money.

E. F. Peck, of Schenectady, pointed out the importance of having the men subjected to a written examination. When an accident happens the men very often profess great ignorance, and the local papers take advantage of this fact to noise about a cry that the men are unfamiliar with the rules.

Mr. Duffy said that his company had felt the necessity which Mr. Peck pointed out, and that the Syracuse company took 450 of its employes and paid them for the time that was consumed when making out a written examination. This examination was placed with their record, and all men hired since that time are compelled first to pass an oral examination, which the instructor verifies in writing, and then a written examination, which the applicant signs.

The Hon. W. Caryl Ely addressed the meeting, and called attention to the fact that the present very efficient condition of the organization was an evidence of the fact that the American association is doing a useful work and a lot of it. He thought that there would be a tremendous amount of good obtained by the members of the Transportation and Traffic association from the meetings, and that the emoluments for work will constantly become greater as men become more efficient. It seemed to him that there never was a time when the opportunities were so great as they are now. He called particular attention to the fine series of pictures illustrating the Inland Empire System. Thirty years ago there were no buildings where the Shoshone Flyer now runs, and to-day in the state of Washington there are less than a million people. In spite of this in thirty years there has been the most extraordinary development.

The paper entitled "The Carrying of United States Mail on Electric Railways—Its Advantages and Disadvantages, and the Compensation Therefor," was presented by C. H. Hile, assistant vice-president of the Boston Elevated Railway Company.

After a brief discussion of this paper by J. T. Choate, the convention was adjourned until Wednesday morning.

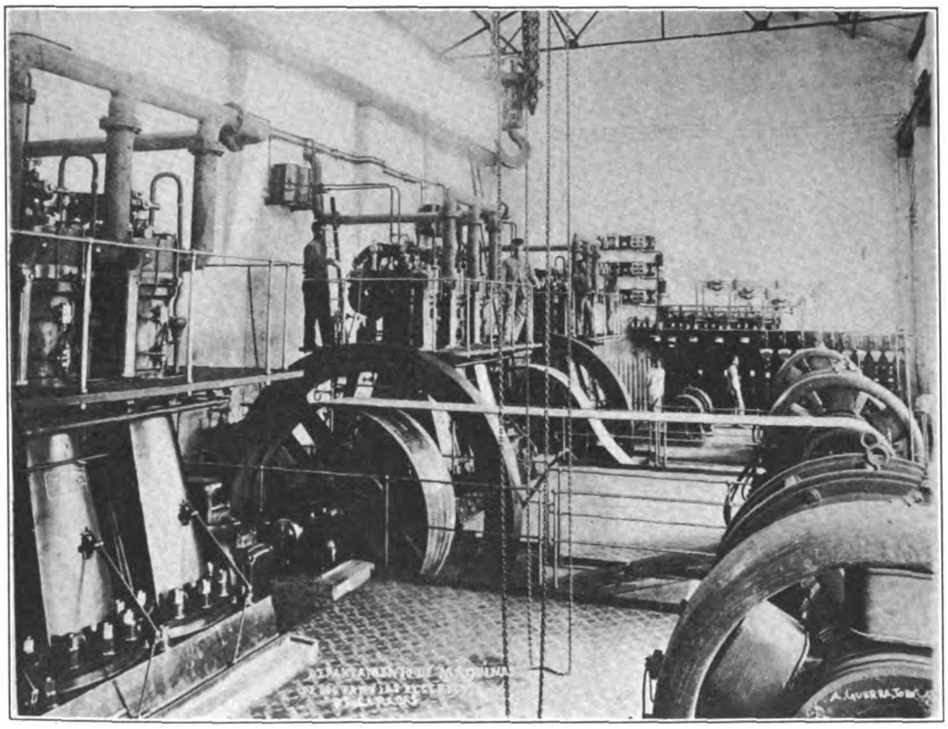
The report of the concluding sessions will be presented next week.

THE ELECTRIFICATION OF THE CARACAS (VENEZUELA) TRAMWAYS.

MODERNIZING ONE OF THE OLD SOUTH AMERICAN CAPITALS.

Caracas, the capital of Venezuela, South America, is the ninth in size of the twenty capitals of America. Caracas was founded by Diego de Lazada in 1564, some sixty years after the settlement of La Guaira, only ten miles away on the coast. The history of the town has been the general history of the Spanish Main. Within twenty years of its foundation the city was raided by Amyas Preston and again later in 1595 by Drake. From 1810 to 1872 there were almost constantly at least two, and sometimes more, opposing armies in the field. In 1872 Guzman Blanco came, took the presidential chair, and with him arrived a comparatively golden age for Venezuela. In 1888 the dictator, who was living in Paris, was formally deposed, and from that date revolution succeeded revolution. The reigning president, Cipriano Castro, won the supremacy in 1899, and has since held his own in spite of efforts, both internal and external, to dislodge him.

Caracas, as has been already stated, is a town of red and white roofs, in squares. It is, in fact, built, as far as the configuration of the ground permits, on the American chess-board system.



Caracas Tramways. Engine Room.

Previous to the year 1905 there were two small horse companies in operation, the Bolivar, running east and west from the station of the Central Railway to that of the La Guaira and German lines. The other was the Caracas Tramway Company, which, starting from the Plaza Bolivar, radiated out to the different quarters of the city. In 1905 the two companies were combined under the presidency of Dr. Zuloaga, a leading member of Caraquenian society, and the directorship of Edgar A. Wallis and Albert Cherry, two of the most prominent members of the British community. A concession was obtained from the municipal authority with a view to the electrification of the whole system, and E. H. Ludford, formerly manager of the Bolivar company was appointed general manager of the whole. Mr. Wallis then went to London, where he speedily interested English capitalists in the scheme, on which J. G. White & Company, Limited, drew up a full report. Their recommendations were accepted and a contract was drawn up, whereby J. G. White & Company, Limited, undertook to supply a complete equipment, including track, office buildings, car-shed, power-house and plant and cables. Work was started in the spring of 1907 and completed by February, 1908.

The routes selected, with a total length of ten miles, were practically those of the old companies. These naturally converged into the Plaza Bolivar, the centre political and social of the city, in which and around or near which all the ministerial and government buildings are situated. The principal line is that from east to west, uniting the Central Railway with the La Guaira stations. On the north side are three routes. Of these the Pastora runs to the northwest through a fashionable district; the Avenida Norte to the Hospital Vargas, past the Panteon where are the ashes of the heroes of the independence, Bolivar and Sucre, and a monument to Miranda; while the third, the San José, parallel to this, but further to the east, runs through a working-class district to the northern boundary. On the southern side are three routes, one to the southeast to the Ponte de Hierro, where the track crosses the Guaira River and connects with a light tramway to a suburb, three miles out; a second to the due south; a third to the southwest. The last divides into two, of which one crosses the La Guaira and the other, the Palo Grande, connects with the German line at a station of that line. Besides tapping a large and populous quarter of Caracas, the Palo Grande line forms the connecting link of a chain of railways of uniform gauge stretching some 180 miles from Pto. Cabello, an important growing port to the west of La Guaira, passing through Valencia, the city second in size and importance in the north of Venezuela, and traversing Caracas, travels toward the south by the Central Railway. By the route also the Caracas meat supply is introduced into the city, the abattoir being situated a short distance from the Palo Grande Station. The maximum gradient is four per cent.

The rails are in thirty-foot lengths and weigh eighty-seven pounds to the yard, and were supplied by the United States Steel Products Export Company. They are of a pattern made especially to suit South American requirements. The tie-bars are of the Bayliss, Jones & Bayliss type. The rail are of the continuous pattern. The rails are of the continuous stringer, sixteen centimetres deep by forty-seven centimetres broad, and are anchored every fifteen feet. The paving is of four kinds—cobbles, setts, macadam and concrete. The special work was manufactured by the Hadfield Steel Foundry Company, Limited, of Sheffield. All points are automatic and of the best toughened cast steel with manganese tongues. They are ten feet six inches in length and have a centre radius of 100 feet. The mates are of solid Era manganese steel, and the rails are bonded with 0000 Brown & Sharpe concealed bonds, supplied by the United States Steel Products Export Company. The fact that no general drainage system is in use in Caracas, and that the drains in existence are principally private property and close to the surface, caused considerable hindrance to the otherwise rapid progress of the work.

The bulk of the overhead construction consists of side poles with cross bracket arms. The junctions are formed with 7/12 galvanized steel span wire, with a breaking strain of 4,000 pounds per square inch, supplied by W. F. Dennis & Company. Only tubular poles are employed, of which 450 are of the Grand National type, their dimensions being seven and five-eighths inches diameter, bottom section, six and five-eighths inches in centre and five and nine-sixteenths inches top section, and thirty feet in length. The rest of the poles are thirty-one feet in length and are of British standard pattern. All were supplied by Messrs. Stewarts & Lloyds. The bracket-arm tubes are two and three-eighths inches diameter. The feeder boxes, supplied by Estler Brothers, are three in number, being fitted with 250-ampere quick-break switches; the section boxes, fourteen, with 100-ampere quick-break switches. The trolley wire is of the 00 Brown & Sharpe grooved type.

The feeder cables, some four miles in length, are all aerial, and are suspended from cross-arms on the poles above the brackets. They are all of pure aluminum with a size of 0.33 and 0.25 square inch, and have a conductivity sixty per cent of that of copper wire, with a conductivity of ninety-nine per cent of Matthiessen's standard of pure copper. They were supplied by the British Aluminum Company and covered by the Silvertown India Rubber & Gutta Percha Company, with triple-braided weatherproof insulation and compounding over all.

The power-house, office buildings and car-shed are all built on one site on the north of the Avenida Este. The plot is rectangular and with a frontage of 53,870 metres and a depth of 43,520 metres. They are all of brick with steel girders and roofwork obtained from Brown, Duncan & Company, of Bootle. The roof coverings of the power-house and car-shed are of galvanized iron, but the office buildings and manager's dwelling are tiled. The doors and window frames are of cedar.

The car-shed is situated at the back. Its dimensions are thirty-five metres by 12.34 metres, and its walls are six metres in height. It contains five tracks, two of which have a pit and are supported on iron columns. The floor and pit are concreted. The rails in the entrance and car-shed are the American Society of Civil Engineers seventy-pound tee rail, and the paving at the car-shed entrance is cobble.

The frontage is taken up with the office buildings and the power-house, over which is the manager's dwelling. The office buildings are all on the ground floor and cover an area of thirteen metres by eleven metres. It is subdivided into manager's, clerks' and accountants' rooms, and men's waiting room, and is provided with lavatory fittings by Doulton & Company. The first story has been arranged to serve as a residence for the manager of the company, who can thus exercise the unusual close supervision requisite in training an inexperienced staff. The roof over the shops was also adapted to serve as a roof garden, providing a cool and pleasant place of retreat in the tropical evenings. The rest of the road frontage is taken up with the engine room, with a length of forty-four metres and a depth of eleven metres and a height of ten metres, while behind the engine room is the battery room, with a floor area of nineteen metres by seven metres, and the machine, carpenters' and other needful shops, the whole making one compact and self-contained system.

There are two aspects from which the power-house may be regarded, either as a substation for a high-tension current or again as an independent producer. As a substation it is employed to transform from 4,500 to 500 volts. The high-tension alternating-current is obtained from the electrical company of Caracas. This company has two stations, at Encantado and Los Naranjos, about sixteen kilometres from the capital. There are four generators at each station and more machinery is now being introduced. The motive force is the water of the Guaira River, which has a fall of thirty-eight and one-half metres and 154 metres at Encantado and Los Naranjos, respectively. During the day the power is supplied by the electrical company.

In the evenings, however, when the town is lighted electrically, and also during stoppages which may occur occasionally, the power is produced in the power-house itself. This is effected by three Diesel engines of 240 brake-horse-power each, running at 180 revolutions per minute. The Diesel engines were selected on account of the high price of coal. They have, moreover, an additional advantage in that no delay need occur in starting them, an advantage which is obvious in the case of a sudden interruption of the high-tension transmission. The engines are belted to three motor-generators. On the induction-motor side these are designed for 5,000 volts, three-phase with fifty cycles, while on the direct-current side they yield an output of 150 kilowatts at 550 volts at a speed of 500 revolutions per minute. The station is also furnished with a battery of 260 Tudor cells, with a

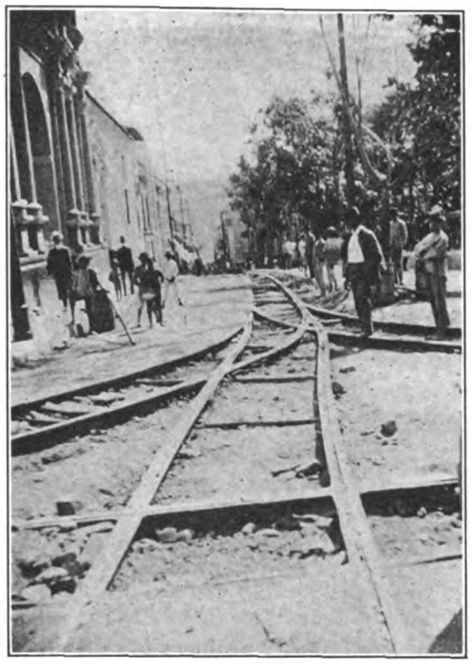
Caracas Tramways. Exterior View of Offices and Manager's House with Engine Room Adjoining.

capacity of 520 amperes for one hour and 252 amperes for three hours, the maximum charging current being 252 amperes. The Lancashire Dynamo and Motor Company has supplied one of its automatic reversible boosters. The regulation with the battery and booster is such as to keep the load on one or two generators operating in parallel (*i. e.*, 150 kilowatts or 300 kilowatts at 550 volts) constant within eight per cent over or under the normal load of 272 or 544 amperes, provided the maximum load does not exceed 100 per cent of the normal load of the set or sets running. In case of 150 per cent overload, the variation does not exceed ten per cent and in the case of 200 per cent overload the variation does not exceed twelve per cent.

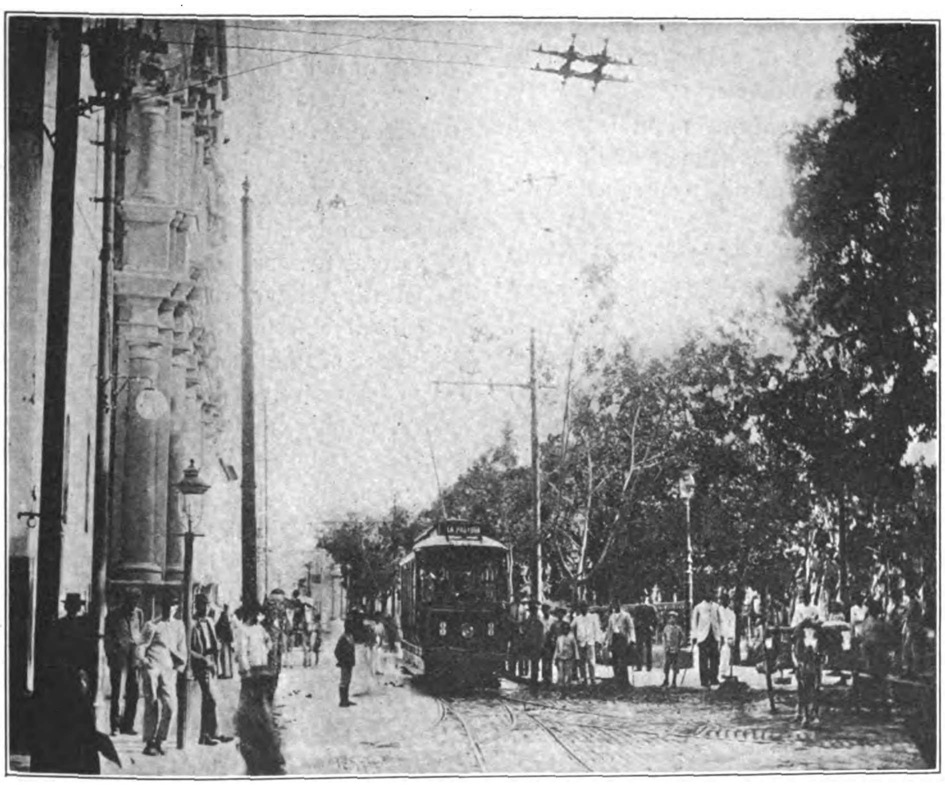
The switchboard consists of ten panels, *viz.*, one high-tension incoming feeder panel three-phase, 5,000 volts between wires. Three induction-motor panels, one battery and booster panel, three direct-current generator panels and two feeder panels, all fitted with the necessary instruments. The board and motor generators were supplied by the General Electric Company, of New York.

The cars, thirty in number, each with a seating capacity of thirty-two, are of the open single-deck type. The car bodies were supplied by Miles, Voss & Company, Limited, of Birkenhead.

The body framing and flooring are of teak and the roof of aluminum. The seats are of the garden-seat pattern, four being reversible and four stationary. They extend transversely the whole width of the car. Storm curtains are provided at the open sides. There are destination indicators and also lifeguards of the Hudson and Bowring type at each end of the car. The trucks are all of the Brill pattern and were manufactured by the United Electric Car Company, Limited.



Caracas Tramways. Special Work, Under Construction.



Caracas Tramways. Construction at the Cathedral Corner of Plaza Bolivar, Central Square of the City.

The electrical equipment of each car is composed of double-motor GE-58, four-turn, thirty-seven-horse-power for 500 volts. It includes also two B-18 controllers with one set of handles, magnetic blowout circuit-breaker, etc. With a view also to the sharp street corners and heavy gradients, each car has in addition to the mechanical brake one Westinghouse magnetic track brake.

From the commencement of the work by J. G. White & Company, Limited, under the supervision of J. G. Rose, in March, 1907, to its completion in February, 1908, the ordinary horse-drawn tramway traffic was in full operation. The traffic and construction were so arranged that during the whole period of conversion little, if any, diminution, took place in the receipts of the tramway company.

Meeting of the American Society of Mechanical Engineers.

The November meeting of the American Society of Mechanical Engineers will be held in the Engineering Societies Building, 29 West Thirty-ninth street, on Tuesday evening, November 10. Franklin Phillips, president of the Hewes & Phillips Iron Works, Newark, N. J., will make an address on "The High-Powered Rifle and Its Ammunition—Instruments of Precision," illustrated by lantern slides.

Mr. Phillips is an expert marksman, and in 1903 won the position as first alternate on the international rifle team to England. He was for many years chairman of the committee on rifle and pistol practice in the National Guard of New Jersey, and is now ordnance officer of the Second Infantry of that state.

Tests of rifles and ammunition at Sea Girt, N. J., by men connected with the New Jersey National Guard have led to marked improvement in arms and ammunition and to an entire change in the powder used by the Government, thereby greatly increasing the accuracy of the shot. The improvement has been extended to large guns, and instead of two per cent hits which were made at Santiago, eighty per cent is now the average in some ships.

Mr. Phillips has actively participated in this work, and as he is primarily a mechanical engineer, as well as a marksman, he will explain to his audience the practical bearing of his investigations upon the construction of arms and the elements entering into ammunition.

THE INTRINSIC BRIGHTNESS OF LIGHTING SOURCES.[1]

BY J. E. WOODWELL.

The importance of intrinsic brightness as a factor in practical illumination has been long appreciated and strongly emphasized. At no time has this factor been more essential from the standpoint of hygiene of the eye than the present. The opportunities for violation of the laws of hygiene have not only been enlarged but the penalties of such abuses have been greatly augmented, with the general introduction of the more recently developed lighting sources of high intrinsic brightness, such as the metallic filament incandescent lamps, flaming arc lamps and high-pressure gas lamps. In too many of the recent installations the most dazzling gas and electric lamps are ruthlessly placed in such positions that the eye can not escape the glare. Moreover, the distressing brightness of the source is often intensified by the improper use of concentrating reflectors.

Briefly, any brilliant source of light in the field of view, however small, causes a contraction of the pupil of the eye and reduces the effect of illumination received from other parts of the visible field. A contraction of the pupil also takes place even if the bright spot is viewed only occasionally. Furthermore, the continuous or occasional presence of a bright light source in the field of view impairs, temporarily at least, the sensitiveness of the eye itself, thus again reducing the effectiveness of illumination. Moreover, the contraction of the iris in the presence of bright light sources soon reaches the limit of its protective faculty, beyond which it responds feebly to an increase in brightness. The control of the pupillary aperture appears to be designed to strengthen the vision under comparatively weak illumination, rather than to protect against excessive intensity or brightness.

Recent researches of André Broca and F. Laporte[2] indicate that the pupillary contraction caused by bright light sources within the peripheral vision reduces visibility in proportion to the decrease in working illumination and produces the greatest eye fatigue in comparatively weak illumination. The exhaustion and injurious effect was greatly reduced on the other hand under an illumination of from 1.86 to 3.72 foot-candles, which was shown by tests to be favorable for work, taking into consideration the physiological properties of the eye and the mean limits of its accommodation.

The intrinsic brightness of the luminous source rather than the distance of the source from the eye was shown to be the principal cause for pupillary contraction. This same careful investigation also made it evident that the different light sources may be classed—with reference to their action in producing pupillary contraction and residual images—in the order of their respective intrinsic brightness.

The researches referred to above as well as other previous investigations do not indicate that the protective faculty of the eye is susceptible to the energy effect or to light rays of different color.

Ultra-violet rays have been regarded by some authorities as harmful, but it has been shown that these rays in the light from various forms of incandescent illuminants of high intrinsic brightness are with few exceptions, much less than in direct or even reflected sunlight. Other invisible radiation of much more harmful character may accompany not only the newer light sources of high incandescence but those of lower temperature as well.

The more important hygienic effects of light sources of high intrinsic brilliancy within the field of vision may then be summarized as follows:

1. Contraction of the pupil is caused, thereby reducing the amount of light entering the eye and the consequent visibility.

2. The sensibility of the visual organs is temporarily impaired by residual images and retinal fatigue.

3. The effects of (1) and (2) are also produced by the occasional view of bright sources or by subjecting the eye to sudden fluctuations of light.

4. Intrinsic brightness rather than the distance of the source from the eye is the principal cause for pupillary contraction.

5. The harmful effects are greatest in proportion to the decrease in the working illumination and are considerably reduced under an illumination exceeding two foot-candles.

6. The different luminous sources may be classed with reference to producing pupillary contraction and after images in the same order as their respective intensities.

In applying the knowledge of the laws of hygiene of the eye to the design of artificial illumination, the best criterion of the proper values of intrinsic brightness of the light source, as well as of other essential factors, is daylight.

The intrinsic brightness of nearly all of the artificial light sources being so much higher than that of natural daylight is the principal cause of eye-strain and wear and tear on the visual organs. Even the most successful efforts to secure diffusion in artificial illumination by the so-called indirect method can not be compared with the diffusion of daylight. From this point of view diffusion is the most important single quality of daylight. Diffusion may be obtained in artificial illumination by enlarging the area or surface of the light source, by shading the source with diffusing globes or screens, or by concealing the source and utilizing the diffuse reflection of the surfaces which receive the direct light.

The intrinsic brightness of a light source is the candle-power or intensity of the source divided by the area of the luminous surface. The intrinsic brightness of a small surface is the candle-power perpendicular to the surface divided by the area of the surface. Intrinsic brightness is stated, therefore, in candle-power per square inch, or in hefners per square centimetre when metre units are employed.

Measurements taken by Basquin show a mean annual brightness for zenith sky in Chicago of 500 candles per square foot, or about 3.47 candles per square inch, with a range from 200 to 1,100 candles per square foot according to the month and other conditions. Making due allowance for the decrease in brightness near the horizon for natural reasons, and the reduction of the effective sky area by buildings and other local objects, the virtual intrinsic brightness of the sky in relation to the flux of light received through an ordinary vertical window, under average conditions probably rarely exceeds one-fourth of the above figure.

Measurements of the daylight illumination received in rooms at various distances from a window fitted with a ground-glass screen indicate also that the vertical brightness of the flux of light from the sky, direct sunlight excluded, though varying widely under different conditions, is not often more than one candle-power per square inch. Even such a comparatively low degree of brightness exposed to view affords discomfort to the eye. Shades and screens are depended upon to modify all but the most moderate natural brilliancy so that with a satisfactory interior illumination the virtual intrinsic bright-

[1] Abstract of a paper presented to the Illuminating Engineering Society, Philadelphia, Pa., October 5-6.

[2] Étude des principales sources de lumière au point de vue de l'hygiène de l'oeil. MM. André Broca et F. Laporte. *Bulletin* of the Société Internationale des Électriciens, vol. viii (2d series), No. 76.

ness of the flux of daylight through windows may be as low as 0.1 or even 0.01 candle-power per square inch.

Even an abnormally high illumination of ten foot-candles on a white diffusing surface, such as white blotting paper, gives an intrinsic brightness of the surface very little more than 0.005 candle-power per square inch, neglecting absorption which would reduce the apparent brightness to 0.004 candle-power or less.

Compared with such figures the intrinsic brightness of all of the naked artificial luminous sources is enormously high, while the values secured in actual practice by the use of shades and diffuse reflecting surfaces are generally more than ten times as great.

A number of authorities regard four or five candle-power per square inch safe and admissible and one or two candle-power good practice. While the use of even the lower of these values in artificial illuminations is questioned, it would result in a most pronounced improvement from the hygienic standpoint and alleviate one of the principal causes of eye-strain and fatigue.

Acid-frosted or sand-blasted incandescent carbon or metallized-filament lamps as commonly used in exposed positions without reflectors have an intrinsic surface brightness of from 0.75 to 1.0 candle-power per square inch. When in the field of vision, however, such frosted lamps frequently produce a most distressing and harmful result, and reduce the value of the effective illumination.

In consideration of the foregoing data, as well as from actual experience in the design of illumination, it is the opinion of the writer that from 0.2 to 0.1 candle-power per square inch is none too low for the safest and best practice where artificial sources must necessarily be placed in the constant or even occasional field of vision. The use of such a factor is necessarily dependent upon the local conditions and especially upon the intensity of general illumination of the objects viewed and the corresponding pupillary aperture, as noted by Broca and Laporte.

In the presence of a highly illuminated field of view the iris diaphragm of the eye is "stopped" down almost to a minimum, and the direct effect of any light sources within the field of vision is correspondingly lessened. These conditions occur in practice where a room or space is almost uniformly illuminated by exposed lighting sources of high brilliancy and there are neither dark surfaces, sharp contrasts nor shadows which would require the eye to work with a larger pupillary aperture. Such conditions, while tending to reduce the deleterious effect of brilliant light sources, are not the most favorable for best vision. Working in such an environment it is not strange that a comparatively high intensity of illumination in foot-candles is frequently demanded and the eye appears insatiable. From the standpoint of efficiency, therefore, as well as of hygiene, the conditions must favor a pupillary aperture which is sufficiently large to work the eye at its maximum sensibility. To accomplish this result the intensity of illumination should not only be moderate, in general from 1.5 to four foot-candles, but the intrinsic brightness of the sources should be reduced to 0.2 or 0.1 candle-power per square inch; or else the sources must be completely excluded from the field of vision.

With a weak illumination, however, requiring the eye to work at or near the limit of opening of the pupillary aperture the eye is extraordinarily sensitive to the direct light from sources of even moderate intrinsic brightness, and under such circumstances the actual apparent surface brightness of the source can not be kept too low for safety. This point is illustrated by the distressing effect of frosted and shaded lamps, and sometimes of candles, in the field of vision under the conditions of a weak general illumination frequently found in theatres, churches and auditoriums.

It is possible that the effects of overstimulation by means of varying intrinsic brightness has some such relation to the pupillary aperture through the range of accommodation of the eye as that of the ability of the eye to note a constant fractional difference in luminosity through a wide range of intensities of illumination, according to the law of Fechner.

The distance of the luminous source from the eye within the limits ordinarily found in interior illumination does not appear to be material, except in its relation to the position of the source and its inclusion or exclusion of the field of vision.

The preceding discussion has been confined to the direct effects and modification of the intrinsic brightness of luminous source, but it is evident that the same conditions will apply equally well to the reduction of the intrinsic brightness of all illuminated surfaces which become secondary sources of illuminations. Even with indirect illumination the ratio of brightness of the reflecting surfaces to that of the illuminated field may be excessive.

The foregoing data will have their principal application, however, in the design of globes and shades which are commonly employed to reduce the intrinsic brightness of exposed lighting sources. In arriving at the resultant intrinsic brightness it is necessary to refer to the spherical candle-power of the source and to make allowance for the absorption by the glass which may vary between from fifteen to twenty-five per cent for alabaster to sixty per cent or more for opal or porcelain glass. The absorption by ground glass will vary according to the process employed in roughing or sand blasting, but it will generally be between twenty and forty per cent. The thickness as well as the quality of the glass will also have a marked influence upon the absorption. Moreover, the distribution of the light from this source will be modified by surrounding the lamp with an inclosing globe. The most perfect diffusion will be received by a ground opal glass, but at a sacrifice of from forty to sixty per cent of the total light. The more transparent glasses, on the other hand, do not sufficiently diffuse the light from the source. In any event, however, it is important that the size of the diffusing globe or shade should be proportioned to the candle-power of the source, so that the reduction of intrinsic brightness will be approximately uniform. Fixture designs employing exposed frosted lamps together with other lamps in large inclosing globes of comparatively low intrinsic brilliancy are especially objectionable.

Belgian Electrical Industry.

Consul-General Ethelbert Watts announces that in the Brussels district of Belgium there are several underground tramway lines worked by two different companies. The companies employ their own staffs for their construction work.

The work of laying the underground telephone system is carried out on the contract plan.

A concession for an electric tramway has just been granted in Namur.

Projects are under way for electric lighting plants at Anderlecht, Etterbeek, Auvelais and Montaigu.

The Electric Club of Chicago.

The Electric Club of Chicago was addressed, at a meeting held on October 14, by W. J. Warder, Jr., of Roth Brothers & Company, on the subject of "Direct-Current Elevator Motors." On October 21 the club was addressed by W. T. Dean, of the General Electric Company, and next Wednesday the address will be made by Peter Junkersfeld, of the Commonwealth Edison Company.

Illuminating Engineering Society—II.

Report of the Second Day's Sessions of the Convention Held at Philadelphia, Pa., October 5 and 6.

(Concluded.)

TUESDAY MORNING SESSION.

THE first paper taken up Tuesday morning was entitled "Intensity of Natural Illumination Throughout the Day," by Leonard J. Lewinson. This dealt with the intensity of illumination produced by natural sources of light, such as the sun, moon and stars, modified by the earth's atmosphere. Experiments were undertaken to secure data under various atmospheric conditions at different periods during the day. To make a complete survey of the subject would involve years of effort. A problem which is open to discussion, and which is of much importance can be summed up in the question: Why does the human eye, which is satisfied with an illumination of two foot-candles produced at night by an artificial source, require at least twenty foot-candles of daylight for ordinary reading purposes? Two Sharp-Millar photometers equipped with miniature tungsten lamps were used. The experiments were conducted on the roof of the Electrical Testing Laboratories in New York city, where there was practically no obstruction to the light from the sky. Tables and curves were given, showing the variation of the intensity of natural illumination. Considering first the night illumination, it was noted that the sky light value approximates one-one-thousandth foot-candle when the moon is not visible. The rate of illumination during the hour preceding sunrise is enormous. When the observation was made, at 5.25 A. M., about seven minutes before sunrise, the illumination was 10,000 times that at 4.25 A. M. During the hour after sunrise the rate of increase is relatively small. When the sun first appears above the horizon the horizontal illumination is about equal to the normal. After the sun is well above the horizon the normal illumination increases more rapidly than the horizontal. During the later morning hours there is a steady increase of both horizontal and normal illumination. A correspondingly regular rate of decrease is noticed after noon and until 6 o'clock, when the falling off becomes more marked. A fair average figure for horizontal illumination produced by moonlight and sky light on an ordinarily clear night is about fourteen-thousandths foot-candle. The daylight illumination varies in intensity from 2,000 to 8,000 foot-candles between the hours of 8 A. M. and 4 P. M.

The discussion was opened by Carl Hering, who remarked that it seemed apparent that we should adapt our artificial illumination or night illumination to correspond with daylight to make the best use of our eyes. It might be of interest to know that the maximum illumination obtained—12,000 foot-candles—corresponds to the intrinsic brightness of the Welsbach mantle. He did not care to assume any responsibility for the data, but he pointed out that if the conversion factor of 452, by which the candles per square inch are multiplied, are reduced to foot candles, it would indicate that a piece of paper exposed to daylight is as bright as a Welsbach mantle. If the figures are correct this is the case.

J. E. Woodwell raised the question whether the two values indicated here—that is, the horizontal component and the normal component—were as important as the vertical component, as practically all of the light which enters modern structures comes in through vertical windows. In future work of this kind he would suggest that measurements be made of the vertical component of illumination, and that data be secured concerning the effect of the reflection of the exterior walls and buildings upon street lighting.

Emile G. Perrot said that he had made a number of observations concerning the relative efficiencies of daylight at various times of the year. The test described, being made in September, he thought did not give any real value from a practical standpoint in designing a building, for the information that is really required by the architect should cover the entire year, as the illuminating value of the sun changes all the year round. We must remember that the sun in winter is lower in the horizon than in summer, and consequently the penetration of the sunlight into a room in the vertical plane would be greater in winter than in summer. Again, the sun sets and rises in different positions at different times of the year, so that the position of a building may be right for one time of the year and wrong for another.

A communicated discussion of this paper by R. S. Hale called attention to the fact that it is evident that in street lighting the intensity of illumination in the morning daylight, say, an hour before sunrise, is higher than the same time in the evening daylight, say, an hour after sunset. For that reason he considered that municipal schedules for street lighting can be regulated to economize in the use of artificial light in the early morning hours. He also called attention to the physiological effect upon the retina of the eye of a person who has been working at night out in the open. The retina is more extended in the morning hours, so that it takes in more of the reflected light than it does at any other time.

In closing the discussion Mr. Lansingh stated, in answer to Mr. Woodwell, that there was considerable question with regard to the measurement of ordinary illumination. It was hard to decide which way to turn the photometer—whether away from the sun, or toward the sun, or at an angle. Measurements will probably have to be made in a great many planes, and the paper was simply an introduction to the subject. He would point out, however, that all measurements of illumination made during the day would be measurements of the sunlight plus the sky light.

The paper entitled "The Integrating Sphere in Industrial Photometry," by Dr. Clayton H. Sharp and Preston S. Millar, was read by Dr. Sharp. This paper described the integrating sphere, sometimes known as the Ulbricht sphere, which was first put into practical form in 1900. It consists, briefly, of a hollow sphere containing the source of light, and coated inside with a white diffusing paint. Into the side of the sphere is set a small window of diffusing glass, the brightness of which, when the direct rays are screened from it, measures the total luminous flux within the sphere. The theory of the integrating sphere is as follows: If a source of light having a uniform distribution of candle-power is suspended at the centre of a hollow sphere, the illumination at any point on the surface of the sphere is proportional to the mean spherical candle-power or to the total luminous flux of the source. If, however, the source be moved away from the centre, this relation no longer is true. If the interior of the sphere is coated with a white diffusely reflecting coating, obeying Lambert's law, the illumination at any point of the surface may be regarded as being made up of two component parts: first, that due to the light falling on it directly from source; and, second, that due to reflection from all other sources of the surface of the sphere. During the past two years experiments have been made with integrating spheres at the Electrical Testing Laboratories in New York, with uniformly favorable results. In using the integrating sphere reliance must be placed in the substitution method of photometry. The sphere may be used in conjunction with existing photometric apparatus. At the Electrical Testing Laboratories an eleven-inch sphere has been used with small lamps. A thirty-inch sphere is used with a simple Lummer-Brodhun photometer. An eighteen-inch sphere and an eighty-inch sphere are used with a convenient type of portable photometer.

The discussion was opened by Francis E. Cady, who asked whether any investigation had been made of the effect of the collection of dust or dirt on the inside of the sphere on the diffusing surface.

H. Thurston Owens asked if this type of photometer had been used for gas lamps, such as gas arcs.

Alfred A. Wohlauer asked whether the theory of the integrating sphere could be applied to the precalculation of the illumination due to reflection from walls or ceilings.

In closing the discussion, Dr. Sharp said that they had made no investigation with regard to the effect of dust, because the simplest thing to do was to take the dust off.

As to the measurement of large gas lamps, this would undoubtedly be entirely feasible.

With regard to the measurement of large reflecting surfaces, Dr. Sharp did not quite see the direct connection between the constants of the sphere and the constants of the rooms when measuring the light reflected from walls and ceilings.

The paper entitled "The Ives Colorimeter in Illuminating Engineering" was read by Dr. Herbert E. Ives. This paper described the Ives colorimeter, designed by Frederick E. Ives for the measurement of all colors in terms of three primary colors. By means of the colorimeter it is possible to describe a color accurately in terms of the red, green and blue components of a standard white light. For instance, in place of the indefinite term "pink," a color may be designated as red, sixty-two; green, thirty-one; blue, fifty. These figures mean that by mixing red, green and blue light in the proportions given, there is produced to the eye the sensation of pink. Two colors alike to the eye measure alike in the colorimeter. In this it differs from the spectrophotometer, which gives the intensity at every point in the spectrum, but only an approximate indication of how the eye will compare the color in question with another. A table was read showing the red, green and blue readings of various sources of illumination. From the observations made it would appear that the best light for matching colors is that of the Welsbach mantle, while that of the Cooper Hewitt lamp—an extremely selective source—exhibits wide deviations.

D. McFarlan Moore opened the discussion on this paper, and stated that in his opinion the light from the carbon-dioxide tube should be given the first place in its approximation to daylight. From the paper he would draw the conclusion that the mercury arc would be preferable to a carbon-dioxide tube over a ribbon counter in a drygoods store. This statement, he said, was misleading. As a substitute for natural light the carbon-dioxide tube was superior to all others. He quoted the results secured by a number of authorities, which would indicate that the spectrum of the carbon-dioxide tube, when passing an electric current, differed very slightly from daylight. Mr. Moore called attention to tests carried out by Professor Utzinger for the Siemens-Schuckert Company in Germany. The figures obtained in these tests differed very materially from those given in the paper. Professor Utzinger makes the statement that the carbon-dioxide tube does not differ from daylight more than three per cent on a cloudless day. Mr. Moore also took exception to the method which was used in effecting a comparison of the illumination of the tubes in the New York Post Office, upon which the data given in the paper were based.

Dr. E. P. Hyde explained the circumstances under which the tests were made. Every precaution was taken to secure an accurate reading, and he felt convinced that the figures given by Dr. Ives were not far from correct.

Frederick E. Ives stated that he had made the tests described in the paper, and that direct comparison was made with the light from an electric lamp. It seemed to him that the carbon-dioxide tube comes nearer to daylight than any of the other artificial illuminants used in these tests. His impression was gained perhaps because of the steadiness of the light and because it was rich in blue lines. He thought that it represented the color of a rather blue sky than average daylight.

E. L. Elliott stated that he had the greatest admiration for the work of Dr. Ives, and that it was reasonable to expect something very practical in the way of color measurements; but to put the carbon-dioxide tube as bluer than the mercury lamp introduced a discrepancy which it seemed to him was too large to be explained away. He did not know of any light sources which had been introduced for commercial use which were wider apart in their appearance, and an instrument that would confuse these things would not be of the most reliable character.

Dr. Hyde, in answer to Mr. Elliott, stated that during the time of the test three observers had stood in the room and had in perspective the carbon-dioxide tubes and the mercury-vapor tubes. The consensus of opinion was that, of the two sources, the carbon-dioxide tube was slightly bluer and the mercury-vapor tube slightly greener. The conclusion was that there was very little difference in the integral result—that is, in the apparent color, and it so happened that the data, when worked up, confirmed the observations made on the spot.

The paper entitled "Calculating and Comparing Lights from Various Sources" was read by Carl Hering. This paper was an attempt to clarify the apparent mistiness surrounding many of the calculations of light by giving the formulæ in such form that they can be directly used for numerical calculations, and to explain in plain terms some of the less usually understood, but often very useful, and perhaps not generally understood laws. It was also an attempt to show what the real physical meaning is of the various quantities involved, so that they may be used more intelligently. The paper proceeded to throw into the form of equations the fundamental relations existing between the various factors involved in the calculations, and also gave graphical demonstrations of the methods by which these relations were arrived at. Eliminating literal factors, the conclusions were represented directly by the physical name given to the terms involved in the equations.

Dr. Sharp discussed this paper at length from the point of view of its definitions, and called attention to the necessity for caution in accepting the dicta laid down.

Alfred A. Wohlauer discussed the paper with regard to its application for certain measurements wherein the data given were at variance with the practice generally observed.

In his paper Mr. Hering defined the flux of light as representing the quantity of light radiation, as that which is bought, sold and used—that is, the statement of the amount of flux alone, without any further specifications, is not sufficient for industrial purposes.

Both Dr. Sharp and Dr. Hyde believed that the proper way to define flux would be as it was naturally used in practice, in terms of the quantity of luminous energy flowing across a surface of unit area per second; in other words, make specific flux a point function. Dr. Hyde did not believe that the spherical candle is the common unit of flux, and that we could not consider the official unit as a lumen.

E. L. Elliott said that the fact that so many authorities hold opposing ideas concerning the common unit to be used in the measurement of light was a sufficient evidence of the chaotic state in which photometric measurements still are. He could see no discrepancy in taking the spherical candle-power as the practical unit of flux of light. He believed that this term was understood by ninety-nine where there would not be one found who would know what the word "lumen" meant. As far as the hefner was concerned, it had the virtue of being established from an official source. If we traced the official candle which we call official in this country to its source, he supposed we would ultimately land in the Reichsanstalt in Germany.

In closing the discussion on this paper Dr. Hering said that he was simply taking things as they were. He agreed that as long as we use certain expressions to convey certain meanings, we should accept one term to mean one thing. If certain formulæ were not acceptable, they, of course, could be omitted. As far as the Geneva Congress was concerned, it was a matter of record that it was the first body to define the lumen, the lux and other units.

TUESDAY AFTERNOON SESSION.

The first paper taken up on Tuesday afternoon was entitled "The Calculation of Illumination by the Flux of Light Method," by J. R. Cravath and V. R. Lansingh. This paper was presented by Mr. Lansingh.

This paper described certain methods employed by the authors in calculating the illumination of large interiors, and showed the practical application to the suggestions made by Dr. Clayton H. Sharp in his presidential address before the first annual convention of the society, at Boston, July 30, 1907.

P. S. Millar called attention to the desirability of collecting and tabulating data bearing upon the coefficient of utilization of light. The ratio between the flux of light applied in a given installation and the values of the light generated, is a valuable factor. If we can determine that ratio in such a manner as to apply it in practice to rooms of various sizes, with decorations of various characteristics, we can readily work out complete illumination schemes before the installation is made.

The next paper was entitled "Street Lighting with Gas in Europe," by E. N. Wrightington. This paper was presented by R. C. Ware.

This paper described the types of burners which are being utilized for lighting Continental European cities. The inverted lamp seems to have been pretty thoroughly tested on the other side, and has given good results. The efficiency for useful light obtained greatly exceeds that of the upright lamp. There are two reasons for this advantage: first, because the proportion of light below the horizontal is much greater than from an upright mantle, and because the construction of the inverted-mantle burner permits the use of reflectors which will collect the upright rays and turn them in a useful direction. Most of these lamps are equipped with a pilot flame, and the main lamp is ignited by means of a lever arm. The most striking feature of street lighting on the other side is unquestionably the use of high-pressure inverted gas lamps. These lamps are found in very large units, running as high as 3,600 mean lower hemispherical candle-power. Posts are placed near together, and the streets are almost as bright as if lighted by daylight. The light is well diffused, and the effect very soft and pleasing.

Walton Forstall, in opening the discussion on this paper, asked whether there was any special pressure used with the intensified lights. He believed that at the gas exhibition in Dublin last year the pressure was sixty inches.

Dr. Bell replied to this question, to the effect that the sixty-inch pressure is the highest pressure that is being used with compressed gas. Compressed gas started a few years ago at ten or twelve inches; then it went to sixteen, and then to twenty, thirty and forty, and it has now reached sixty inches, which is the exact pressure of the system in Berlin. The distribution is through steel tubes, which are put together with gaskets. The lights are supplied by a tube-pressure pumping station operating gas engines. In Berlin the system uses compressed gas, and that seems to be the more usual tendency, although some of the systems use compressed air, and one system in Paris actually feeds oxygen obtained from liquid air to the burner to intensify the light.

T. J. Little, Jr., stated that he had recently experimented with seventy-one inches with a special mantle, with good results. He believed that this will revolutionize the whole business as far as high-pressure lighting goes.

Dr. Bell stated that to remove a possible misapprehension, it should be known that in the pressure gas burners the pressure is maintained to inspirate a sufficient quantity of air to give an intensified flame. There is in no case such a pressure of sixty inches against the mantle.

The paper entitled "Design of the Illumination of the New York City Carnegie Libraries" was read by L. B. Marks.

In this paper the author discusses the characteristics which are involved in the illumination of a public library. The layout of the various divisions is indicated, and the method adopted in providing just that illumination best suited for the service involved. The features of the design include: freedom from glare, all the lamps being shaded; the intrinsic brightness of the lighting sources is kept down to one-tenth of a candle-power per square inch; the general illumination is one foot-candle on the horizontal working plane; the horizontal illumination on reading tables is five foot-candles; the vertical illumination on the book shelves ranges from one and one-half to four foot-candles; the horizontal illumination on the book shelves ranges from four to eight foot-candles; the ceiling pendents for general illumination are designed for efficient use of tungsten lamps; lights near windows are placed on the same circuit as far as possible; the lamps for general illumination are hung high, but low enough to avoid sharp contrasts on the ceiling.

N. W. Gifford stated that the author gave five foot-candles as the proper amount of illumination on a reading table. He asked whether this was enough or too much; if there was not a popular tendency to ask for more light than was necessary. He said that in Boston the matter had been investigated by a commission, considering the question of school lighting. He believed the figure established was 2.5 foot-candles.

Dr. Bell replied that he was also of the impression that the figure was 2.5, but there seemed to be some doubt in the minds of the physicians as to what was the best figure for school-room illumination.

In closing the discussion Mr. Marks said that there is considerable question as regards the amount of illumination on the reading table. After an investigation covering six months in a New York public library, studying the conditions, the conclusion was reached that 2.5 foot-candles, under average working conditions, was not nearly enough for the readers who frequented the libraries. This is so to a certain extent because of the books being printed in different languages. With some of these the type is exceedingly small. What has been attempted in the installation described in the paper has been to establish a happy mean. A book can be placed in such a position as to get ten foot-candles on any reading table in the library. On the other hand, if the book is held just outside of the edge of the table, it will receive only 2.5 foot-candles.

The paper entitled "Engineering Problems in Illumination," by Alfred A. Wohlauer, was read.

The object of this paper was to present a conception of the duties of the illuminating engineer; to point out and to develop problems which have been solved by him, and to give an idea of the elements and fundamentals an illuminating engineer has to master in order to be able to carry out his work, and then lay down a clear and convincing proof that illuminating engineering is an individual profession.

Albert J. Marshall, in discussing Mr. Wohlauer's paper, called attention to the necessity for giving due consideration to both the utilitarian and æsthetic values in illuminating engineering work.

F. J. McGuire also called attention to the necessity for an illuminating engineer to consider æsthetic values, and not to assume too much importance with regard to the matter of economy of current. He called attention to several instances where the architects had opposed the idea of introducing the services of an illuminating engineer.

Mr. Lansingh directed attention to the fact that prismatic glassware had been developed which would enable the illuminating engineer to secure certain definite results that might be applied to areas of widely differing characteristics.

E. L. Elliott called attention to the large discrepancy which must always take place between theoretical and actual values. In attempting to obtain uniform illumination, for instance, in a store, where it would undoubtedly be desirable, in some cases it would be found in practice that after the engineer had secured, as nearly as could be calculated, a uniform illumination, there would be considerable variance after the lighting had been installed.

The paper entitled "Intrinsic Brightness of Lighting Sources," by J. E. Woodwell, was presented. An abstract of this paper is given elsewhere in this issue.

The discussion on this paper was opened by D. McFarlan Moore, who congratulated the society on taking up the subject of intrinsic brilliancy. He thought that Mr. Woodwell's statement that the intrinsic brightness rather than the distance of the source from the eye is the cause of the contraction of the pupil of the eye, is illustrated in exterior lighting in a remarkable way. He also stated that the theoretical specifications indicated in the paper are only met by the vacuum tube. In this system of lighting the illumination can be regulated over a large degree of brilliancy, but it is generated at the intensity a which it is used.

The paper entitled "Some Experiments on Reflection from Ceiling, Walls and Floor," by V. R. Lansingh and T. W. Rolph, was read.

The tests described in this paper were undertaken to determine the values of the reflection of light from ceiling, walls and floor under average conditions of artificial lighting. The paper described the test room, the lamps and reflectors, the instruments, and the methods of test. The conclusion is reached from these tests that the floor has little value as a reflector. Comparing the values with one lamp and reflector with those with three lamps and reflectors, the effective angle with light ceiling and dark walls and floor is sixty-three degrees in the first case and fifty-six in the second case. The average angle of sixty degrees may be considered as good for the assumed conditions with small rooms.

The paper entitled "Architecture and Illumination," by Emile G. Perrot, was read by the author.

Mr. Perrot holds that the architect's means of expression is by the use of materials of construction which must be so molded and shaped as to give the appearance of solidity; that is, that the building is a concrete reality; that it is solid and substantial in addition to being a thing of beauty. This effect is produced largely by means of shades and shadows. It is here that light plays a most important part in the bringing out of the details which characterize the work of the master architect. The study of the play of light and shade on the exterior of a building requires the highest kind of training for the successful outcome of an architectural composition. With interior lighting a different condition exists; hence the design of details for the interior of a building should not possess the same characteristics as are found on the exterior of buildings. His idea as to the way in which the Illuminating Engineering Society could materially help the architects would be by the publication of tables embodying standards and giving data and formulæ for the lighting of all types of buildings with various illuminants. If buildings are to be properly lighted and made to embody the latest improvements, the architect should be kept in touch with all that is new and desirable for the purpose of effectively and economically lighting the building he designs, with the view of wedding architecture and illumination. He believed this result could better be accomplished through the society than by any other means.

Following the discussion on this paper President Bell thanked the Philadelphia committee for the successful work which had been put into the convention. The total membership registered was 242, and there were visiting the convention 158. It had been especially gratifying to him as presiding officer to see the way in which the members had actually attended the business meetings. Wherever the next convention might be held, the local bodies would have to work hard to maintain the pace set by Philadelphia.

The meeting then stood adjourned.

Convention of the National Society for the Promotion of Industrial Education.

The second annual convention of the National Society for the Promotion of Industrial Education will be held at Atlanta, Ga., November 19, 20 and 21. The headquarters will be at the Piedmont Hotel, where the annual banquet will be held on Thursday evening, November 19. The meetings of the convention will be held at the State Capitol, House of Representatives. The exhibition of work by pupils of the trade schools will be arranged in the corridors of the State Capitol surrounding the House of Representatives.

The Fixation of Atmospheric Nitrogen.

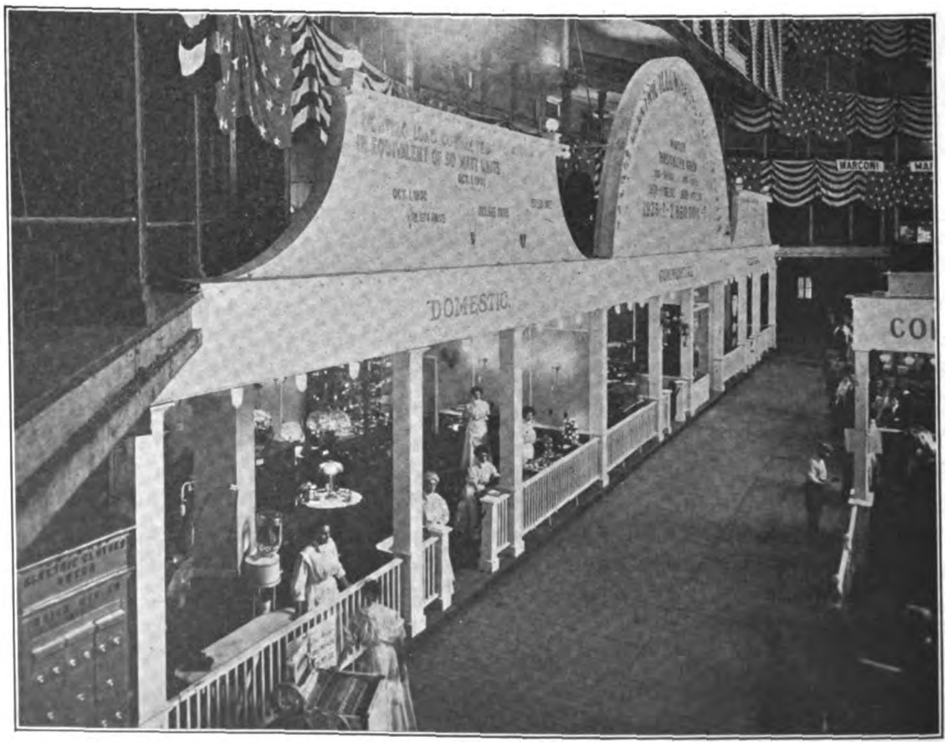
This subject was discussed at the recent International Congress of Applied Electricity, held at Marseilles, France. Mr. Blondin, vice-president of the section for Electrochemistry and Electrometallurgy, described the processes of Kowalski and Mocsicki and of Birkeland and Eyde. The latter process is characterized by the use of alternating-current arcs in the form of discs nearly two metres in diameter. The plant at Nottoden, in Norway, uses this process and consumes 36,000 kilowatts with an output of 500 kilogrammes of NO_3H per kilowatt per year. Mr. Blondin also described the Frank and Caro process used at Notre-Dame-de-Briancon for the manufacture of cyanamide of calcium. The fixation here is effected by the electric effluvium. The frequency used is fifty periods per second. It was stated that according to Birkeland the frequency is not of importance, as he had not obtained any improvement by increasing the periodicity. It would seem that the ionizing action has very little influence, perhaps one in 1,000. Reference was likewise made to the process of Professors Gorbow and Mitkievitch, of St. Petersburg, who employ a high-tension three-phase current with furnaces consuming a maximum of fourteen kilowatts for producing nitrous oxide. The results show a production of 480 kilogrammes per kilowatt-year. The process is not yet applied on an industrial scale. The Pawling process used at Innsbruck was next brought to the attention of the congress. It is based on the system of horn lightning arresters, furnaces of 500 to 700 kilowatts being used, and is characterized by the direct production of thirty-six to forty-degrees Beaumé nitric acid. Researches made by Professor Haber, of Karlsruhe, were also mentioned. He has found that the principle of increasing the output lies in improving the ionizing action of the arc. In order to do this a lowering of the temperature is indispensable, a high temperature being one of the great obstacles to the ionizing influence. Professor Haber has realized the necessary condition by slightly decreasing the pressure and utilizing electrodes of Nernst material. The ionizing action undoubtedly takes place, as a thermic calculation will indicate. The concentration of the oxide, which is five per cent in the Birkeland process, amounted to fourteen per cent in the Haber experiments.—*L'Industrie Electrique (Paris), September 25.*

Photographs of the New York Electrical Show.

The accompanying illustrations are interesting as showing the extent to which decorative features were carried and actual demonstration of material made at the New York Electrical Show, which was held at Madison Square Garden recently.

One of the most prominent features of the show was the huge "Brooklyn" sign, spanning the Fourth avenue end of the amphitheatre. The Brooklyn Edison exhibit presented a unique exemplification of the utility of electrical devices and was divided into representations of domestic, commercial and industrial applications. The façade overtopping the booth was made to illustrate the great growth of the Brooklyn Edison system during the last decade.

THE BROOKLYN EDISON SIGN AT THE NEW YORK ELECTRICAL SHOW.



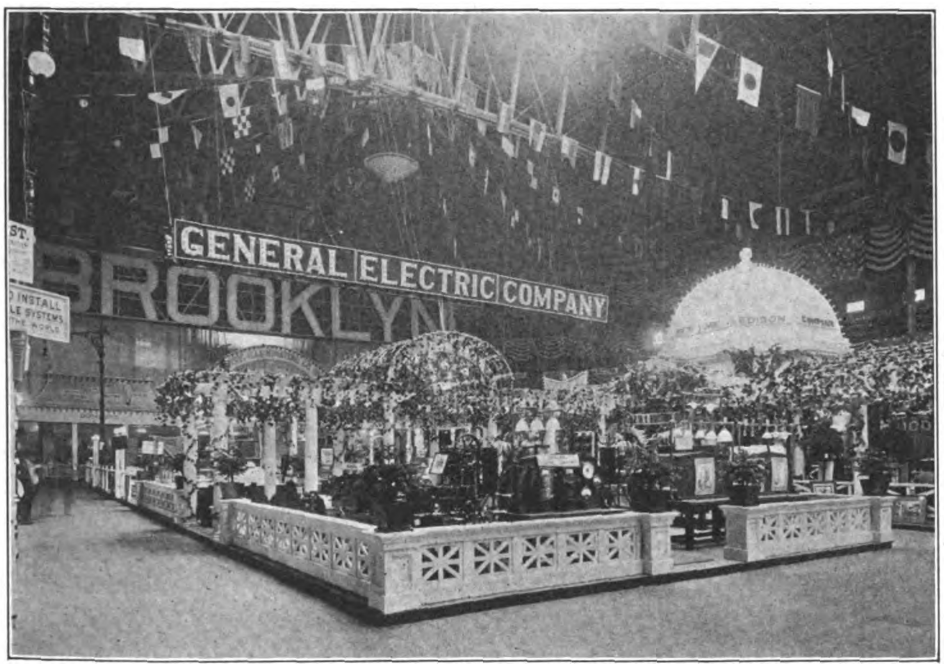
THE BROOKLYN EDISON EXHIBIT AT THE NEW YORK ELECTRICAL SHOW.

Other illustrations show the booth of the General Electric Company, which had one of the most artistic exhibits in the hall. Tungsten and tantalum lamps were the features of this exhibit as well as the principal objects of interest of the entire show. The large space occupied by the company was divided down the centre by a brick-floored pergola covered with vines and illuminated by forty, sixty and 100-watt tungsten lamps in Holophane reflectors. The effective beautiful green and white of the pergola in the brilliant rays of the tungsten lamps was further enhanced by miniature bulbs sparkling in the foliage. On one side of the pergola the company exhibited its complete line of electric heating devices, including the new electric toaster, a valuable adjunct to the electric chafing-dish, the new continuous heat of cigar lighter, and special kitchen outfits and ovens. At this end of the space a comparison was shown of the tungsten and carbon-lamp efficiency by means of the lamp-testing watt-indicators, and the new twenty-five-watt tungsten lamp was exhibited for the first time.

On the other side of the pergola tables were arranged with brass arches for showing the complete line of tungsten and tantalum lamps, and the new high-efficiency merging-prism Holophanes. A Deshler-McAllister photometer was arranged with a forty-watt tungsten lamp and a thirty-two-candle-power carbon lamp giving practically the same candle-power, and attached to two Thompson induction wattmeters with special rapidly-moving dial trains, so that the different rates of current consumption with equal candle-power were strikingly exhibited. This part of the booth was of particular interest to central station managers and supply dealers who appreciated the suggestion for a window display.

In the centre of the aisle was a direct comparison of one 250-watt tungsten lamp and thirteen sixteen-candle-power carbon lamps giving approximately the same candle-power, with a comparison of relative cost of current consumption per month. The two types of lamps were suspended from opposite ends of a balance arm, and on an arch above were three 250-watt tungstens in Holophane shades, which were exhibited as having approximately the same current consumption as the thirteen sixteen-candle-power carbon lamps below.

One of the most interesting features of the exhibit was a case of miniature tungsten lamps showing the innumerable forms in which it has been perfected by the General Electric Company. There were types suitable for use on automobiles, motor boats, table lamps, vest-pocket lights and practically all forms of low-volt and battery-service lamps were included in the many samples shown. The case was illuminated by fifteen-volt tungsten series sign lamps of four candle-power each.



The General Electric Company at the New York Electrical Show.

The General Electric Company also loaned the exhibition company a quantity of tungsten lamps for use in the chandeliers of the Madison Square Garden, this being the first time that the Garden has been so illuminated.

A 6,000-ampere direct-current wattmeter was the head of a line of instruments which extended to the new Type L portable lamp-testing watt indicator, which can be screwed into an ordinary socket and indicates the different watt consumptions of single incandescent lamps. Standard switchboard panels, generator panels, moving-picture machines, mercury arc rectifier panels, automatic compensator panels for alternating-current motors, and miscellaneous rheostats, circuit-breakers, contactors, etc., were displayed to advantage, as well as a small thirty-two-kilowatt Curtis steam-turbine generator set. Two new fifty-hour flaming arc lamps added to the blaze of illuminations surrounding the booth.

The representatives of the company included F. H. Gale, J. O. Case, W. J. Canning, T. Beran, C. E. Estabrook, A. D. Babsom, W. S. Brayton, F. C. Bates, A. D. Page, F. W. Willcox, G. C. Osborn, R. B. Parker, Henry Schroeder and W. C. Andrews, and a large number of visitors from the engineering and sales departments of the Schenectady works, among whom were seen M. P. Rice, C. W. Stone, W. S. Andrews, C. W. Bartlett, F. H. Vaughen, E. M. Hewlett, W. J. Newcomb and W. P. Brown.

The illuminating engineering department of the General Electric Company was represented by W. D'A. Ryan and G. H. Stickney, who used a pair of tungsten diffusers suspended in the pergola and the exhibit of tungsten lamps as texts for many instructive lectures on the new problems being solved in the lighting art.

Light and Power Plant for Twillingate, Newfoundland.

Boston capital has become interested in modernizing the city of Twillingate, Newfoundland, and as the initial and basic step will establish a plant for electric light and power. This will be the third such plant in Newfoundland, and basing opinion on the experience of those already in action, the enterprise is destined to be an exceedingly profitable one for those interested.

The city has a population of above 11,000, within a radius of four miles, and the plant will start with about 6,000 lights, including 500 street lights. The charter of the Twillingate company is direct from the government and covers the entire district, which embraces an area of about forty miles and contains a population of over 72,000.

The plant will consist of two 250-kilowatt steam turbines, it not being considered wise to depend upon the water power at hand. Based upon present contracts the Twillingate company shows a net profit the first year of seventeen per cent on its capital.

The plant is being installed under the supervision of Frederick S. Palmer, 103 Bedford street, Boston, Mass., who is president of the company and who has associated with him several Boston and Newfoundland financiers.

REVIEWS OF CURRENT ENGINEERING AND SCIENTIFIC LITERATURE

Electrification of the Melbourne Suburban System.

The Victorian Railway Commissioners, who are responsible for the management of the state railways of Australia, have, for some time past, been considering the advisability of applying electric traction to the Melbourne suburban lines, which form the most important part of the whole railway system. The number of suburban trains in Melbourne forms only 4.5 per cent of the total, while the suburban train mileage forms forty per cent of the total train mileage of the system. The suburban system has some 240 miles of track and 126 stations. For the year ended June 30, 1906, the suburban system had a train mileage of 2,772,669 miles, with 4,080,135 train-miles for the remaining system. The Melbourne suburban railway system is one of the most important in the world, and as the service given at the present time by steam locomotives is very good, the question of changing it requires careful consideration. Charles Merz, consulting engineer to the railway commissioners, has presented an exhaustive report, going into the whole question in great detail. Mr. Merz suggests that the possibility of increased schedule speed is the characteristic feature of electrical operation with a suburban service. To obtain this increased schedule speed, higher acceleration is required. The acceleration at present with steam operation in Melbourne is 0.36 mile per hour per second. By increasing the acceleration to 0.9 mile per hour per second, the time taken for an average run of 0.825 of a mile can be reduced from 147 seconds to 118 seconds. To do this with steam locomotives would not pay, whereas it is easy to obtain a considerably higher acceleration with electric traction. Mr. Merz recommends that normally electric trains should consist of an equal number of motor and trailer coaches. The trains would thus consist of two, four and six coaches, as may be required. For various reasons the three-phase system of operation is not recommended, and it practically comes down to a choice between single-phase system with overhead wires and direct-current system with a protected conductor rail. Further calculations show that the protected conductor-rail system at about 800 volts has many advantages over an unprotected third-rail system at a lower voltage. The adoption of the single-phase system for suburban service has in the past been influenced by the possibility of extending it in the future to long-distance branches. In the case of Melbourne the importance of the suburban traffic preponderates so much that this factor does not enter into account, for the main lines are such that is is doubtful if they will ever need electrifying. After working out in detail the cost of handling the Melbourne traffic with both systems, Mr. Merz finds that the additional cost of the train equipment with the single-phase system would practically balance the extra expenditure on the substations required in the case of the direct-current system. When the annual cost is considered it is found that under the Melbourne conditions the direct-current system shows a saving compared with the single-phase system, so that the latter can not be recommended on financial grounds. The generation and supplying of the necessary power will involve the production of 68,000,000 Board of Trade units per annum, a maximum load of 32,000 to 35,000 horse-power, and an annual expenditure of $500,000.—*Abstracted from Engineering (London), September 25.*

The Trackless Trolley System.

A deputation appointed last July by the Manchester Corporation Tramways Committee, of Manchester, England, to inspect the trackless trolley systems in operation in certain towns in Germany, has presented its report. Among other considerations, it is pointed out how the cost of operating tramways may be divided into running expenses, which remain approximately constant no matter how the total car mileage increases; and standing expenses, which decrease as the number of car-miles per mile of track increases. In illustration of this a table is worked out to show how such expenses increase per car-mile as the number of car-miles per mile of track increases. Taking extreme cases, it is seen that with a figure of $1,900 per mile of single track, with a half-minute service the standing expenses are 0.276 cent per car-mile only; whereas with half-hour service they reach the sum of 16.52 cents. Taking the receipts at twenty-two cents per car-mile, and the running expenses at seventeen cents—that is, the surplus receipts at five cents per car-mile—it would appear from the table that a nine-minute service is the economic limit. The report considers briefly the advantages of tramways for city traffic over mechanically propelled vehicles running independent of rails and independent of a central power station. It is pointed out that the work which a tramcar has to do varies considerably at different periods of the year. In winter, when the track is in bad condition, the tractive effort required reaches its highest point, but this may occur only for a few weeks. It is better and more economical to generate energy to provide for these peak loads in large quantities in a central power station than to provide each separate vehicle with an equipment for generating or for storing its own energy, which may only be called upon for its maximum output a few times a year, but which will have to be carried about by the cars all the year round. The only field for the motor bus is in towns or cities where tramways are not permitted or in suburban districts where the traffic is not sufficiently great to warrant the laying down of tramway rails; and in the latter districts it will have a competitor in the trackless trolley. For providing means of transit beyond the economic tramway limit the trackless trolley system claims consideration. The report describes the three trackless trolley systems inspected by the deputation in Germany. One connects the townships of Monnheim and Langenfeld, near Cologne, and was opened for traffic in 1904, and is two and one-half miles long. The overhead equipment is of the bracket-arm type, and there are two trolley wires. The passenger car is a single-deck vehicle equipped with a twenty-five-horse-power motor, with a front-axle drive by ordinary gear wheels. The car carries thirty passengers. Another line connects the townships of Neuenahr, Ahrweiler and Walsporzheim. This was opened in 1906, and is a little over three miles long. The cars weigh three tons two hundredweight, seating twenty persons. They are driven from the front axle by a twenty-horse-power motor. The front wheels are rubber-tired, and the back ones are steel-tired. The town of Mulhausen is equipped with the most up-to-date system of trackless trolley. The overhead equipment consists of four trolley lines—two positives and two negatives. This does away with the necessity, when cars are passing, for one of them pulling off the trolley, or eliminates special passing places. The cars weigh fifty hundredweight, and are equipped with one trolley boom, as against the two trolley booms with which the other systems are furnished. The deputation considers that the system, as seen by it in Germany, will require some modification to satisfactorily fulfil English conditions. In reviewing the financial aspect of the matter and making comparison with petrol omnibuses, it is remarked that trackless trolleys would be cheaper to operate than internal-combustion motors. As regards reliability, the report concludes that the commission would have more faith in cars equipped with tramcar motors satisfactorily fulfiling requirements, than in cars equipped with internal-combustion or steam engines as developed at this time. Aesthetic advantages are also pointed out. The corporation, it is understood, will present a bill to the next session of Parliament, asking for powers necessary for equipping and operating a trackless trolley system. In the meantime further observation will be made of the type of car and car equipment best suited to the English requirements.—*Abstracted from Electrical Engineering (London), October* 1.

The St. Clair Tunnel Electrification.

Increase in capacity was the primary object of the electrification of the St. Clair tunnel. Steam locomotives could scarcely clear the summit of the grade leading out of the tunnel with a 700-ton train. The single-phase electric locomotives with which this system is now equipped can take a 1,000-ton train up the two per cent grade at ten miles per hour. The locomotives have also solved the tunnel ventilation problem and removed a serious handicap to the passenger service. They have also made the service better in other respects. For instance, air brakes can now be used on freight trains in the tunnel. Under steam conditions the use of air brakes on freight trains was such a dangerous matter that hand brakes only were used, except on the locomotive. The use of air brakes meant that when a train broke in two on the grade in the tunnel, a portion of the train oscillated back and forth several times before it could be brought to rest with the hand brakes. The danger from the air brakes was due to the fact that the time required to recouple the train and release the brakes exceeded the time the steam locomotive could be kept in the tunnel with safety. The electrification has solved the problem of heavy service, heavy grades and bad ventilation. At Port Huron, the St. Clair River is very deep. The level portion of the tunnel is 100 feet below the level of the yards. The distance from the summit to summit is approximately two and one-quarter miles. Approximately a half mile at each approach is an open cut. The power station is situated on the Port Huron bank of the St. Clair River, at a point almost directly over the tunnel. The building is of concrete construction to the dynamo room floor. The walls above this point are lined with paving block and are corniced and coped with concrete. The roof is of cinder concrete. The walls are lined with enameled brick to the height of the switchboard. The remaining portion is lined with sand lime brick. The offices and switchboard room occupy the street front. The basement has plenty of head room and contains the condenser pump groups and stoker fan groups. The dynamo room floor is so recessed that the auxiliary apparatus in the basement is in view from the dynamo room floor. The boiler room floor is on the same level as the dynamo room basement floor. The power-station equipment is in duplicate, and there are two 1,250-kilowatt, three-phase, twenty-five-cycle, 3,000-volt turbo-generators. Either of these is capable of handling the maximum demand upon the station. The turbines have a large overload capacity, and the boilers have extra large steam drum capacity. The four boilers have a nominal rating of 400 horse-power each, and each boiler has three steam drums. Just outside the power station there is a vertical shaft which extends to the tunnel. A reinforced concrete duct chimney has been built in this shaft as a continuation of the power station duct lines. All the feeders pass from this chimney through holes in the tunnel shell into the tunnel. The locomotive feeders tap the trolley and rail at this point, which is the only distributing point for the entire trolley system. In addition to the locomotive feeders there are two feeders for the tunnel lights, two feeders for the Port Huron portal pump groups, two for the Sarnia portal pump groups, a three-phase power feeder and an arc-light feeder for the Port Huron yards, and similar feeders for the Sarnia yards. These cables are carried through the tunnel in ducts which are supported by reinforced concrete beams and secured to the lining of the tunnel shell. In the yards a single catenary trolley construction is used, while in the tunnel a modification of the catenary construction is employed. There are two parallel messenger cables and two parallel trolley wires. The messenger cables are supported on barrel-shaped insulators spaced at intervals of twelve feet. These messenger cables carry special double trolley hangers, which are also spaced at intervals of twelve feet, but located three feet from the middle of the messenger span. The tunnel is damp throughout a considerable portion of its length, but although the 3,300-volt bare wires are carried within three inches of the cast-iron shell, but two insulators have failed since the electric locomotives were put in operation. The tunnel division is protected by a block signal system which extends from summit to summit. The dispatcher's cabin is located at the Sarnia summit, and the other signal cabin at the Port Huron summit. Telegraph orders are used. In addition to the written order the conductor receives a staff when the train enters the block. The switches and signals are locked until this staff is placed in the instrument at the other end of the block.—*Abstracted from the Electric Journal (Pittsburg), October.*

The Kansas Gas, Water, Electric Light and Street Railway Association.

The eleventh annual meeting of the Kansas Gas, Water, Electric Light and Street Railway Association was held in Pittsburgh, Kas., October 8 and 9.

President C. L. Brown, of Abilene, called the meeting to order at 10 A. M., October 8.

The first order of business was the appointment of the following committees: Nominating Committee—R. C. Johnston, T. J. Huntington and W. E. Sweezey; Resolutions—B. F. Eyer, C. M. Lewis; Time and Place of Meeting—H. A. Almert, W. A. Scothorn; Auditing Committee—J. E. Taylor, W. F. O'Connor.

Officers for the coming year were elected as follows: President, W. A. Scothorn, Hutchinson; secretary and treasurer, James D. Nicholson, Newton.

Wichita was selected as the next place of meeting.

Twenty-one new members were elected and the meeting was the best ever held by the association in point of attendance, programme and entertainment. The theatre party, trolley ride and banquet were well attended and heartily appreciated.

INDUSTRIAL SECTION

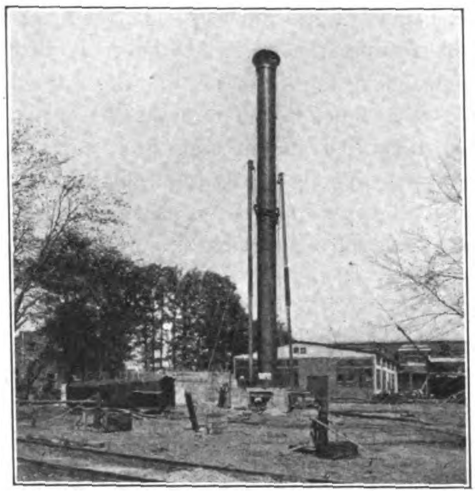
ILLUSTRATED DESCRIPTIONS OF NEW AND STANDARD ELECTRICAL AND MECHANICAL APPARATUS

Big Boiler Stack Erected at Ampere.

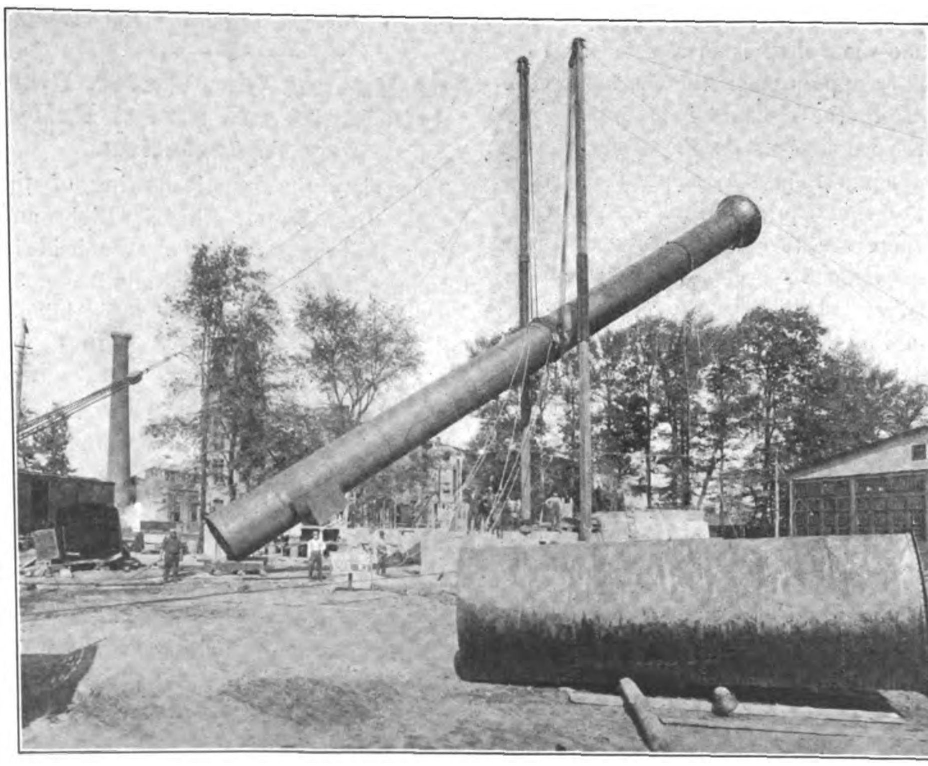
The improvements to the plant of the Crocker-Wheeler Company, of Ampere, N. J., manufacturer of electrical machinery, have reached the stage where work is being started on the new power-house, which when completed will have a capacity of 4,800 boiler horse-power. This entire capacity will not be installed at once. To furnish draft for the boilers temporarily, until the complete plant is installed, the company has erected a steel stack, seventy-two inches in diameter and 105 feet high, standing 125 feet in the air.

This stack will supply natural draft to 800-horse-power water-tube boilers (burning No. 2 buckwheat coal), with an ultimate capacity under artificial draft of 1,600 horse-power. The boilers are of the modern high-pressure water-tube type (steel castings) for generating steam at 200 pounds pressure. The furnaces of the boilers are each nine feet eight inches wide by ten feet deep. The breeching connection between the stack and the boilers is six feet wide, and increases in height as it reaches the stack to provide for future installation of boilers.

The breeching is built of the arched-top and bottom-plate construction to make it self-supporting. The weight of the stack and breeching is approximately eighteen to twenty tons and the stack was hoisted into position in one piece, which attests the progress of engineering construction, as this would have been impossible a few years ago. The present stack is to be used temporarily until the further development of the plant, at which time it is contemplated to erect permanent brick chimneys. For that reason the stack is located at present in position to provide for future development until the last boiler installation is made, and is erected on one of the future boiler-setting foundations. This foundation is built of concrete and that portion on which the base of the stack rests is reinforced with steel. The stack connection to the foundation is provided by means of a cast-iron sectional annular ring which is bolted to the foundation and also to the stack.



THE NEW STACK IN POSITION.



HOISTING THE NEW STACK INTO POSITION AT THE GROUNDS OF THE CROCKER-WHEELER COMPANY AT AMPERE, N. J.

The stack was designed and erected by the engineering-construction office of Walter Kidde, New York city. It was built by the Dover Boiler Works, of Dover, N. J.

New Type Circuit-Breaker.

Both fuses and circuit-breakers are recommended by the fire insurance underwriters for use with motors because in the smaller installations the circuit breakers are too expensive. For this reason fuses are often used, even though the work of replacing them when blown is excessive. Fuses are in many cases dangerous as well as expensive and troublesome to maintain. It is not an infrequent sight to find a blown-out fuse replaced by so heavy a wire that it could burn out only with a current which would severely damage the apparatus it is supposed to protect.

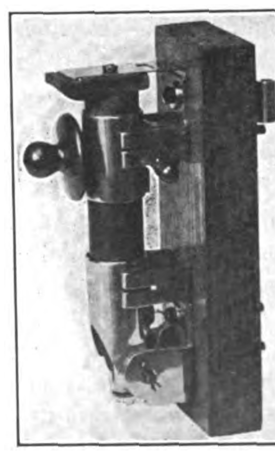


FIG. 1.—CIRCUIT-BREAKER CLOSED.

The general use of circuit-breakers has been limited because of the first cost of the installation. In order to provide a breaker which shall be able to compare in price with enclosed fuses, the Westinghouse Electric and Manufacturing Company has developed a small carbon break-circuit-breaker known as the Type F.

The illustrations show the compact and neat construction of the circuit-breaker, suggesting the appearance of a cartridge fuse. The tripping device is inside the movable arm; it may also be tripped by hand by the small insulating handle shown in Fig. 1. In addition, an auxiliary magnet coil may be attached to provide for tripping the switch from a distance, such as is required in connection with automatic limit switches on machine tools.

These circuit-breakers are made in four sizes for twelve and one-half, twenty-five, and fifty and seventy-five amperes. Each has an operating range of from eighty to one hundred and sixty per cent, that is, the tripping device may be set for any current within these percents of the rated capacity. Adjustment is made by a knurled nut at the lower end of the arm and may just be seen in Fig. 1. These breakers are made in single-pole types for direct current up to 250 volts and alternating current up to 440 volts, and are approved by the National Board of Fire Underwriters.

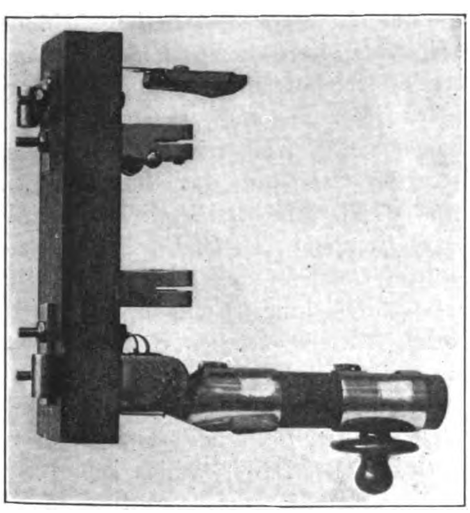

FIG. 2.—CIRCUIT-BREAKER CLOSED.

The standard circuit-breaker is mounted on a porcelain base, similar to the mounting of a fuse, with all the connections on the face of the porcelain to permit being placed directly on the wall. However, it is also supplied for switchboard and control tablet work where the connections are made on the back; two screws are provided for mounting under these conditions. The outfit as a whole takes up practically no more space than an enclosed fuse of the same capacity.

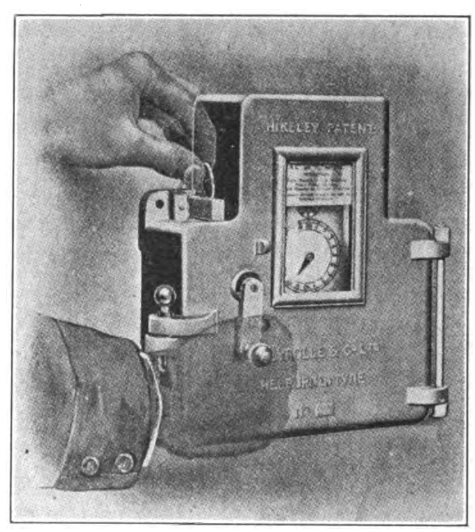
An English Prepayment Electricity Meter.

A method of charging in small installations, where the cost of an ordinary meter is not justified, is coming into use in some places, where the charge is based on the number of hours' use of current, irrespective of the number of lamps that are being fed. This system has met with considerable favor in some parts of Spain, says *Electrical Engineering*, London, and has lately been developed in England in a tentative manner on the mains of the large supply companies in the Northumberland and Durham areas.

It is therefore of interest to give a few details concerning the Hikeley patent meter, which has been especially designed to meet these requirements for installation up to about eight lamps. Briefly, the meter is supplied for use with alternating or direct currents, and is of the prepayment type. The circuit is closed automatically by putting one or more pennies in the slot, and the switches remain closed for a period depending on the number of coins inserted. The standard design is such that for every penny current can be used for five and one-half hours, but the calibration can be altered to suit any other rate.

The general appearance of the meter is shown in the illustration. It consists essentially of a clock with an electrically operated detent, beyond which there is no electrical metering gear about it. The clock operates a large toothed disc seen inside the instrument, tending continually to turn in one direction. If this motion goes on uninterruptedly it will, at the end of the travel, operate a trigger which, on being knocked away, allows the switch on the meter to open. The act of putting in a penny and moving a handle in accordance with the directions given, virtually "puts back the hands of the clock," and gives the tenant a further period before the trigger is operated. The motion is effected by first bringing the outside handle, which engages with a drum slotted to receive the penny, to the upward limit of its path. The penny, on being inserted, acts on a connecting piece between this drum and a toothed wheel, controlled by a spring and engaging with the large toothed disc. On bringing down the outside handle the large disc is thus turned through a position equal to one pennyworth, the penny is then dropped into a cash box, and the small toothed wheel is released from the drum. The position of the pointer on the front dial then shows the number of hours' running which the consumer has in hand before further payment becomes necessary. The slot in the drum is made large enough to allow a halfpenny to fall clear, so that if anyone attempts to defraud the electricity supply, the biter becomes bit.

As in slot machines of all descriptions damage is continually done by the insertion of bent pennies, the opening for the admission of coin just allows a straight full-sized penny to pass. The gauge has, however, a slight upward movement, so that, should a bent penny be inserted and stick, it can be lifted slightly and the penny prized from below. The cash box is sealed separately from the cover of the case, so the man who periodically winds up the clock can not collect the money without breaking the seal. With regard to winding, this in practice is found to be necessary about once a month, as the clock provided runs continuously for a fortnight, and the electrical detent prevents it from working when no current is passing.



THE HIKELEY PREPAYMENT WATTMETER.

The current passes through the winding of the electromagnet, which only allows the clock to run while current passes through it. A current equivalent to one eight-candle-power lamp is sufficient for it to operate the detent. The current then passes to one contact of a double switch, with entirely separate arms, through these two switch arms in series to the terminal block of the meter. It is purely in series on one limb of the lighting circuit, no shunt connection being used. The object of the double-arm switch is to prevent fraud. One obvious way to close the switch of the meter would be for the action of the handle, either upward or on its return journey, to bring the brush down into a contact, but this would allow a dishonest person to tie the handle in position without placing a penny in the slot. The way in which this is overcome is to have two separate bridge arms, one closed by the upward sweep of the handle, and the other by its return stroke. Moreover, unless the insertion of a penny has in the meantime caused the disc with the tripping device to be rotated, the trip will immediately operate on the downward stroke of the handle, and no current can be obtained. If there is no money "banked" in the machine in the form of hours to run, the back switch will not operate, but it should be noted that the handle of the meter can, if necessary, be used as a main switch, as the operation of the handle without the use of a penny will not move the pointer either backward or forward.

In the illustration it will be noted that the top portion of the window is occupied by a tablet giving instructions as to the working of the meter. The front of the case is hinged and padlocked; if it is swung back there will be seen a set of check dials covered from the consumer's observation by the instruction label, showing the total number of hours that the meter has been working. By comparing the hours run by the money in the cash box the collector can immediately detect theft of money. The electromagnetic detent which holds the balance in such a position that the clock will start again when the detent is withdrawn, can be reached for examination from the back of the meter, which, on being screwed to the meter board, is inaccessible to the consumer. The detent is of peculiar construction, consisting of a thin reed so arranged that, while it yields very easily to the pin on the balance wheel in one direction, it becomes rigid and detains the pin on the return stroke. The detent is withdrawn smoothly on the action of the electromagnet.

The whole design appears to be of strong and substantial construction, and the over-all dimensions of the device are about nine inches by eight and one-half inches, by five and one-half inches. A. Reyrolle & Company have developed Mr. Hikeley's patent, and the device has now been in successful use for about two years.

Electrical Supplies for the Navy Department.

The Bureau of Supplies and Accounts will open bids in Washington, D. C., on November 17, for a large quantity of electrical material for delivery at various yards, under schedule No. 471.

Machine-Tool Controllers.

The self-contained drum-type machine-tool controller illustrated herewith is a recent addition to the line of electric-controlling devices designed for use with motor-operated machine tools.

It possesses the advantage of combining in one compact piece of apparatus the speed-regulating mechanism and the resistance.

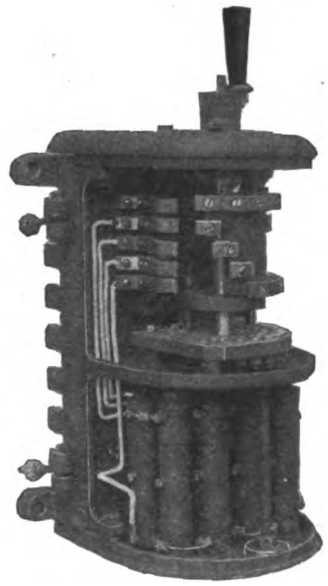


Fig. 1.—Front View of Machine-Tool Controller.

Fig. 1 is a front view of this new type of controller and shows the removable resistance units mounted in the lower half of the controller with insulated wires running from each unit to the metal "fingers" in the upper part of the device. These units constitute the armature resistance and are employed for starting duty only.

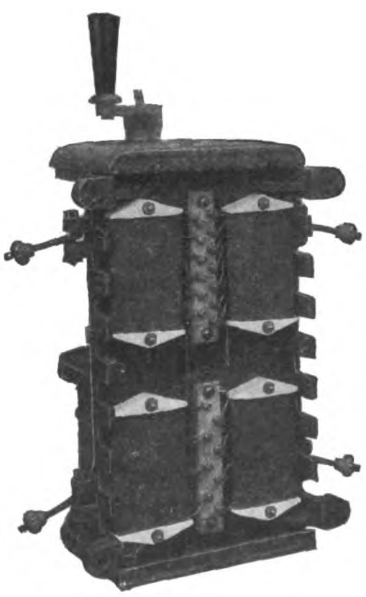

Fig. 2.—Rear View of Machine-Tool Controller.

Fig. 2 is a rear view of the same drum and shows another type of resistance unit —also removable—mounted on the back of the controller. The four units shown in this view constitute the field-regulating resistance and are divided into twenty steps, providing a range of speed variation of 2 to 1 or 3 to 1.

These controllers are made for both reversible and non-reversible motors ranging from one to seven and one-half horsepower, and are designed for use on either 100 or 220-volt direct-current circuits. They are made by the Cutler-Hammer Manufacturing Company, of Milwaukee.

Electrical Manufacturers at the Street Railway Conventions.

The annual exhibit of the American Street and Interurban Railway Manufacturers' Association, held in conjunction with the conventions, the proceedings of which are reported on other pages of this issue, covered the entire expanse of Young's Million-Dollar Pier, Atlantic City, N. J. At the annual meeting of the Manufacturers' Association, held on Wednesday afternoon, the following members of the executive committee were elected: For the one-year term: K. D. Hequembourg, Walker & Bennett Manufacturing Company; for the three-year term, J. R. Ellicott, Westinghouse Air Brake Company; C. C. Castle, Hildreth Varnish Company; J. H. McGraw, McGraw Publishing Company; W. K. Porter, Electric Service Supplies Company; Cornell S. Hawley, Consolidated Car Heating Company.

The *Electric Railway Journal* published a "Convention Daily," which kept everyone in touch with the proceedings of the various organizations, and formed a complete reference to the exhibits of the manufacturers.

There were nearly two hundred exhibitors of every appliance appertaining to electric railway service, outside of the track exhibits, adjacent to the pier. Among these may be mentioned:

LIST OF EXHIBITS.

The Allis-Chalmers Company, Milwaukee, Wis., showed an operating exhibit of air-brakes and parts, steam turbine parts, pictorial exhibit of other products. Represented by F. C. Randall, J. F. Dixon, H. W. Rowley, Harry Byrne, A. P. Peck, W. G. Clayton, J. T. Cunningham, St. John Chilton, J. B. Nicholson, S. H. Payne, J. M. C. Lucas, A. H. Whiteside, J. R. Jeffrey, J. H. Denton, W. A. Crawford, I. L. Dimm, W. S. Heger.

The American Steel & Wire Company, Chicago, Ill., exhibited bare and insulated wires and cables, rail bonds and rail bond tools, springs, wire rope and strand, woven wire fence, concrete reinforcement. Represented by F. Baackes, C. S. Knight, Jr., G.

A. Cragin, F. A. Keyes, C. R. Sturdevant, R. K. Sheppard, J. D. Sutherland, A. G. Greenberg, R. H. Pratt, B. H. Ryder, G. C. Kiefer, L. A. Dietrich, E. W. Vaughan, Chas. Larson, B. B. Ayers.

The Alfred and J. M. Anderson Manufacturing Company, Boston, Mass., showed its new remote-control oil switch, new brushholders for heavy railway service, third-rail insulators, Aetna railway insulators and Anderson line materials, new strain insulator of drop-forged steel. Represented by J. M. Anderson, Alfred Anderson, W. W. Hincher, G. C. Crane, Ernst Woltman.

The Blake Signal & Manufacturing Company, Boston, Mass., exhibited Blake despatcher's signals, Blake tube soldering flux, Blake wiring specialties. Represented by E. J. Burke, C. C. Blake.

The Buckeye Engine Company, Salem, Ohio, made its usual exhibit of photographs of steam and gas engines. Represented by C. H. Weeks, A. H. Riddell, James T. Castle.

The Chicago Pneumatic Tool Company, Chicago, Ill., showed a complete line of electric drills, hoists and grinders, spike-driving electric drill, air-compressor, air tools, vacuum cleaners. Represented by W. O. Duntley, Thomas Aldcorn, G. A. Barden, F. C. Severin, W. F. Heacock, Charles Booth, W. P. Pressinger, H. B. Griner, C. B. Coates, Howard Small.

The Consolidated Car Heating Company, Albany, N. Y., exhibited its well-known electric heaters and switches, trolley voltage signal bell system and crossing signal. Represented by Cornell S. Hawley, W. S. Hammond, J. Thomas Farmer, Jr., George H. Diack.

The Crouse-Hinds Company, Syracuse, N. Y., showed its arc headlights, incandescent headlights, mine headlights. Represented by H. B. Crouse, A. F. Hills, F. M. Hawkins, C. M. Crofoot, F. Buchanan, D. C. Gidley.

The D. & W. Fuse Company, Providence, R. I., exhibited enclosed fuses and cutouts of all types for 250, 600 and 2,500-volt circuits, service switch boxes, fuse boxes, cutout boxes for railway lighting and motor service, railway shoe fuse boxes, transformer and high-tension cutouts, and Deltabeston magnet wire. Represented by W. S. Sisson.

The Joseph Dixon Crucible Company, Jersey City, N. J., had on exhibition a special steel building and made a display of Dixon's Ticonderoga flake graphite oil, lubricants, silica graphite paint. Represented by DeWitt C. Smith, L. H. Snyder, J. A. Condit, John J. Tucker, Thos. Findlay.

Dossert & Company, Inc., New York, N. Y., exhibited solderless cable connectors. Represented by H. B. Logan, C. A. Flynn, D. J. Fitch.

The Electric Service Supplies Company, Philadelphia, Pa., exhibited its new "Pay-Within" car, "Protected" rail bonds, Keystone overhead line material, Garton-Daniels lightning arresters, automotoneers, Lyon sheet steel gear cases, Keystone air sander trap, Keystone pneumatic bell ringer, Keystone lamp guard, pneumatic door operating mechanism, compressed air door operating mechanism. Represented by C. J. Mayer, J. W. Porter, J. V. E. Titus, A. H. Englund, M. A. Berg, E. R. Mason, F. H. Jameson, H. G. Lewis, Edw. Hammett, H. R. Swartley, Jr., W. A. Armstrong, Jr., T. F. McKenna, F. A. Strail, R. P. H. Staub, F. C. Peck.

The Electric Storage Battery Company, Philadelphia, Pa., exhibited several styles of samples of the "Chloride" accumulator, diagrams of the new split-pole rotary converter, used for regulation of alternating-current loads, curves showing the regulation, and an average adjuster. Represented by Charles Blizzard, J. L. Woodbridge, G. H. Atkin, Albert Taylor, H. B. Gay, Edward L. Reynolds.

General Electric Company, Schenectady, N. Y., showed its type M automatic control for four seventy-five-horse-power motors, US-13 trolley base with twelve-foot trolley pole and Form 21 fork with wheel, trolley forks and wheels for various speeds, MR12 circuit-breaker, MS-8 switch, K-35, K-36, K-34 controllers with handles, fuse boxes, contactors, switchboard panel for Type M control, car light regulator, emergency straight air-brake equipment with compressor for motor car, emergency straight air-brake equipment for trailer car mounted on rack for operation, motorman's valves, emergency valve, governor, split, solid and forged rim gears, cast-steel center for gears, armature and field coils commutator segments, armature linings for GE-216 motor, Grade F pinion, section of field coil showing effect of vacuum compound treatment, 600 1200-volt railway motor, rail bonds, catenary and standard direct suspension line material, electrolytic car lighting arresters, Magnetite headlights, self-contained solenoid-operated circuit breaker arranged for 650-volt operation, alternating current and direct current, rotary converter panels. Represented by C. E. Sprague, C. C. Peirce, J. J. Mahoney, H. D. Hawks, W. J. Clark, R. E. Moore, E. H. Ginn, H. C. Marsh, W. J. Hanley, H. L. Monroe, G. D. Rosenthal, Gen. Irving Hale, J. R. Lovejoy, J. G. Barry, C. E. Barry, H. N. Ransom, W. B. Potter, F. E. Case, E. D. Priest, A. H. Armstrong, E. H. Anderson, G. H. Hill, A. V. Thompson, F. H. Gale, Mr. Corbin, Mr. Buell.

The General Storage Company, Boonton, N. J., exhibited storage battery plates, jars, tanks and accessories in various sizes, "Bijur" regulator and switchboard. Represented by Joseph Bijur, James Dixon, Edward Lyndon.

G. M. Gest, New York, N. Y., exhibited cable racks, conduit and photographs of typical installations.

The Gold Car Heating and Lighting Company, New York, N. Y., showed the Gold improved electric car heaters, junction boxes and parts. Represented by E. E. Gold, E. B. Wilson, J. M. Stayman, F. T. Kitchen, F. Cahill.

The Gould Storage Battery Company, New York, N. Y., exhibited various types of Gould cells, lead-lined tanks. Represented by H. N. Powers, C. H. Bradley, H. W. Brow.

The H. W. Johns-Manville Company, New York, N. Y., exhibited high-tension catenary overhead line material, asbestos wood, indurated fibre third-rail insulators, battery jars, low-tension overhead line material, arc deflectors, high-tension porcelain insulators, Noark enclosed fuses, molded mica sockets, friction tape, splicing compound, electric car heaters, asbestos pipe and boiler covering, asbestos roofing and packing. Represented by T. F. Manville, J. W. Perry, T. L. Barnes, S. G. Meek, E. E. Schmid, J. McSorley, C. N. Manfred, H. M. Voorhis, G. A. Saylor, H. M. Frantz, R. R. Braggins, W. W. Power, C. W. Schultz, E. B. Hatch, W. H. Kempton.

The Lord Electric Company, New York, N. Y., exhibited Earll trolley retrievers and catchers, Thomas laminated soldered rail bonds, Shaw lightning arresters, Cosper controlators, Garton choke coils, Garton "Multi-Vapo-Gap" lightning arrester, cell and block type, Garton "Hydro Ground," Leco ground plates, points, cap and couplings, Leco car seat heat deflectors. Represented by F. Lord, E. Kirkham, W. R. Garton, E. A. Robertson, Ray P. Lee, C. A. Davis, W. P. Cosper.

The Massachusetts Chemical Company, Walpole, Mass., exhibited samples of Armalac, Enamelac, M. C. paint, insulating tapes, splicing compounds, Walpole insulating board, field coil cushions, motor bushings, switch board matting car steps, corrugated matting. Represented by L. O. Duclos, A. E. Duclos, F. J. Gleason, E. W. Furbush.

The Elmer P. Morris Company, New York, N. Y., exhibited line material, car trimmings and general repair parts. Represented by Elmer P. Morris, Dwight E. Morris, Fred W. Roth, H. S. Tonks.

The National Carbon Company, Cleveland, Ohio, exhibited a vibrating machine for testing carbon brushes. Represented by N. C. Cotabish, F. D. Kathe, O. T. Weaver, W. B. Brady, A. E. Carrier, A. C. Henry.

The Ohio Brass Company, Mansfield, Ohio, exhibited trolley hangers and ears, rail bonds, third-rail insulators, catenary materials, high-tension porcelain insulators, Tomlinson car couplers, Universal sander valves and traps, Collin steam pressure regulating valves. Represented by C. K. King, A. L. Wilkinson, G. A. Mead, E. F. Wickwire, A. L. Price, C. H. Tomlinson, N. M. Garland, R. M. Campbell, Nathan Shute, W. H. Bloss, F. E. Johnson, E. C. Brown, J. E. Slimp.

The Rail Joint Company, New York City, exhibited samples of rail joints. Represented by B. M. Barr, D. J. Evans, C. A. Cool, G. W. Smith.

The Speer Carbon Company, St. Marys, Pa., exhibited carbon brushes for motors and generators, circuit-breaker carbons. Represented by J. S. Speer, G. P. Fryling.

The Standard Paint Company, New York City, established a comfortable reception room. Represented by J. G. Satterthwait, Paul J. McCarley, Charles E. Smith.

The Standard Underground Cable Company, Pittsburg, Pa., exhibited cables, wires, junction boxes, cable terminals. Represented by H. P. Kimball, T. E. Hughes, C. W. Davis.

The Standard Varnish Company, New York, N. Y., exhibited samples of insulating specialties. Represented by L. Robinson, H. Chilcote, A. Steinberg, E. A. Holland.

The Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y., exhibited magneto despatching telephones, central energy despatching telephones and kindred equipments. Telegraph signals manufactured by Telegraph Signal Company, Rochester, N. Y. Represented by J. O. Oliver, H. W. Lucia, E. O. Munson, H. C. Slemin.

The Wagner Electric Manufacturing Company, St. Louis, Mo., exhibited single-phase and polyphase motors, switchboard and portable instruments. Represented by W. Robbins, E. W. Goldschmidt, John Mustard, Brooks Faxton.

The Western Electric Company, Chicago, Ill., exhibited overhead material, pole brackets, armature and field coils, commutators, arc lamps, safety strain insulators, high-tension and third-rail insulators, Kalamazoo trolley wheels, headlights, Deltabeston coils and wire. Represented by A. E. Meixell, H. M. Post, F. Killion, M. A. Oberlander, R. Roth, F. C. Jaeger, R. H. Harper.

The Westinghouse Electric and Manufacturing Company, Pittsburg, Pa., exhibited standard direct current forty-horse-power motors, direct current fifty-horse-power interpole motor, 150-horse-power motor, unit switch system of control for use on direct-current and alternating-current railways, single-phase motors. Represented by J. A. Brett, W. N. Conwell, C. S. Cook, Thomas Cooper, C. H. Davis, H. P. Davis, T. W. Ewing, G. B. Griffin, W. M. McFarland, L. N. Reed, C. W. Register, H. C. Stier, C. B. Humphrey, J. C. McQuiston.

The Westinghouse Machine Company, East Pittsburg, Pa. Represented by E. H. Sniffin, L. L. Brinsmade, L. C. Bullington, H. H. Van Blarcom, J. H. Wagenhorst, R. E. Adreon, G. M. Bates.

The Westinghouse Traction Brake Company, Pittsburg, Pa., had an operating exhibit of equipments suitable for single motor car, two car trains consisting of motor and trailer, and three to five car trains; sectional motor-driven compressor; sectional brake cylinder with slack adjuster. Represented by A. L. Humphrey, J. R. Ellicott, C. R. Ellicott, E. L. Adreon, S. D. Hutchins, P. H. Donovan, Robert Burgess, A. Johnson, C. P. Cass, C. W. Townsend, E. A. Craig, F. M. Nellis, F. V. Green, C. J. Olmstead, A. Johnson, W. V. Turner, J. F. Miller and W. S. Bartholomew.

Current Electrical News

DOMESTIC AND EXPORT.

VIRGINIA WATER-POWER DEVELOPMENT—The Talley's Falls Improvement Company, M. R. Lewis engineer-in-charge, is planning the development of the water power of Talley's Falls, on Dan River, five miles from Scottsburg, Va. From 10,000 to 12,000 horse-power will be available for transmission to manufacturing plants in Virginia and North Carolina, including copper-mining properties in the Virginia-Carolina copper belt. Reports state that $1,000,000 will be the cost of the dam, electric plant and transmission lines.

$1,000,000 BONDS ISSUED BY MILWAUKEE ELECTRIC RAILWAY AND LIGHT COMPANY—Spencer Trask & Company and N. W. Harris & Company, of New York, have purchased jointly $1,000,000 Milwaukee Electric Railway and Light Company refunding four and one-half per cent bonds, due 1931. These bonds are being issued by the company to refund a like amount of Milwaukee City Railway fives, due December 1, 1908. The refunding four and one-half per cent bonds are being offered to investors at ninety-five and interest.

TO HAUL ORE BY ELECTRICITY—An effort is being made by the Arizona Mercantile, Transportation and Smelter Company, of Leavenworth, Kan., to obtain a concession from the Mexican Government for the construction of a standard-gauge electric railroad from some point on the Southern Pacific Railroad in Arizona, probably Maricopa, to the Gulf of California at St. George's Bay, cutting the distance from Central Arizona points to deep water a distance of 160 miles. It is proposed by means of this road to haul ore from the mines to deep water.

DES MOINES ELECTRIC COMPANY TO ENLARGE PLANT—Plans for the extension of its plant involving the expenditure of $1,000,000 have been announced by General Manager Paul B. Sawyer, of the Des Moines Edison Light Company, Des Moines, Iowa, hereafter to be known as the Des Moines Electric Company. This announcement comes as a culmination of recent changes in the incorporation of that concern, as announced recently. While the authorized capital stock of the new company is $5,000,000, the stock actually issued is exactly the amount of the Des Moines Edison Light Company stock outstanding, or $1,125,000. The remaining stock not issued is to provide in part the funds for the future growth of the company. The bonds issued at this time are of such amount as is needed to take up the outstanding indebtedness of the old Des Moines Edison Light Company, $730,000, and to pay in addition for improvements already in progress and contemplated for the year 1908.

NEW MONTANA POWER PLANT TO SUPPLY POWER TO MINES—Between $2,500,000 and $3,000,000 is to be expended in the construction of a new power line from Thompson, Mont., to the Murray district. This project has been in the hands of Senator Donlan, of Missoula, Mont., for some time and arrangements for financing has been completed. Construction work will soon be commenced. The plant will furnish power to the northside mines. From Thompson to Murray the line will be approximately thirty-one miles in length, the right of way having all been secured. Engineers estimate that even in the driest seasons no less than 29,000 horsepower will be generated, 18,000 above Thompson Falls and 11,000 below. The right of way runs west to Mullan and Wallace. One branch goes to Burke and another down Pritchard Gulch to Pritchard Creek will furnish power to Paragon, Chicago-London, Jewell-Jewell, Black Horse, Bear Top, Golden Chest, Terrible Edith, Pilot and many other properties.
